THE ENCYCLOPÆDIA BRITANNICA

FOURTEENTH EDITION

VOLUME 19

RAYNAL TO SARREGUEMINES

RAYNAL, GUILLAUME THOMAS FRANÇOIS (1713–1796), French writer, was born at Saint Geniez, Rouergue, on April 12, 1713. He was educated at the Jesuit school of Pezenas, and received priest's orders, but he was dismissed for unexplained reasons from the parish of Saint-Sulpice, Paris, to which he was attached, and thenceforward he devoted himself to society and literature. The Abbé Raynal wrote for the *Mercure de France,* and compiled a series of popular but superficial works, which he published and sold himself. These—*L'Histoire du stathoudérat* (The Hague, 1748), *L'Histoire du parlement d'Angleterre* (London, 1748), *Anecdotes historiques* (Amsterdam, 3 vols., 1753)—gained for him access to the salons of Mme. Geoffrin, Helvétius, and the baron d'Holbach. He had the assistance of various members of the *philosophe* coteries in his most important work, *L'Histoire philosophique et politique des établissements et du commerce des Européens dans les deux Indes* (Amsterdam, 4 vols., 1770). Diderot indeed is credited with a third of this work, which was characterized by Voltaire as "du réchauffé avec de la declamation." The other chief collaborators were Pechméja, Holbach, Paulze, the farmer-general of taxes, the Abbé Martin, and Alexandre Deleyre. The "philosophic" declamations constituted its chief interest for the general public, and its significance as a contribution to democratic propaganda. The *Histoire* went through many editions, being revised and augmented from time to time by Raynal; it was translated into the principal European languages, and appeared in various abridgments. Its introduction into France was forbidden in 1779; the book was burned by the public executioner, and an order was given for the arrest of the author, whose name had not appeared in the first edition, but was printed on the title page of the Geneva edition of 1780. Raynal escaped to Spa, and thence to Berlin, where he was coolly received by Frederick the Great, in spite of his connection with the *philosophe* party. At St. Petersburg he met with a more cordial reception from Catherine II., and in 1787 he was permitted to return to France, though not to Paris. He was elected by Marseilles to the States-general, but refused to sit on the score of age. Raynal now realized the impossibility of a peaceful revolution, and, in terror of the proceedings for which the writings of himself and his friends had prepared the way, he sent to the Constituent Assembly an address, which was read on May 31, 1791, deprecating the violence of its reforms. This address is said by Sainte-Beuve (*Nouveaux lundis,* xi.) to have been composed chiefly by Clermont Tonnerre and Pierre V. Malouet, and it was regarded, even by moderate men, as ill-timed. The published *Lettre de l'abbé Raynal à l'Assemblée nationale* (Dec. 10, 1790) was really the work of the comte de Guibert. During the Terror Raynal lived in retirement at Passy and at Montlhéry. On the establishment of the Directory in 1795 he became a member of the newly organized Institute of France. He died in the next year on March 6, at Chaillot.

A detailed bibliography of his works and of those falsely attributed to him will be found in Quérard's *La France littéraire,* and the same author's *Supercheries dévoilées. See* also the anonymous *Raynal démasqué* (1791); B. Lunet, *Biographie de l'abbé Raynal* (Rodez, 1866); and J. Morley, *Diderot* (1891).

RAYNAUD'S DISEASE, a malady first described by P. Edouard Raynaud in 1862 in a paper on "Local Asphyxia and Symmetrical Gangrene of the Extremities." It is a disease of childhood or early adult life, and females are more frequently affected than males. Raynaud attributed the symptoms to an arrest of the passage of blood to the affected parts, and considered this due to a spasm of the arterioles. That the skin capillaries in the various stages correspond with this view has been shown by G. E. Brown but the more fundamental aetiology is unknown. If the spasm be sufficiently prolonged and intense to close completely the arterial channels, gangrene of the part may result.

The local symptoms are divided into three well-marked stages. The first is *local syncope,* in which the affected parts become temporarily bloodless, white, cold and anaesthetic. The condition is familiar in what is termed a "dead finger," and is usually bilateral. After a variable time the circulation may become restored with a tingling sensation, or the disease may progress to the second stage, that of *local asphyxia.* In this condition some part of the body, usually a finger, toe or the whole hand or foot, becomes painful, bluish-purple or mottled, and cold. The discoloration may deepen until the skin is almost black, the tactile sense being lost. After several hours, the attack may pass off. Such attacks of local asphyxia may return every day for a time. Sometimes severe abdominal pain is present, accompanied by haematuria. In the third stage, that of *local gangrene,* the involved areas assume a black and shrivelled appearance, livid streaks marking the course of the arteries; blebs may form containing bloody fluid. The degree of destruction varies from the detachment of a patch of soft tissue down to the loss of even a whole limb, the part becom-

ing separated by a line of demarcation as in senile gangrene.

In Raynaud's disease the patients have been noticed to be very susceptible to cold; the extremities must be kept warm; and the activity of the circulation roused by douches and exercise; by these means an attack may be prevented. Should local asphyxia have taken place, one of the best treatments to lessen pain and obtain the return of the natural colour is the application of the constant current, the limb being placed in a bath of warm salt and water. Cushing's method of inducing active hyperaemia has been attended with much success. This treatment is only applicable when the vascular spasm affects the extremities, and consists in the artificial constriction of the limb by the application of a tourniquet or Esmarch's bandage for a few minutes daily. This is followed by hyperaemia and increased surface temperature, and affords much relief to the pain of the stage of asphyxia. Drugs which dilate the peripheral vessels, such as amyl nitrite and trinitrine, have also been recommended. The disease tends towards recovery with more or less loss of tissue if the stage of gangrene has been reached.

See G. E. Brown, Arch. Int. Med., 1925, xxxv. 56.

RAYNOUARD, FRANÇOIS JUSTE MARIE (1761–1836), French dramatist and *savant*, was born at Brignoles (Provence), on Sept. 8, 1761. He was educated for the bar and practised at Draguignan. In 1791 he went to Paris as deputy to the Legislative Assembly, but after the fall of the Girondists, he was imprisoned in Paris. During his imprisonment he wrote his play *Caton d'Utique* (1794). *Eléonore de Bavières* and *Les Templiers* were accepted by the Comédie Française. *Les Templiers* was produced in 1805, and, in spite of the protests of Geoffroy, had a great success. Raynouard was admitted to the Academy in 1807, and from 1817 to 1826 he was perpetual secretary. He was admitted to the Academy of Inscriptions in 1815. His later life was spent in studying the Provençal language and literature. His chief works are *Choix de poésies originales des troubadours* (6 vols., 1816–1821), of which the sixth volume, *Grammaire comparée des langues de l'Europe latine dans leurs rapports avec la langue des troubadours* (1821), was separately published; and *Lexique roman* (6 vols., 1838–1844). He died at Passy on Oct. 27, 1836.

RAYON. This word was first used as a textile term in the United States in the year 1924 and is the name by which some of the synthetic fibres, frequently called artificial silk in Great Britain, are commonly known in the United States. For processes, products, statistics, etc., *see* SILK, ARTIFICIAL; CELLULOSE.

The technical definition usually accepted (U.S. Dept. of Commerce) is as follows: *Rayon* is the generic name of filaments made from various solutions of modified cellulose by pressing or drawing the cellulose solution through an orifice and solidifying it in the form of a filament or filaments, by means of some precipitating medium.

RAYONNANT STYLE, in architecture, the fully developed French Gothic style (*see* GOTHIC ARCHITECTURE) of the latter half of the 13th and the first three quarters of the 14th centuries. It is characterized by a complete mastery of the structural ideas of the Gothic vaulted church; great skill in stone cutting; the elimination of wall surface; the reduction in area of all supports to the minimum; thorough development and lavish use of bar tracery based on geometric forms; reduction in size and importance of the triforium gallery, and a general attempt to accent all vertical lines. In carved ornament the spherical crocket of the earlier Gothic was replaced by a fully opened, upturned leaf, and naturalistic foliage decorated capitals, string courses and the like. Figure sculpture was lavishly used around entrance doors, and in its combination of decorative validity and realistic presentation, it approached Greek sculpture of the 4th century B.C. Towards the end of the period, realism in sculpture became dominant and the decorative value of the work diminished. Characteristic examples are: later portions of Amiens cathedral (apse completed 1269, side chapels 1292–1375); transept and side chapels of Notre Dame at Paris (1258–1315); Sainte Chapelle, Paris (1245–48); S. Urban at Troyes (1262–76), famous for its delicate tracery and enormous window area; the Portail des Libraires at Rouen cathedral (1280); and the east end of the great abbey church of S. Ouen at Rouen (choir and transepts begun 1318).

RAZIN, STENKA [STEPHEN TIMOFEEVICH] (d. 1671), Cossack hetman and rebel, whose parentage and date and place of birth are unknown. We first hear of him in 1661 on a diplomatic mission from the Don Cossacks to the Kalmuck Tatars, and in the same year we meet him on a pilgrimage of a thousand miles to the great Solovetsky monastery on the White Sea "for the benefit of his soul." After that all trace of him is lost for six years, when he reappears as the leader of a robber community established at Panshinskoe, among the marshes between the rivers Tishina and Ilovlya, from whence he levied blackmail on all vessels passing up and down the Volga. His first considerable exploit was to destroy the "great water caravan" consisting of the treasury-barges and the barges of the patriarch and the wealthy merchants of Moscow. He then sailed down the Volga with a fleet of thirty-five galleys, capturing the more important forts on his way and devastating the country. At the beginning of 1668 he defeated the voivode Jakov Bezobrazov, sent against him from Astrakhan, and in the spring embarked on a predatory expedition into Persia which lasted for eighteen months. Sailing into the Caspian, he ravaged the Persian coasts from Derbend to Baku, massacred the inhabitants of Resht, and in the spring of 1669 established himself on the isle of Suina, off which, in July, he annihilated a Persian fleet sent against him. Stenka, as he was generally called, had now become a potentate with whom princes did not disdain to treat. In August 1669 he reappeared at Astrakhan, and accepted a fresh offer of pardon from the tsar there. In 1670 Razin rebelled against the government, captured Cherkask, Tsaritsyn and other places, and on June 24 burst into Astrakhan. After massacring all who opposed him, and giving the rich bazaars of the city over to pillage, he converted Astrakhan into a Cossack republic. After a three weeks' carnival of blood and debauchery Razin quitted Astrakhan with two hundred barges full of troops to establish the Cossack republic along the whole length of the Volga, as a preliminary step towards advancing against Moscow. But his forces were stayed by the resistance of Simbirsk, and after two bloody encounters close at hand on the banks of the Sviyaga (October 1st and 4th), Razin was ultimately routed and fled down the Volga.

But the rebellion was by no means over. The emissaries of Razin, armed with inflammatory proclamations, had stirred up the inhabitants of the modern governments of Nizhniy-Novgorod, Tambov and Penza, and penetrated even so far as Moscow and Great Novgorod. It was not difficult to rouse the oppressed population by the promise of deliverance from their oppressors. Razin proclaimed that his object was to root out the boyars and all officials, to level all ranks and dignities, and establish Cossackdom, with its corollary of absolute equality, throughout Muscovy. Even at the beginning of 1671 the issue of the struggle was doubtful. Eight battles had been fought before the insurrection showed signs of weakening, and it continued for six months after Razin had received his quietus. At Simbirsk his prestige had been shattered. Even his own settlements at Saratov and Samara refused to open their gates to him, and the Don Cossacks, hearing that the patriarch of Moscow had anathematized Stenka, also declared against him. In 1671 he was captured at Kagalnik, his last fortress, and carried to Moscow, where, on June 6, after bravely enduring unspeakable torments, he was quartered alive.

See N. I. Kostomarov, *The Rebellion of Stenka Razin* (Rus.) (2nd ed. Petersburg, 1859); S. M. Solovev, *History of Russia* (Rus.), vol. ii. (Petersburg, 1895, etc.); R. N. Bain, *The First Romanovs* (London, 1905). (R. N. B.)

RAZMAK, the new military cantonment opened in Waziristan after the suppression of the Waziristan rebellion which followed the third Afghan war. It is some 6,000 feet above the sea and 13 miles from the old military frontier of Bannu, and is occupied by mixed forces.

RAZOR. The ordinary razor is an instrument used for shaving and consists of a hardened steel blade, made with an extremely fine sharp edge and fitted into a handle.

The early razor of modern times was made of steel which had a wedge-shaped section, with straight sides tapering to a sharp

edge, and although simple in form it was an extremely good and useful instrument for its purpose. It possessed very durable properties, lasting in many cases the whole lifetime of its owner.

In the early part of the last century, the practice was introduced of hollowing out the sides of the blade by grinding, the idea being to facilitate the process of sharpening and re-sharpening the blade, and to improve the fineness of the cutting edge. At first the degree of hollowness, or concavity of the sides of the blade was only small, but in more recent times with great skill, hollow-grinding has been carried considerably further, increasing the lightness and flexibility of the blade. The full hollow blade is actually thinner in the centre of the blade than nearer the cutting edge, and such a hollow ground blade can be made to give a resonant ring. The process of hollow-grinding is performed by using grinding wheels of successively diminishing diameters.

The processes of the production of the blade consist of:—the forging under the hammer, marking with the name of the maker, drilling the hole for the pin, then the hardening and tempering of the blade, the grinding and hollowing as above described, the glazing and buffing on small leather-covered wheels with suitable polishing material. The blade is then etched, fitted with a handle and finally whetted to a fine sharp edge. The process of etching is sometimes a very elaborate one, some beautiful effects on the etched surface of the blade being obtained.

Safety Razor.—The razor is naturally considered a dangerous instrument, and many attempts have been made to make it entirely safe for its purpose. It was not until the introduction of the "Gillette" type of razor, at the beginning of this century, that a satisfactory solution was found. The principle of the "safety" type of razor, is to place a guard between the skin and the cutting edge of the razor blade, so that the guard permits the edge of the razor to pass over the uneven surface of the part to be shaved removing the hair but without cutting the skin.

The blade of the safety type of razor is generally made out of very thin sheet or strip steel of the finest quality for its purpose, and the fine cutting edges of the blade are formed by whetting on suitable wheels.

In some cases devices are provided to enable the user to strop or re-sharpen the blades, and the action applied in this operation, when used after shaving, enables the blade to be effectively cleaned and dried at the same time, thereby preventing corrosion of the fine edge and preserving it for future use. The quality of the steel strip supplied by the steel-maker for ultimate use as blades in the safety-razor, is the result of a combination of the highest grade of skill and experience both on the part of the steel-maker and of the rolling-mill engineer.

Other types of safety devices have been introduced which are based on the desire to retain the general form and make up of the ordinary razor, while rendering it as safe in use as the more modern type. These take the form of the fitting of a suitable guard to the blade of the ordinary razor, or the substitution for it of a holder, carrying an adjustable blade of the strip-steel type, in place of the ordinary blade.

The modern type of "safety-razor" has revolutionized the practice of domestic shaving, reducing the operation to the simplest possible form, but the ordinary razor still holds its own, in the judgment of the professional barber, as the most convenient all-round instrument for its purpose. (W. R.)

RAZORBILL or **RAZOR-BILLED AUK,** *Alca torda,* a member of the Auk family, known also as Marrot, Murre, Scout, Tinker or Willock; some of these names it shares with the GUILLEMOT (*q.v.*), and PUFFIN (*q.v.*). It is a common sea-bird of the north Atlantic, resorting in vast numbers to certain rocky cliffs for breeding, and returning to the open sea for the rest of the year. It is in many respects intermediate between the guillemot and the garefowl (*q.v.*). In habits the razorbill agrees with the guillemots, laying its single egg on ledges of cliffs. It breeds on both sides of the north Atlantic, wandering as far south as the Mediterranean on the east and Long Island on the west in winter. It feeds on fish.

RÉ, ÎLE DE, an island of western France, belonging to the department of Charente-Inférieure, distant about 2 m. from the mainland. The island has an area of nearly 33 sq.m., with a breadth varying from 1 to 4½ m. and a length of 15 m. It is separated from the coast of Vendée on the N. by the Pertuis Breton, some 6 m. broad, and from the island of Oléron on the S. by the Pertuis d'Antioche, 7½ m. broad. The coast facing the Atlantic is rocky, but there are several harbours on the landward side, of which the busiest is La Flotte. In the north-west of the island there is a deep gulf, the Fier d'Ars, which leaves an isthmus only 230 ft. wide, strengthened by a breakwater. The north coast is fringed by dunes and by salt-marshes. Industries are fishing, oyster-cultivation and the collection of seaweed for manure; the island has corn-lands and vineyards and grows early vegetables. There are two cantons, St. Martin (pop. in 1926, 6,478) and Ars-en-Ré (pop. 3,562) forming part of the arrondissement of La Rochelle. St. Martin, the capital, which has a safe harbour, was fortified by Vauban in 1681.

REA, SAMUEL (1855–1929), American railroad official, was born at Hollidaysburg (Pa.), on Sept. 21, 1855. In 1871 he entered the service of the Pennsylvania Railroad as chainman and rodman. From 1875 to 1877 he was assistant engineer on construction of the Monongahela river bridge at Pittsburgh. He was next appointed assistant engineer for the Pittsburgh and Lake Erie Railroad and returned to the Pennsylvania lines in 1879 in a similar capacity. In 1888 he was appointed assistant to the second vice president of the Pennsylvania Railroad, which position he retained until 1889 when he was made chief engineer on construction of the belt line tunnel under Baltimore for the Baltimore and Ohio Railroad.

In 1892 he again returned to the Pennsylvania Railroad as assistant to the president, and became first vice president in 1911. In 1913 he was elected president. He was in charge of the construction of the Pennsylvania Station in New York city (completed in 1910), the connecting tunnels under the Hudson and East rivers, the New York Connecting Railroad and Hell Gate bridge over the East river (opened in 1917). In 1917 he became a member of the executive committee on national defence of the American Railway Association, known as the Railroads War Board. He retired from the presidency on Sept. 30, 1925, but continued as a director of the Pennsylvania Railroad and various subsidiary companies. He wrote *The Railways Terminating in London* (1888).

READE, CHARLES (1814–1884), English novelist and dramatist, the son of an Oxfordshire squire, was born at Ipsden, Oxfordshire, on June 8, 1814. He entered Magdalen college, Oxford, proceeded B.A. in 1835, and became a fellow of his college. He was subsequently dean of arts, and vice-president of Magdalen college, taking his degree of D.C.L. in 1847. His name was entered at Lincoln's Inn in 1836; he was elected Vinerian fellow in 1842, and was called to the bar in 1843. He kept his fellowship at Magdalen all his life, but after taking his degree he spent the greater part of his time in London. He began his literary career as a dramatist, and it was his own wish that the word "dramatist" should stand first in the description of his occupations on his tombstone. He was dramatist first and novelist afterwards, not merely chronologically but in his aims as an author, always having an eye to stage-effect in scene and situation as well as in dialogue.

His first comedy, *The Ladies' Battle,* appeared at the Olympic Theatre in May 1851. It was followed by *Angelo* (1851), *A Village Tale* (1852), *The Lost Husband* (1852), and *Gold* (1853). But Reade's reputation was made by the two-act comedy, *Masks and Faces,* in which he collaborated with Tom Taylor. It was produced in Nov. 1852, and later was expanded into three acts. By the advice of the actress, Laura Seymour, he turned the play into a prose story which appeared in 1853 as *Peg Woffington* as did also *Christie Johnstone,* a close study of Scottish fisher folk. In 1854 he produced, with Tom Taylor, *Two Loves and a Life* and *The King's Rival;* and, unaided, *The Courier of Lyons*—well known under its later title, *The Lyons Mail*—and *Peregrine Pickle.* In the next year appeared *Art,* afterwards known as *Nance Oldfield.*

He made his name as a novelist in 1856, when he produced *It's Never Too Late to Mend,* a novel written with the purpose of reforming abuses in prison discipline and the treatment of

criminals. Five minor novels followed in quick succession,—*The Course of True Love never did run Smooth* (1857), *Jack of all Trades* (1858), *The Autobiography of a Thief* (1858), *Love Me Little, Love Me Long* (1859), and *White Lies* (1860), dramatized as *The Double Marriage*. Then appeared in 1861, his masterpiece, *The Cloister and the Hearth*, relating the adventures of the father of Erasmus; it is undoubtedly one of the finest historical novels in existence. Returning from the 15th century to modern English life, he next produced another startling novel with a purpose, *Hard Cash* (1863), in which he strove to direct attention to the abuses of private lunatic asylums. Three other novels "with a purpose" were *Foul Play* (1869), in which he exposed the iniquities of ship-knackers, and paved the way for the labours of Samuel Plimsoll; *Put Yourself in his Place* (1870), in which he grappled with the trades-unions; and *A Woman-Hater* (1877), on the degrading conditions of village life. The *Wandering Heir* (1875), of which he also wrote a version for the stage, was suggested by the Tichborne trial.

Outside the line of these moral and occasional works Reade produced three elaborate studies of character,—*Griffith Gaunt* (1866), *A Terrible Temptation* (1871), *A Simpleton* (1873). The first of these was in his own opinion the best of his novels. His greatest success as a dramatist attended his last attempt—*Drink*—an adaptation of Zola's *L'Assommoir*, produced in 1879. In that year his friend Laura Seymour, who had kept house for him since 1854, died. Reade's health failed from that time, and he died on April 11, 1884, leaving behind him a completed novel, *A Perilous Secret*, which showed no falling off in the arts of weaving a complicated plot and devising thrilling situations. Reade was an amateur of the violin, and among his works is an essay on Cremona violins with the title, *A Lost Art Revived*.

It was characteristic of Reade's open and combative nature that he admitted the public freely to the secrets of his method of composition. By his will he left his workshop and his accumulation of materials open for inspection for two years after his death. He had collected an enormous mass of materials for his study of human nature, from personal observation, from newspapers, books of travel, blue-books of commissions of inquiry, from miscellaneous reading. This vast documentation, and Reade's use of it, shows him as a precursor of the school of Zola.

See Charles L. Reade and Compton Reade, *Charles Reade, a Memoir* (2 vols., 1887); A. C. Swinburne, *Miscellanies* (1886); John Coleman, *Charles Reade as I knew him* (1903); Walter C. Phillips, *Dickens, Reade and Collins, Sensation Novelists* (1919).

READING, RUFUS DANIEL ISAACS, 1ST MARQUESS OF (1860–), British statesman, was born on Oct. 10, 1860, in London, the second son of Joseph Isaacs, merchant. He was educated at University college school, London, and abroad. At the age of 14 he ran away to sea, and served two years before the mast in a sailing ship. A subsequent venture on the Stock Exchange was a failure. He then read for the bar, and was called in 1887; the same year he married Miss Alice Cohen. His legal career was one of unbroken and immediate success. Perhaps the most sensational of his cases was the prosecution of Whitaker Wright for fraud, which was followed by the defendant's suicide.

He entered parliament as a Liberal Imperialist, winning a seat for his party at Reading in a by-election in 1904, which he retained till he went to the House of Lords. In political oratory, although an effective speaker in the country, he failed, as so many great lawyers have failed, to impress the House of Commons, being far more inclined to address his opponents as a jury with a view to their conversion than to stimulate enthusiasm for the policy of his own party. But his party had the highest opinion of him and he became attorney-general in 1910, and in 1912 was given a seat in the cabinet; which no attorney-general had held before. Then followed the great Marconi shares scandal, in which he and Lloyd George were alleged to be involved. The substance of the charge was that he had bought American Marconi shares, some of which he sold to Lloyd George, while the British Marconi company was contracting with the Government. It was investigated by a committee of the House and his reputation was certainly vindicated. A few months later (Oct. 20, 1913) he was made lord chief justice, and created Baron Reading of Erleigh. In this office he distinguished himself by humanity in the conduct of criminal cases and by the establishment of the principle that the court of criminal appeal should act as a real court of revision, upsetting verdicts or reducing sentences even of the individual high court judges. He presided over the trial of Casement in Ireland during the World War.

After the outbreak of the war in Aug. 1914, he assisted in the drafting and the administration of those measures which saved England from financial ruin. The most sensational of these was the granting of the British guarantee to the great accepting houses, to bills amounting to many hundred millions of pounds. In 1915 he was president of the Anglo-French Loan Commission to the United States, where he succeeded in floating a great war loan. On June 26, 1916, he was created Viscount Reading of Erleigh.

In 1917 he was appointed high commissioner and special envoy to the United States, and in December of that year was created an earl. In 1918 he was appointed high commissioner and special ambassador at Washington.

Lord Reading's term as viceroy of India began at the end of the war. He was faced immediately by four acute problems. First the diarchy system of the Montagu-Chelmsford Government of India Act, devised as a step in advance towards complete self-government, was definitely rejected by the leaders of the united Hindu and Mohammedan educated population, who in the movement known as Swaraj had resolved to make it unworkable. The second was the influence of Mahatma Gandhi, one of the most remarkable men of all time, who had inflamed millions of Indians to a boycott of the West by the East and a kind of gigantic movement of passive resistance, in which both English products and English Government were to be alike rejected. The third was that the national temper of India had been aroused by prohibitions and indignities put upon Indians in other parts of the empire. The fourth, the ghastly story of the Punjab rebellion and the slaughter at Amritsar in 1919, with the support of Gen. Dyer's action there by the governing classes in England, had excited a feeling of such fierce resentment throughout the length and breadth of the peninsula as might well have caused a general uprising. In dealing with the revolt against the diarchy, he found himself compelled to imprison the two Mohammedan leaders, the brothers Ali. And although he was able before the end to establish some kind of self-government in most of the local provinces and even something like friendly co-operation in the Central Legislative council the constitution broke down in the Central Provinces and had to be suspended in Bengal, with a return to complete autocratic government. In the case of the boycott of the West the viceroy, after several attempts at reconciliation with Gandhi, authorized his prosecution for inciting to mass civil disobedience which resulted in a sentence of six years' imprisonment, although the mahatma was released on the grounds of ill health after two years.

In the matter of the treatment of Indian immigrants in other parts of the empire, Lord Reading showed himself a determined supporter of the rights of India. In the case of Amritsar and the memories of the rebellion he could only exhibit his sympathy with the Indian population and work for the healing influences of time.

In the struggle for financial stability he was compelled to exercise the power of certification by the viceroy against the Assembly of the much-hated salt tax. But he saw, and acquiesced in, India, like many other of the dominions, converting itself from a free trade into a protectionist country, a change produced partly by a passionate nationalism which rejected the excise cotton duties, and partly by the need for compensating revenues by a big import duty on iron and steel. That he could exercise sternness when required was shown by his action towards the maharajah of Indore, who was compelled to abdicate as an alternative to trial by his peers for the murder of an Indian merchant. Upon his return to England in April 1926 he was raised to the rank of marquess. (*See* INDIA.)

READING, a county borough and county town of Berkshire, England, 36 m. W. by S. of London by the G.W.R. Pop. (1921) 92,278.

Reading early became a place of importance. In 871 the Danes encamped here, and in 1006 it was burned by Sweyn. It consisted of only 30 houses at the time of the Domesday Survey. It is thought that a fortification existed there before the Conquest, and Stephen built a masonry castle which Henry II. destroyed. On the foundation of Reading abbey the town, hitherto demesne of the crown, was granted to the abbey by Henry I. Henceforth, until the 16th century, its history was that of the struggle as to rights and privileges between the abbey and the merchant gild. A 16th-century account of the gild merchant shows that many trades were then carried on, but Leland says the town "chiefly stondith by clothing." By the 17th century the trade began to decline; the bequest of Kendrich did little to revive it, and it was greatly injured by the Civil War. In the 18th century the chief trade was in malt. The first town charter is that given by Henry III. (1253) confirmed and amplified by succeeding sovereigns. The governing charter until 1835 was that of Charles I. (1639) incorporating the town under the title of the mayor, aldermen and burgesses. The town surrendered to the parliamentary troops, after a siege, in 1643; it was occupied subsequently by the forces of both parties: in 1688 a skirmish took place in the town between some Irish soldiers of James II. and the troops of William of Orange. The market, chiefly held on Saturday, can be traced to the reign of Henry III.; four fairs granted by the charter of 1562 are still held.

Reading is an important junction on the G.W.R. and has communication southward by the S.R. The Kennet and Avon canal, to Bath and Bristol, and the Thames, afford it connections by water. It lies on the Thames where the Kennet joins the main river. All the ancient churches are restored. Greyfriars church, formerly monastic, was completed early in the 14th century; and after the dissolution of the monasteries served successively as a town hall, a workhouse and a gaol, being restored to its proper use in 1864. St. Mary's was rebuilt in 1551 from the remains of a nunnery founded by Aelfthryth in expiation of the murder of her stepson Edward the Martyr. St. Lawrence's is a Perpendicular building, and St. Giles's was much damaged during the siege of 1643 by the parliamentary forces, and is almost wholly rebuilt. A Benedictine abbey was founded in 1121 by Henry I., with a church among the largest in the country. By Henry VIII. the abbey was converted into a palace, which was destroyed during the civil wars. The greater part of the site is occupied by public gardens.

A University College was opened in 1892 and affiliated to Oxford; its success led to the gathering of an endowment fund and it became an independent university with a charter in 1926. Its agricultural researches have been of special importance. The grammar school, founded in 1485, occupies modern buildings. There are also a blue-coat school (1656), and other charitable schools of early foundation. The municipal museum, besides an art gallery and other exhibits, includes a collection of Romano-British relics from Silchester.

Reading is a railway centre and an agricultural centre with famous nursery gardens. The industry for which it is chiefly famous is biscuit manufacture. There are also iron foundries, engineering works and factories for agricultural implements, and manufactures of tin boxes, potteries, sauces, velvet and silk, and sacking, together with riverside boat-building yards. Reading gives title to a suffragan bishopric in the diocese of Oxford. The parliamentary borough returns one member. A new bridge over the Thames to Caversham was opened in 1923, and the old one adjacent was closed for rebuilding in 1925.

READING, a town of Middlesex county, Massachusetts, U.S.A., 12 m. N. by W. of Boston, on the Boston and Maine railroad. Pop. (1920) 7,439 (84% native white); 1928 local estimate 9,000. It has numerous manufactures, including shoes, rubber goods, radio outfits, instruments for the deaf and organ pipes. The town was set off from Lynn and incorporated in 1644.

READING, a village of Hamilton county, Ohio, U.S.A., on the Pennsylvania railroad, 12 m. N. of Cincinnati. Pop. (1920) 4,540 (91% native white). The principal industries are the manufacture of glass, matches and fireworks. About 800 of the residents are employed outside the village. Reading was founded in 1797 and incorporated in 1851.

READING, a city of south-eastern Pennsylvania, U.S.A., the county seat of Berks county; on the Schuylkill river, 58 m. N.W. of Philadelphia. It is on Federal highways 22, 222, 422 and 120; has a municipal airport; and is served by the Pennsylvania and the Reading railways, interurban trolleys, motorbus and truck lines. Pop. (1920) 107,784 (90% native white); 1928 local estimate 115,400. An unusually large proportion of the population (88% in 1920) are natives of the State, and the "Pennsylvania German" element predominates. The city occupies 9·5 sq.m. on the east bank of the river, at an altitude ranging from 242 to 1,100 feet. To the east rises Mt. Penn (1,100 ft.) and to the south Neversink mountain (878 ft.). There are several summer hotels and sanatoria on the neighbouring hills. The city's parks and playgrounds cover 600 acres. Penn Common (50 ac.) is a recreation ground in the heart of the city, reserved for the public when the town was laid out. On the eastern slope of Mt. Penn is a park of 63 ac. and a boulevard winds along the southern slope of the mountain to the pagoda on the summit, which commands a wide view of the surrounding country. Among the interesting landmarks in the environs are several colonial farmhouses, the Conrad Weiser farm and sites of early forts and iron furnaces.

The public-school system comprises continuation, evening and summer schools, in addition to the usual instruction from kindergarten through high school. Pennsylvania State college and the University of Pennsylvania maintain extension centres in Reading, and it is the seat of Schuylkill college (Evangelical; 1926). The public library contains over 50,000 volumes and has three branch stations; the county historical society has a building full of interesting exhibits; and the public museum and art gallery occupy a beautiful new building, completed in 1926. Among the displays in the museum is a fine private collection of butterflies, owned by the curator. The city supports a symphony orchestra. It is also noted for the cultivation of rare peonies and irises. There are two daily papers; weeklies published in Polish and Italian and one devoted to the interests of labour and socialism; and the monthly organ of the retail coal merchants of Pennsylvania.

Reading has operated under a commission form of government since 1912. It is the centre of Pennsylvania's first super-power system, which supplies electric current to the region extending from Harrisburg to eastern New Jersey. The water-supply is filtered mountain water, stored in reservoirs with a capacity of 216,000,000 gal., and the city's daily consumption averages 20,000,000 gallons. The assessed valuation of property for 1927 was $161,260,000. Reading has a large retail and wholesale trade, and is an important shipping point for agricultural produce. It is within a short haul of the anthracite fields, and also of some of the richest bituminous coal-fields of the State. The classification yards of the Reading company are a vast distributing centre for anthracite shipments consigned to the East, West and South. Industrially, Reading ranks third among the cities of Pennsylvania, with an output in 1925 valued at $132,405,067. There are some 700 manufacturing establishments in the city and its immediate suburbs, including the shops of the Reading railway, and the largest plants in the country producing wrought iron pipe, glove-silk underwear, full-fashioned hosiery, glass door-knobs, goggles, optical goods, children's shoes, narrow silk fabrics, and certain kinds of hosiery knitting machines and lace-making machinery. Reading is the principal centre in the country for the manufacture of wool felt hats, and ranks second in the production of hosiery and knit goods and builders' hardware. There is a large proportion of skilled mechanics in the population, and many of the trades are organized. The proportion of women employed is relatively large (30·5% of all ten years of age and over in 1920); the proportion of boys and girls (10 to 15 years of age) working for wages is 13% and the proportion attending school is also high (68% of all 7 to 20 years of age). Bank clearings in 1927 aggregated $223,700,000.

Reading was founded in 1748 by Thomas and Richard, sons of William Penn, and was named after the county-town of Berkshire, England. It was incorporated as a borough in 1783, as a city in 1847. Though there were many Germans among the first set-

tlers, the control of local affairs remained in the hands of the English colonists until the outbreak of the Revolutionary War, after which, as the English were largely Loyalists, it passed to the Germans. In the French and Indian Wars Reading became a military base for a chain of forts along the Blue mountains. During the Revolution it was a depot of military supplies, and was the site of a prison camp in which the Hessians taken at the battle of Trenton were detained. This region was one of the first in America to manufacture iron and iron products. Cannon for use in the Revolution were made here, and Reading supplied much of the heavy ordnance used by the Northern Army in the Civil War. The first cooking stove made in America was cast in the Hereford furnace, 20 m. E. of the city, in 1767. The industrial development of the town was greatly stimulated by the opening of the Schuylkill canal to Philadelphia in 1824 (abandoned in 1922), the Union canal to Lebanon and Middletown in 1828 (abandoned about 1880), and the Philadelphia and Reading railway in 1838. A company of Reading and Berks militiamen was the first unit to report to Gen. Washington at Cambridge in response to the call for troops by the Second Continental Congress; and the Ringgold light artillery (later known as "the First Defenders"), largely recruited from Reading and Berks county, was the first volunteer company to reach the national capital when Lincoln called for troops.

READING COMPANY, a corporation operating or controlling 2,253 m. of railroad in the States of Pennsylvania, New Jersey and Delaware, which became a common carrier through merger on Dec. 31, 1923, of Reading Company (incorporated May 24, 1871), Philadelphia and Reading Railway Company (successor to The Philadelphia and Reading Railroad Company—incorporated April 4, 1833), and 12 other railroad companies theretofore forming part of the Reading system. Actual operations on some of its subsidiary lines began, however, as early as 1831, and a portion of its railroad was constructed under a charter granted Sept. 29, 1791. On Dec. 31, 1927, it had total assets of $434,367,562. It then owned 1,047 locomotives, 945 passenger cars, 43,719 freight cars, 760 work cars and 141 vessels. It maintains at Port Richmond, Philadelphia, the most extensive freight terminal in the world under one management, including a 2,500,000 bu. capacity modern concrete export grain elevator. It controls among other corporations the Central Railroad of New Jersey, Atlantic City railroad, Port Reading railroad and Perkiomen railroad, and furnishes terminal facilities at tide water for the trunk line systems having eastern connections. Its total gross receipts in 1927 were $105,495,655, excluding receipts of controlled companies. Of its operating revenues 43·6% were derived from the transportation of merchandise, 41·3% from anthracite and bituminous coal and 15·1% from passengers, mail and other sources. (A. T. D.)

READYMONEY, SIR COWASJI JEHANGIR (1812–1878), "the Peabody of Bombay," belonged to a family descended from Parsee merchants of the early 18th century who had adopted their nickname of "Readymoney" as a surname. At the age of 15 he entered the firm of Duncan, Gibb & Co. as "godown keeper," or warehouse clerk. In 1846 he began trading on his own account. He was made a J.P. for the town and island of Bombay, and a member of the board of conservancy, and in 1866 was appointed a commissioner of income tax. He was made C.S.I. in 1871, and in 1872 K.B. His donations to the institutions of Bombay amounted to close on £200,000.

See J. Cowasji Jehangir, *Sir Cowasji Jehangir Readymoney* (1890).

REAGAN, JOHN HENNINGER (1818–1905), American politician, was born in Sevier county, Tennessee, on Oct. 8, 1818. He removed to Texas in 1839, was admitted to the bar in 1846, and in 1857–61 was a representative in Congress. His political views were determined by the ultra-democratic influence of Andrew Jackson and the state-sovereignty philosophy of John C. Calhoun. In 1861 he was appointed postmaster general in President Davis's cabinet, and served in this capacity throughout the war. He was captured with the Davis party on May 10, 1865, and was imprisoned in Ft. Warren, Boston Harbour, until the following October. While in prison he wrote the "Fort Warren letter" (Aug. 11), in which he urged the people of Texas to recognize their defeat, grant civil rights to the freedmen, and try to conciliate the North. From 1875 to 1887, when he entered the U.S. Senate, he was again a representative in Congress. In 1891, believing that his first duty was to his State, he resigned from the Senate to accept the chairmanship of the newly established State railway commission. In 1901 he retired from public service. He died at Palestine, Tex., on March 6, 1905.

See his *Memoirs; with Special Reference to Secession and the Civil War* (1906), edited by W. F. McCaleb.

REALGAR, a mineral species consisting of arsenic monosulphide, AsS, and occurring as monoclinic crystals of a bright red colour. There is a perfect cleavage parallel to the plane of symmetry; hardness is 1·5–2, specific gravity 3·55. On exposure to light the crystals crumble to a yellow powder. The mineral usually occurs with ores of silver and lead in mineral veins. Realgar has been used as a pigment and in pyrotechny for producing a brilliant white fire; but it is now replaced by the artificially prepared compound. The other native arsenic sulphide, As_2S_3, is known as Orpiment (*q.v.*). (L. J. S.)

REALISM, a philosophical term used in two opposite senses. The older of these is the scholastic doctrine that universals have a more "real" existence than things. Universals are, in scholastic language, *ante res, in rebus* and *post res.* In the most extreme form realism denies that anything exists in any sense except universals. It is opposed to nominalism (*q.v.*) and conceptualism (*q.v.*). For the history of the doctrine, *see* SCHOLASTICISM. In this sense, realism has been called "an assertion of the rights of the subject," and some part of the teaching of Socrates concerns itself with the scholastic doctrine of realism. The modern application of the term is to the opposing doctrine that there is a reality apart from its presentation to consciousness. In this sense it is opposed to idealism (*q.v.*), whether the purely subjective or that more comprehensive idealism which makes subject and object mutually interdependent. In its crude form it is known as "Natural" or "Naïve" Realism. It appears, however, in more complex forms, *e.g.*, as Ideal Realism (or Real Idealism), which combines epistemological idealism with realism in metaphysics. Again, Kant distinguishes "empirical" realism, which maintains the existence of things in space independent of consciousness, from "transcendental" realism, which ascribes absolute reality to time and space. (*See* PHILOSOPHY, HISTORY OF.)

In literature and art "realism" again is opposed to "idealism" in various senses. The realist is (1) he who deliberately declines to select his subjects from the beautiful or harmonious, and, more especially, describes ugly things and brings out details of an unsavoury sort; (2) he who deals with individuals, not types; (3) most properly, he who strives to represent the facts exactly as they are.

REALITY: *see* LOGIC; ONTOLOGY.

REAL PRESENCE: *see* TRANSUBSTANTIATION and EUCHARIST.

REAL PROPERTY AND CONVEYANCING: *see* LAWS OF REAL PROPERTY AND CONVEYANCING.

REAPING, the action of cutting ripe grain crops. Till the invention of the reaping machine, which came into practical use only about the middle of the 19th century, sickles and scythes were the sole reaping implements. Of the two the sickle is the more ancient, and indeed there is some reason to conclude that its use is coeval with the cultivation of grain crops. Among the remains of the later Stone period in Great Britain and on the European continent curved flint knives have occasionally been found, the form of which has led to the suggestion that they were used as sickles. Sickles of bronze occur quite commonly among remains of the early inhabitants of Europe. Some of these are deeply curved hooks, flat on the under side, and with a strengthening ridge or back on the upper surface, while others are small curved knives, in form like the ordinary hedge-bill. Among the ancient Egyptians toothed or serrated sickles of both bronze and iron were used. Ancient Roman drawings show that both the scythe and the sickle were known to that people, and Pliny makes the distinction plain. (*Hist. Nat.* xviii. 67.) Although both implements have lost much of their importance since the general intro-

duction of mowing and reaping machinery, they are still used very extensively, especially in those countries like France where small agricultural holdings prevail. The principal modern forms are the toothed hook, the scythe hook, the Hainault scythe and the common scythe.

It was not until the beginning of the 19th century that any attempt was made to invent a reaping machine on anything like the lines that have been adopted since. In 1826 the Rev. Patrick Bell of Carmylie in Fifeshire brought out the first successful machine. He had worked at the making of it when a young man on his father's farm, and the principle he adopted, that of a series of scissors fastened on the "knife-board," was followed for a long time.

McCormick's Reaper, 1831.—After many modifications, however, the common reaper was evolved by C. H. McCormick in America in 1831. A truck or carriage is carried on two travelling wheels some 30 to 36 in. high, with spuds or teeth on the circumference to make them "bite" the ground and thus give motion to the machinery without skidding; two horses are yoked in front with a pole between, with martingale and surcingle belts as part of their harness, to ease the backing of the machine by the horses; the knife-board is fixed out at right angles to the side of the carriage and in front, while the knives consist of a series of triangular "sections" on a bar which travels backwards and forwards in slots in the "fingers," as the dividing teeth are called. The motion is given to the knives by a connecting rod and crank driven by suitable gearing from the truck wheels. The cutting is thus done by a straight shearing action and not by clipping like scissors as in Bell's machine.

In the early days—from about 1860 to 1870—machines were fitted with a tilting board behind the cutting bar which caught the corn as it fell, and it was held there until enough for a sheaf was gathered, when the load was "tilted" off by a suitable rake handled by a man who sat and worked the tilting board simultaneously with his foot and dropped the corn, to be lifted and tied into a sheaf by hand afterwards. The same machine was generally used for mowing (grass) by an interchange of parts, and the "combined" reaper and mower was in common use in the '70s and '80s. Later, various devices were adopted to do the tilting or sheafing mechanically, and the self end-delivery and self side-delivery were long in use whereby through the adoption of revolving rakes on frames the sheaf-lots were delivered in sizes ready for tying up by hand. The subsequent tying or binding was done variously in different parts of the country. In the south of England it was customary for five men to make bands, lift the sheaf-lot, place in the band and tie and leave the sheaf lying on the ground to be set up afterwards, the gang of five being expected to keep up to a reaper cutting round the four sides of a field. In the north and in Scotland the cutting was only done on one side at a time, the machine riding back empty, and three boys made the bands ("straps"), three women lifted the lots and laid them on the bands and three men bound the sheaves and set up in stooks. Thus three gangs of three each were required to keep a machine going, but only about five acres per day could be reaped.

The development of the modern binder to reduce all this labour has been a very gradual process. There was no great difficulty in cutting the corn and delivering the stuff, but the tying of it into sheaves was the problem to be solved. As early as 1858 Marsh in America designed and carried out an arrangement whereby the cut grain crop was caught on revolving webs of canvas and carried up on to a table, where two men stood who made bands of its own material and bound it into sheaves as it fell in front of them, dropping the sheaves off on to the ground as made, while the machine travelled along. The invention of a tying apparatus was the next advance, and in the 'seventies the American firm of Walter A. Wood & Co. brought out an arrangement for tying the sheaves up with wire. So slow and expensive had been the process of evolution, however, that it was reported at the time that the above firm had spent £20,000 in invention and experiment before they had even a wire-binder fit to put on the market.

The String Binder.—Binding with string, however, was the aim of all, and it was reserved for J. F. Appleby, an English inventor, to hit on the arrangement now in use, or which was the prototype of all the "knotters" now to be met with in different varieties of the string-binder throughout the world.

While the string-binder is now in universal use in Great Britain, the British Colonies, America and all countries where farming and farm work are advanced, and hand labour is only followed where peasant-farming or small farming obtains, it must be noted that in certain regions the system of reaping or harvesting of corn crops has developed a good deal beyond this. In Australia and some of the hotter districts in the west of the United States the "stripper" is in use, an implement which carries long grooved teeth which are passed through the standing grain crop and strip off the heads, leaving the straw standing. The heads are passed backwards to a thrashing (rubbing) arrangement, which separates the corn from the cobs, chaff, etc., and the grain is sacked up straight away. The sacks are dropped off the machine as the work proceeds and are picked up by wagon for transport afterwards. It is a significant fact that strippers worked by hand, though pushed through the crop by oxen, were in use on the plains of Gaul in the first century of our era, though this system seems to have been lost sight of till re-invented by the Australians.

Again, in the Western states of America, where the climate is not hot and dry enough for stripping purposes, the method followed is to cut the straw as short as possible—just below the heads—and these fall on to a travelling canvas and are carried up into a thrasher and the grain separated and sacked as the work proceeds. An immense combined implement is used for this reaping and thrashing purpose, taking a width of up to 40 ft. of crop at a time, and being propelled by a 50-horse-power traction engine running on broad roller-wheels, though smaller machines of, say, 20 horse-power are also common. Sometimes the "heading" only is carried out, and the cut heads carried on a canvas up into a wagon travelling alongside, and then carted away for subsequent thrashing, the "header" thus being the form of reaper adopted also in the Western states of America. Indeed this form of harvesting is now being introduced into the middle States, wherever the weather and the grain are dry enough to enable the latter to be stored in bulk straight away. It has even been suggested that it might be tried in Great Britain, but the climate would make it necessary to kiln-dry the grain before it could be stored in granaries, while the straw of all kinds is valuable for feeding and littering live stock. In those western regions, as in many other places on the prairies in general, the straw is of no value, and therefore the whole is set fire to and burned off, thus returning a certain amount of fertility to the soil in the ashes.

In the normal and ordinary system of reaping with the string-binder in Great Britain the rule is to "open up" a field by cutting "roads" round it: that is, a headland or roadway is mowed by the scythe and tied up by hand. Then the string-binder is started to cut around and continued till a finish is made at the centre of the field. Sometimes the crop is partly lodged and can only be cut on three sides of the field, and the binder is "slipped" past the fourth side. It is customary in some parts to yoke three horses to the machine and keep these at work all day with an interval for the midday meal only, but a better plan is to allow two men and four horses to each, and put one couple on and one couple off for meals and resting alternately. By this means the binder is kept going continuously without any stoppage for perhaps 14 hours daily in fine harvest weather. With a six-feet cutting width an acre per hour is fair work, but some have exceeded that, especially with wider cutting widths. A ball of twine weighing 3 to 4 lb. is the usual requisite per acre for binding the sheaves, and it ought to be of Manila hemp.

The sheaves are dropped off on to the ground as tied, but some farmers use the "sheaf-carrier," which catches these as they are shot out from the binding apparatus, and dumps them in lots of six or so—sufficient to make a stook or shock. The stooking—that is, the setting up of the sheaves on end to dry—is a separate operation, and from two to three men can set up an ordinary good crop as fast as the binder can cut it. In this work the sheaves are set with their butts wide apart and the heads leaning against one another like the two legs of the letter A: a full-sized stook or

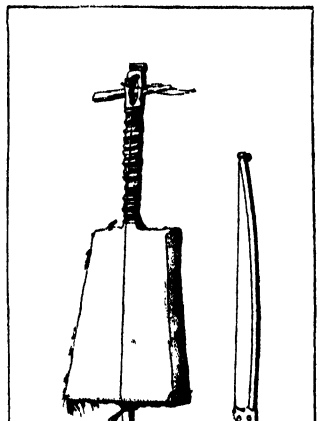
"threave" is 24 sheaves—a relic of the days when the crop was all hand-reaped by piecework at so much per threave—but in practice now seldom more than 6 sheaves (3 each side) are put to each stook. When sufficiently dried or "fielded" the sheaves are then carried by cart or wagon to the stackyard, where they are built up sheaf by sheaf into round or oblong stacks or sheds: that is, they are stored until required for thrashing and foddering purposes. The drying may be a tedious affair, and wet weather in harvest time may be a national disaster from the spoiling of the corn, both in grain and straw.

The tremendous development in labour-saving in the matter of reaping the corn crops is well exemplified in a comparison of harvesting with the hand hook or sickle as compared with the string-binder. With hand-reaping six men (or women) cut the corn and laid it on the bands in sheaf-lots: one man came behind and tied the sheaves and set them up in stooks. Thus a gang of seven worked together and harvested about two acres per day. With the binder three or four men handle say twelve or fourteen acres daily; in other words, there is only one-tenth of the manual labour required now in reaping that was necessary fifty years ago, for harvesting machinery has revolutionized farming as a whole, and given the nations cheap bread. (P. McC.)

See also HARVESTING MACHINERY.

REAR VAULT, in architecture, a vault supporting the thickness of the wall inside a window or door opening, usually with a splayed or sloped surface, and often laid out upon a different curve from that of the arch over the window or door itself. In Gothic architecture, especially in England, the rear vault is usually decorated at its inner edge by a projecting rib known as a scoinson rib, which is itself often supported by colonnettes known as scoinson shafts, at the inner edges of the opening.

REASON, in philosophy, the faculty or process of drawing logical inferences. Thus we speak of man as essentially a rational animal, it being implied that man differs from all other animals in that he can consciously draw inferences from premises. It is, however, exceedingly difficult in this respect to draw an absolute distinction between men and animals, observation of which undoubtedly suggests that the latter have a certain power of making inferences. Between the higher animals and the lower types of mankind the distinction is so hard to draw that many psychologists argue that the difference is one of degree rather than of kind (*see* also INSTINCT). There can be little doubt, however, that inference by man differs from that of the brute creation in respect of self-consciousness, and, though there can be no doubt that some animals dream, it is difficult to find evidence for the presence of ideas in the minds of the lower animals. In the nature of the case satisfactory conclusions as to the rationality which may be predicated of animals are impossible.



The term "reason" is also used in several narrower senses. Thus reason is opposed to sensation, perception, feeling, desire, as the faculty (the existence of which is denied by empiricists) by which fundamental truths are intuitively apprehended. These fundamental truths are the causes or "reasons" (*ἀρχαί*) of all derivative facts. With Kant, reason (*Vernunft*) is the power of synthesizing into unity, by means of comprehensive principles, the concepts provided by the intellect (*Verstand*). The reason which gives *a priori* principles Kant calls "Pure Reason," as distinguished from the "Practical Reason" which is specially concerned with the performance of actions. In formal logic the drawing of inferences (frequently called "ratiocination," from Lat. *ratiocinari*, to use the reasoning faculty) is classified from Aristotle downwards as deductive (from generals to particulars) and inductive (from particulars to generals); *see* LOGIC, INDUCTION, SYLLOGISM. In theology, reason, as distinguished from faith, is the human intelligence exercised upon religious truth whether by way of discovery or by way of explanation. The limits within which the reason may be used have been laid down differently in different churches and periods of thought: on the whole, modern Christianity, especially in the Protestant churches, tends to allow to reason a wide field, reserving, however, as the sphere of faith the ultimate (supernatural) truths of theology.

The Greek words for reason are *νοῦς* and *λόγος*, both vaguely used. In Aristotle the *λόγος* of a thing is its definition, including its formal cause, while the ultimate principles of a science are *ἀρχαί*, the "reasons" (in a common modern sense) which explain all its particular facts. *Νοῦς* in Plato and Aristotle is used both widely for all the meanings which "reason" can have, and strictly for the faculty which apprehends intuitively. Thus, in the *Republic*, *νοῦς* is the faculty which apprehends necessary truth, while *δόξα* (opinion) is concerned with phenomena.

The Schoolmen distinguished between *ratio cognoscendi* (a reason for acknowledging a fact) and *ratio essendi* (a reason for the existence of this fact).

RÉAUMUR, RENÉ ANTOINE FERCHAULT DE (1683–1757), French scientist, was born on Feb. 28, 1683, at La Rochelle, where he received his early education. In 1703 he came to Paris, where he continued the study of mathematics and physics, and in 1708 was elected a member of the Académie des Sciences. In 1710 he was charged with the official description of the useful arts and manufactures of France, which led him to many practical researches that resulted in the establishment of new manufactures and the revival of neglected industries. For discoveries regarding iron and steel he was awarded a pension of 12,000 livres; but he requested that the money should be secured to the Académie des Sciences for the furtherance of experiments on improved industrial processes. In 1735 family arrangements obliged him to accept the post of commander and intendant of the royal and military order of Saint-Louis; he discharged his duties with scrupulous attention, but declined the emoluments. Réaumur died at La Bermondière, Maine, on Oct. 17, 1757. He bequeathed his manuscripts, which filled 138 portfolios, and his natural history collections to the Académie des Sciences.

Réaumur's papers deal with nearly all branches of science. He examined and reported on the auriferous rivers, the turquoise mines, the forests and the fossil beds of France. He devised the method of tinning iron that is still employed, and investigated the chemical differences between iron and steel. His book on this subject (1722) was translated into English and German. The thermometric scale by which he is now best remembered was constructed on the principle of taking the freezing-point of water as 0°, and graduating the tube of the thermometer into degrees each of which was one-thousandth of the volume contained by the bulb and tube up to the zero mark. It was an accident dependent on the coefficient of expansion of the particular quality of alcohol employed which made the boiling-point of water 80° C; and mercurial thermometers the stems of which are graduated into eighty equal parts between the freezing- and boiling-points of water are Réaumur thermometers in name only. Réaumur wrote widely on natural history, his best known work on this subject being the *Mémoires pour servir à l'histoire des insectes* (6 vols., 1734–42).

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

AN ARABIAN REBAB AND BOW

REBAB or **RABAB,** an ancient stringed instrument, sometimes plucked and sometimes played with a bow, having a body either pear-shaped or boat-shaped and the characteristics of vaulted back and the absence of neck; also a generic modern Arabic term applied by the Mohammedans of northern Africa to various stringed instruments played with a bow. The rebab exercised a very considerable influence on the history of stringed instruments in Europe, and was undoubtedly the means through which the bow was introduced to the West, though whether it may be accepted as the ancestor of the violin, as is held by some, is another matter.

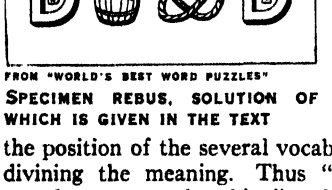
The bowed instruments of the middle ages fall naturally into

two distinct classes, according to the principles observed in construction. One is the type having a body formed on the model of a Greek or a Roman cithara, with back and sound board connected by ribs, from which it was evolved by the addition of a neck and finger-board (*see* GUITAR and GUITAR-FIDDLE). The other is the type derived from the Eastern rebab, with vaulted back attached directly to the sound board, which has never attained to any serious artistic development.

For the European development of the rebab, *see* REBEC.

REBATES, DEFERRED. A deferred rebate is a discount on the invoice price returned after a lapse of time to a trader, on certain conditions, as a means of maintaining monopoly and keeping out would-be competitors from the trade. The system is in use in many branches of British trade and industry. It consists in returning to the trader (merchant or retailer) at the end of every six or 12 months a rebate equal to perhaps 10 or 15% on his purchases, on condition that he shall not, during the period, have sold, displayed (or, it may be, offered) any of the kind of goods produced by the combination except those made by the combination. The effect of the arrangement is that if at any time during that period the customer is offered an article of better value by an outside maker or by a new firm starting in the industry, the buying of that article will cost him anything from one to 12 months' accumulated rebates on his association purchases and may result in his being placed on the association's "black list," which means that he shall not again be supplied with association goods except at prices which will yield an insufficient profit on resale. The reasons advanced by combinations for the use of the deferred rebate are not altogether reasons of monopoly. They contend that steadiness and continuity of custom are essential to economical manufacture; that by maintaining an even level of prices (which, as the market fluctuates, may be temporarily under-profitable as sometimes over-profitable) they are serving the best interest of the customer; and that these mutual advantages cannot be secured if the customer is left free to trade with the combination when its prices are below average, and go elsewhere when they are above. The most notable example of the use of the deferred rebate is to be found in the case of the shipping companies operating liner services, where the fluctuating competition of the "tramp" and the great importance of securing a steady volume of freights if a regular service is to be maintained lend particular weight to the arguments quoted above. In the manufacturing industries there is less agreement among members of combinations as to the advantage of the deferred rebate, and instances have occurred of the system being voluntarily abandoned. (J. H.)

REBEC or **REBECK,** a mediaeval stringed instrument played with a bow, derived from the Oriental rebab, and sometimes regarded as the ancestor of the viol and violin. Like the rebab (*q.v.*), the rebec assumed at first one of two forms—the pear-shaped body with a wide base, strung with three strings, or the long, narrow pear- or boat-shaped body with two strings and, in addition, the other Oriental characteristics of the rebab, *i.e.*, the vaulted back, the absence of ribs, and pegs set in the back of the head. Except for the addition of a fingerboard, what is now recognized as the rebec underwent no structural development and never entered the domain of art, despite the wide favour which it enjoyed throughout the middle ages.



REBECCA RIOTS, the name given to some disturbances which occurred in 1843 in South Wales. The rioting was directed against the charges at the toll-gates on the public roads, and the rioters took as their motto the words in Gen. xxiv. 60, "And they blessed Rebekah, and said unto her, Thou art our sister, be thou the mother of thousands of millions, and let thy seed possess the gate of those which hate them." Many of the rioters were disguised as women and were on horseback; each band was led by a captain called "Rebecca," his followers being known as "her daughters." They destroyed not only the gates but also the toll-houses, the work being carried out suddenly and at night, but usually without violence to the toll-keepers, who were allowed to depart with their belongings. Emboldened by success, the Rebeccaites turned their attention to other grievances. The government despatched soldiers and police to south Wales, and the disorder was quelled. South Wales was relieved from the burden of toll-gates, while the few rioters who were captured were only lightly punished. The movement was separate from Chartism (*q.v.*), but was supported by the same class and arose from the same economic causes.

REBELLION, the act of one who engages in armed resistance to the government to which he owes allegiance. For instance the supporters of the Old Pretender in 1715 and of the Young Pretender in 1745 were regarded and punished as rebels. In the American Civil War of secession, the Federal Government continued for two years to regard the Confederates as rebels although they had been recognized as belligerents by neutral states. And in the South African War of 1899–1902 it was held by the Supreme Court of the Cape of Good Hope that rebels who joined the Burgher forces, and thus committed high treason, remained liable to be punished for criminal offences, although the Burghers had been recognized as belligerents; *Rex* v. *Louw* 21 C. G. H. Supreme Court Rep. 36 (1905). *See* LAWS OF WAR.

REBIKOV, VLADIMIR (1866–), Russian composer, was born at Krasnoyarsk in 1866, and studied in Moscow, Berlin and Vienna. He then went to live at Odessa, where, in 1894, his first opera, *The Thunderstorm,* was produced. Other dramatic works are *The Christmas Tree* (1903), *Narcissus, The Fables of Krylov* (his best-known work); *Prince Charming,* a fairy opera, and the pantomime *Snow-White* (1909). He has also written suites for pianoforte, including the *Mélomimiques,* and mimetic vocal pieces. His music makes no appeal to the popular mind, and is difficult to grasp on account of its harshness and lack of form. Rebikov's literary work includes a translation of Gevaert's *Traité d'Instrumentation* (1899) and *La musique de 1960.*

REBOUX, PAUL (1877–), French novelist and man of letters, was born in Paris on May 21, 1877, and educated at the *école Fénélon* and under private tuition. He became editor of *La Charrette* and dramatic critic of the *Journal du Peuple* and then literary director of *Le Journal.* He has used many different countries for the background of his novels, Spain, Italy and Brittany. To the literature of war he has contributed a novel in two volumes, *Les Drapeaux* (1921), directed against militarism, of which Lalou says that it attempts "to annex to the novel the science of statistics." One of the most read and most amusing of his works is *A la manière de . . .*, a series of parodies on well known writers.

REBUS, a sort of riddle consisting of the representation of some sentence or thing by means of pictures or words, or a combination of both. Rebuses first became popular in France, where they were at first called *rébus de Picardie,* that province, according to G. Ménage (1613–92), having been the scene of their origin. Camden mentions an instance of this kind of wit in a gallant who expressed his love to a woman named Rose Hill by painting in the border of his gown a rose, a hill, an eye, a loaf, and a well; this, in the style of the rebus, reads "Rose Hill I love well." A specimen of a modern rebus is given here, the solution of which is: "Be independent but not too independent" (B in D pendant, butt knot 2 in D pendant).

FROM "WORLD'S BEST WORD PUZZLES"

SPECIMEN REBUS, SOLUTION OF WHICH IS GIVEN IN THE TEXT

The name is also applied to arrangements of words in which the position of the several vocables is to be taken into account in divining the meaning. Thus "I understand you undertake to overthrow my undertaking" makes the rebus

Stand take to taking
I you throw my.

A simple French rebus is expressed by the two letters G a, which may be read, *J'ai grand appétit* (*G grand, a petit*).

"Rebus" (or "allusive arms"), in heraldry (*q.v.*), is a coat of arms which bears an allusion to the name of the person—as three castles for Castleton, three cups for Butler.

Ben Jonson happily ridiculed this kind of wit in his description of Abel Drugger's device in the *Alchemist.*

RECALL, a device by which the voters may remove an official from office before the expiration of his regular term. It is based upon the principle that officials are properly mere agents of the popular will, and as such should be constantly subject to their control. Under the plan, if a specified percentage of the electorate are dissatisfied with an official's conduct and sign a petition for his removal, the officer must face a general election to determine the majority opinion.

Like the initiative and referendum the recall originated in Switzerland where it is applicable not only to individuals but to the entire legislature. In the United States where its widest use is now found, it first appeared in 1903 in the city charter of Los Angeles. It was soon adopted by many cities with the commission form of government as the most effective way to control the commissioners into whose hands such large powers were put. It was first adopted with State-wide application in Oregon in 1908, followed by California in 1911, Arizona, Idaho, Washington, Colorado and Nevada in 1912, Michigan in 1913, Louisiana, North Dakota and Kansas in 1914. Most of these were States with a large number of elective officers, who, since they were not subject to removal by the governor, were, in effect, beyond control during their term of office. In one State, Kansas, the recall extends to appointed as well as elected officials. In four of the eleven, Idaho, Louisiana, Michigan and Washington, it is not applicable to judges on the ground that the judiciary should be independent of popular passions and political issues.

Though the general principle of the recall is simple, there are many variations in its practical application, which considerably alter its effect. For instance under some plans the question of removal may be decided in one election, and the question of a successor in a subsequent election. For economy's sake the two are often combined into one election in which the official whose conduct is under question may stand as a candidate if he desires. In the latter case the question of his record is evidently complicated by the element of his comparative popularity. The vote required to remove an official may be a simple majority or a higher percentage. The percentage of signatures required to force an election ranges widely, the average being about 25%; and the methods by which it is permissible to secure signatures may vary sufficiently to affect the result. The recall has, in fact, been but seldom resorted to and then almost entirely for local officers. Only twice has it found State application, notably in North Dakota in 1921 when the governor, attorney-general and commissioner of agriculture were removed. Only a few instances of its being applied to judges are on record, all of them in minor courts. In its State-wide application it becomes too cumbersome to be frequently resorted to. Its chief value is perhaps not to be measured by the frequency with which it is applied, but by the restraining influence which its existence may exercise.

See W. E. Rappard, "Initiative, Referendum and Recall in Switzerland," *Annals of the Amer. Acad. of Political and Social Science* (Sept. 1912); W. B. Munro, *The Initiative, Referendum and Recall* (1912); J. D. Barnett, *Operation of the Initiative, Referendum and Recall in Oregon* (1915). The argument against the recall of judges is presented by W. H. Taft in his veto of the enabling act for the admission of Arizona, whose Constitution allowed such a recall (*House Ex. Doc. No. 106,* 62nd Cong. 1st Sess.).

RÉCAMIER, JEANNE FRANÇOISE JULIE ADÉLAÏDE (1777–1849), a famous Frenchwoman in the literary and political circles of the early 19th century, was born on Dec. 4, 1777, at Lyons. Her maiden name was Bernard. She was married at fifteen to the banker Jacques Récamier (d. 1830), who was more than old enough to be her father. From the early days of the consulate to almost the end of the July monarchy her salon in Paris was one of the chief resorts of literary and political society that pretended to fashion. The *habitués* of her house included many former royalists, with others, such as Bernadotte and General Moreau, more or less disaffected to the government. Through her friend Madame de Staël, Madame Récamier became acquainted with Benjamin Constant (*q.v.*). She was eventually exiled from Paris by Napoleon's orders. After a short stay at Lyons she proceeded to Rome, and finally to Naples, where she was on good terms with Murat and his wife, who were then intriguing with the Bourbons. She persuaded Constant to plead the claims of Murat in a memorandum addressed to the congress of Vienna, and also induced him definitely to oppose Napoleon during the Hundred Days. Her husband had sustained heavy losses in 1805, and she visited Madame de Staël at Coppet in Switzerland. In her later days she lost most of the rest of her fortune; but she continued to receive visitors at the Abbaye-aux-Bois, the old Paris convent to which she retired in 1814. Here Chateaubriand was a constant visitor, and in a manner master of the house; but even in old age, ill-health and reduced circumstances Madame Récamier never lost her attraction. She numbered among her admirers Mathieu de Montmorency, Lucien Bonaparte, Prince Augustus of Prussia, Ballanche, J. J. Ampère and Constant, but none of them obtained over her so great an influence as did Chateaubriand, though she suffered much from his imperious temper. Her sincerest affection seems to have been for Prosper de Barante, whom she met at Coppet. She died in Paris on May 11, 1849.

There are well-known portraits of her by Louis David in the galleries of the Louvre, and by François Gérard in the possession of the préfecture of the Seine. In 1859 *Souvenirs et correspondances tirés des papiers de Madame Récamier,* was edited by Mme. Lenormant. *See* Mme. Lenormant's *Madame Récamier, les amis de sa jeunesse et sa correspondance intime* (1872); Mme. Mohl, *Madame Récamier,* with a sketch of the history of society in France (1829 and 1862); also Guizot in the *Revue des deux mondes* for December 1859 and February 1873; H. Noel Williams, *Madame Récamier and her Friends* (London, 1901); E. Herriot (Eng. trans., by Alys Hallard), *Madame Récamier et ses amis* (1904) (elaborate and exhaustive); L. de Launay, *Un amoureux de Madame Récamier; journal de J. J. Ampère* (1927).

RECANATI, a city of the Marches, Italy, in the province of Macerata, 8 m. direct N.N.E. of the city of that name. Pop. (1921) 15,309 (town); 15,787 (commune). It has a station on the railway 17½ m. S. of Ancona, and distant 4½ m. from the town, which is built on a hill, 931 ft. above the sea. It was the birthplace of the poet Leopardi (1798–1837). It possesses a Gothic cathedral, built towards the close of the 14th century and dedicated to S. Flavianus, patriarch of Constantinople. The churches of S. Maria dei Mercanti and San Domenico contain pictures by Lorenzo Lotto, as also does the municipal palace, with a fine old battlemented tower, while the palace of Cardinal Venier has a fine Renaissance portico by Giuliano da Maiano. The help given the popes in their struggles with the Sforza caused the decline of the city which suffered from an earthquake in 1741 and from wars (1797–99).

RECEIPT, in law, an acknowledgment in writing that a sum of money or other valuable consideration has been received by the person signing the acknowledgment in discharge of a debt or other obligation. Such a receipt is *prima facie* evidence of payment. By the Stamp Act of 1891 a duty of 1d. was imposed on every receipt or form of writing discharging a debt of £2 or upwards; the payment of the duty is denoted by affixing a stamp to the document, and the cancelling of the same by the person giving the receipt. By s. 103 if a person gives a receipt, liable to duty, not duly stamped, or refuses to give a receipt, liable to duty, duly stamped or, on payment to the amount of £2 or upward, gives a receipt for a less sum than £2 or divides the amount paid with intent to evade the duty, he is liable to a fine of £10. A receipt not duly stamped may be stamped at the Inland Revenue Office within 14 days on payment of a fine of £5 or within one month on payment of £10. By the Finance Act of 1920 the receipt stamp was increased to 2d.

American Law.—There are no stamp duties on receipts in the United States. On the effect of a receipt in full, given against payment of less than the amount due, see *Discharge.* On receipts for goods given by transportation or storage agencies see *Bill of Lading, Warehouse Receipt.* The commercial practice of a debtor requiring a receipt on paying a debt has, curiously, no warrant in law except in particular cases: a debtor paying a negotiable instrument (*see* BILL OF EXCHANGE) is entitled to have it surrendered to him, which serves as a receipt; and a mortgagor paying off a mortgage is entitled to receive from the mortgagee a "satisfaction piece" which serves as evidence that the obligation and the mortgage are discharged. In other cases,

in general, the debtor's assurance of procuring a receipt rests partly on business custom, partly on the creditor's practical desire to collect his debt and on his willingness to accept payment by check, which will then serve as a receipt.

RECEIVER, in English and American law, a person appointed by a court to administer property for its protection, to receive rent or other income and to pay authorized outgoings. Receivers may be either appointed *pendente lite* or by way of equitable execution, *e.g.*, for the purpose of enabling a judgment creditor to obtain payment of his debt, when the position of the real estate is such that ordinary execution will not reach it. Formerly receivers were appointed only by the court of chancery, but by the Judicature Act of 1873 it is now within the power of all divisions of the High Court to appoint receivers. Their powers and their duties are set forth by Kerr, *On Receivers* (5th ed., 1905), who classifies the cases in which they may be appointed under the following heads: (*a*) infants; (*b*) executors and trustees; (*c*) pending litigation as to probate; (*d*) mortgagor and mortgagee; (*e*) debtor and creditor; (*f*) public companies; (*g*) vendor and purchaser; (*h*) covenanter and covenantee; (*i*) tenant for life and remainderman; (*j*) partners; (*k*) lunacy; (*l*) tenants in common; (*m*) possession under legal title, and (*n*) other cases. The appointment of receivers is entirely within the discretion of the courts. In bankruptcy practice a receiver, termed official receiver, is an officer of the court who in this capacity takes possession of all a debtor's assets. In the United States the appointment of receivers lies within the jurisdiction of courts that are invested with equity powers and in exercise of their equity jurisdiction. Under statutes in many States the power to appoint receivers has been extended to actions at law in various types of cases. (*See* BANKRUPTCY.)

RECEIVING: *see* LARCENY.

RECEIVING SET, the equipment that reproduces speech, music, visible messages or signals from radio waves. (*See* RADIO RECEIVER.)

RECHABITES or **SONS OF RECHAB,** a sort of religious order among the Israelites, analogous to the NAZARITES (*q.v.*), with whom they shared the rule of abstinence from wine. They eschewed settled life, and lived in tents, refusing to sow grain or plant vineyards. They represented a protest against the contemporary civilization and a reaction towards simplicity of life. Their "father," or founder, was that Jehonadab (or Jonadab) son of Rechab, who encouraged Jehu to abolish the Tyrian Baal-worship (2 Kings x.). The "house of Rechab" fled for protection into Jerusalem at the approach of Nebuchadrezzar (Jer. xxxv.), and Jeremiah promised them, as a reward of their adherence to the ordinance of Jehonadab, that they should never lack a man to represent them (as a priest) before Yahweh. Later Jewish tradition states that the Rechabites intermarried with the Levites.

RECHBERG-ROTHENLÖWEN, JOHANN BERNHARD, COUNT (1806–1899), Austrian statesman, was the second son of the Bavarian statesman Count Aloys von Rechberg-Rothenlöwen (1766–1849). Johann Bernhard was destined for the Bavarian public service, and he was educated at the universities of Strasbourg and Munich, but incurred the displeasure of King Louis I. by the part he played as second in a duel, and in 1828 transferred to the Austrian diplomatic service. After being attached to the embassies in Berlin, London and Brussels, he was appointed envoy at Stockholm (1841) and at Rio de Janiero (1843). Returning to Europe in 1847, on the outbreak of the revolution of 1848 in Vienna he accompanied and assisted Prince Metternich in his flight to England. In July 1848 he was appointed Austrian plenipotentiary in the German federal diet at Frankfort, and in 1851 became Austrian *internuncius* at Constantinople, and in 1853 Radetzky's civilian colleague in the government of Lombardo-Venetia. In 1855 he returned to Frankfort as Austrian representative and president of the federal diet. Here his constant disputes with Bismarck, at that time Prussian envoy at the diet, were much sharpened by Rechberg's choleric temper, and on one occasion nearly led to a duel. Bismarck, however, always expressed a high appreciation of his character and abilities. In May 1859, on the eve of the war with Italy, he was appointed Austrian minister of foreign affairs and minister president, surrendering the latter post to the archduke Rainer next year.

The five years during which Rechberg held the portfolio of foreign affairs covered the war with Italy and France, the insurrection in Poland, the attempted reform of the German Confederation through the Frankfort *Fürstentag*, and the Austro-Prussian war with Denmark. Their story is told elsewhere. (*See* EUROPE and AUSTRIA.) In the German question Rechberg's policy was one of compromise, and he generally advocated peaceful arrangement between Prussia and Austria as the indispensable preliminary to a reform of the Confederation. In the Schleswig-Holstein question he was, however, consistently outwitted by Bismarck, and signed on Oct. 27, 1864. Rechberg resigned. He received the Golden Fleece from the emperor as a sign of special favour. He had been made an hereditary member of the Upper House of the *Reichsrat* in 1861, and as late as 1879 continued occasionally to take part in debates. He died at his Kettenhof near Vienna on Feb. 26, 1899.

See the biography by Franz Ilwof in *Allgemeine Deutsche Biographie*, B. 53. *Nachträge* (Leipzig, 1907).

RECIDIVISM, a disposition or tendency to relapse into crime. While such a disposition may not be a matter of habit but the consequence of mental disorder or congenital defect, the term recidivist is, in criminology, usually employed interchangeably with "habitual offender" (*q.v.*).

RECIFE or **PERNAMBUCO,** a city and seaport of Brazil, capital of the State of Pernambuco, in 8° 3′ S. and 34° 55′ W., near the extreme eastern point of South America. Population (1920) 238,843. Recife is frequently called the "Venice of America"; it is at the mouths of the rivers Beberibe and Capibaribe which unite to form a small lagoon or bay inside the sea beach. In the angle between the two rivers is the delta island of Antonio Vaz. The city is built on the southern extremity of the sandy sea beach, on the island of Antonio Vaz, and on the mainland to the westward, the river channels being crossed by numerous bridges. With the exception of the hills on which Olinda is built about 5m. northward, the surrounding country is low and flat, the general elevation averaging 10 feet. As the tide rises about 6ft., the general level of the city and neighbouring coast, which is wet and swampy to the southward, is too low to be generally healthy. The climate is hot, although agreeably tempered by the south-east trade winds; the temperature ranges from an absolute minimum of 61° to an absolute maximum of 99°. The rainfall (1901 to 1919) is 74·8 inches. Federal, State and municipal governments, in co-operation with the Rockefeller Foundation (1919), the erection of modern hospitals, a new water system (1917) and the extension of sanitation, have improved health conditions. The death-rate has been reduced to about 34 per 1,000. Yellow fever and smallpox have been practically eradicated. Paving of old and narrow streets has advanced and in the newer parts of Recife wide modern avenues are extending. The three principal parishes of the city are known as São José do Recife, occupying the sandy peninsula or beach north of the outlet of the united rivers; Santo Antonio, on the island of Antonio Vaz, which was called Mauritia or Mauritzstad during the Dutch occupation; and Boa Vista, on the mainland to the westward, which is the most modern and the most rapidly growing part. The first is the oldest and most crowded section, and is now devoted chiefly to the commercial and financial interests of the port; here are the custom house, merchants' exchange (Praça do Commercio), shipping offices, banks and wholesale houses. Santo Antonio dates from the Dutch occupation. Prince Maurice of Nassau, when governor general, built here his private residence (Fribourg House) and made it his capital. Its business edifices and residences are largely Dutch architecture, with many storeys and steep roofs. The older part of Boa Vista dates from the 17th century. The older buildings are of the Portuguese type, usually plain, low and heavy, constructed of broken stone and mortar and plastered and coloured on the outside. Among new public buildings are fine municipal and State offices, a law college, a commercial museum, schools and theatres. New business buildings and private homes add to the city's attractiveness. Electric light and street car services have

extended further into the suburbs. Good roads are multiplying and the use of motor cars is growing.

The port of Recife is one of the most important of Brazil, on account of its proximity to Europe and its convenience for vessels passing around the east shoulder of the continent. It is the landing-place for one coastwise and two transatlantic cable lines. Its harbour consists of an outer and inner anchorage, the former an open roadstead, which are separated by a remarkable stone reef running parallel with the shore-line, leaving an inside passage 400 to 500ft. wide. The entrance to the inner anchorage, which has a depth of about 23ft., is opposite Ft. Brum in the northern part of the city, and is marked by a small Dutch fort (Picão) and a lighthouse at the northern extremity of the reef. This remarkable natural breakwater, which is about 50ft. wide on top and has been repaired with masonry in some places, covers a considerable part of the coast-line in this part of Brazil. It is not a coral reef, as is sometimes stated, but is a consolidated ancient beach, now as hard and firm as stone. Port construction, now well advanced, has already cost $20,000,000; additional construction is in progress, including a new light system (1925) and the deepening of the inner harbour. The exports include sugar, rum, cotton, lumber, hides, skins, rubber, wax, fibres, dyewoods, caucan, mandioca flour, pineapples and other fruits. The total commerce handled in a recent year amounted to 363,000 tons. More than 1,000m. of railways radiate to interior regions, providing outlet through Recife. Pernambuco is the principal sugar-producing State of Brazil, and Recife is therefore an important centre for this product. Its railway communications with the interior are good, and include the Sul de Pernambuco, Recife and São Francisco, Central de Pernambuco, and the Recife to Limoeiro lines, the first three now being under the management of the Great Western of Brazil Company. There are also suburban lines to Olinda and Caxangá, the latter providing communication with some of the prettiest suburbs about the city.

Recife was settled about 1535, when Duarte Coelho Pereira landed there to take possession of the captaincy granted him by the Portuguese crown. The site of Coelho's capital was Olinda, but Recife remained its port and did not become an independent villa (town) until 1710. Down to the close of the 18th century, when Rio de Janeiro became important, Recife was the second city of Brazil, and for a time its most important port. It was captured and plundered in 1595 by the English privateer James Lancaster. It was also captured by the Dutch in 1630 and remained in their possession till 1654, during which time the island of Antonio Vaz was occupied and the town greatly improved. At the end of the Dutch War the capital was removed from Olinda to Recife, where it has since remained.

RECIPROCATING ENGINE: *see* STEAM ENGINE.

RECIPROCITY, the condition or state of being reciprocal, *i.e.* where there is give and take, mutual influence, or correspondence between two parties, persons or things (Lat. *reciprocus*, returning back the same way, alternating, probably from *re* back and *pro* forward). In a more particular sense, reciprocity is a special arrangement between two nations under which the citizens of each obtain advantages or privileges in their trading relations with the other. This meaning of reciprocity, however, bears a different interpretation in European and in American usage. In the former, reciprocity between two nations usually means little more than the extension by one to the other of most favoured nation treatment, *i.e.* such advantages as it extends to any third country (*see* COMMERCIAL TREATIES). In the United States reciprocity is the term applied to the concessions or arrangements made between that country and another without reference to any third country. Thus in the United States there is a maximum and minimum tariff, the rates of the maximum tariff being enforced on the goods of those countries which have no reciprocity treaty with the United States, and the rates of the minimum on certain products of those countries which have by a reciprocity treaty given special advantages or concessions to certain products of the United States.

RECITATIVE: *see* MUSIC, section 5.

RECKLINGHAUSEN, a town in the Prussian province of Westphalia, 22 m. by rail N.W. of Dortmund. Pop. (1925) 114,813. The county of Recklinghausen belonged to the archbishopric of Cologne until 1803, when it passed to the duke of Arenberg. It was known as the West Recklinghausen. After 1815 the duke of Arenberg held it as a fief under Prussian sovereignty. In the neighbourhood of Recklinghausen are extensive coal-mines, iron and tin foundries and brick-works, and the industries embrace the manufacture of linen, beer, spirits, cement, soap and ammonia.

RECLAMATION OF LAND: *see* LAND RECLAMATION.

RECLUS, JEAN JACQUES ELISÉE (1830–1905), French geographer, was born at Sainte-Foy la Grande (Gironde), on March 15, 1830, the second son of a Protestant pastor. He was educated at the Protestant college of Montauban, and studied geography under Karl Ritter at the University of Berlin. Leaving France in December 1851, he spent six years (1852–57) visiting the British Isles, the United States, Central America, and Colombia. During the siege of Paris, Reclus shared in Nadar's aerostatic operations. He was taken prisoner on April 5, 1871, while serving in the National Guard, now in open revolt, and on Nov. 16 sentenced to transportation for life; but the sentence was commuted in Jan. 1872 to perpetual banishment. After a short visit to Italy, he settled at Clarens, in Switzerland, where he resumed his literary labours, and, after producing the *Histoire d'une montagne* (a companion to *Histoire d'un ruisseau*), wrote nearly the whole of his great work, *La Nouvelle Géographie universelle, la terre et les hommes,* 19 vols. (1875–94). This is a stupendous compilation, profusely illustrated with maps, plans and engravings, and was crowned with the gold medal of the Paris Geographical Society in 1892. An English edition appeared simultaneously, also in 19 vols., the first four by E. G. Ravenstein, the rest by A. H. Keane. Extreme accuracy and brilliant exposition form the leading characteristics of all Reclus's writings, which thus possess permanent literary and scientific value. In 1882 Reclus initiated the "Anti-Marriage Movement," in accordance with which he allowed his two daughters to marry without any civil or religious sanction. This resulted in government prosecutions, instituted in the High Court of Lyons, against the anarchists, members of the International Association, of which Reclus and Prince Kropotkin were designated as the two chief organizers. The prince was arrested and condemned to five years' imprisonment, but Reclus, being resident in Switzerland, escaped. In 1892 he became professor of comparative geography in the University of Brussels. Reclus died on July 4, 1905.

His works are: *Histoire d'un ruisseau* (1869); *La Terre: description des phénomènes de la vie du globe* (2 vols., 1867–1868); *Histoire d'une montagne* (1880); *La Nouvelle Geographie universelle, la terre et les hommes* (19 vols., 1875–1894); *L'Homme et la terre* (1905); and many contributions to scientific journals.

RECOGNIZANCE, a term of English law usually employed to describe an obligation of record, entered into before some court or magistrate duly authorized, whereby the party bound acknowledges that he owes a personal debt to the Crown, with a defeasance, *i.e.*, subject to a condition that the obligation to pay shall be avoided if he shall do some particular act—as if he shall appear at the assizes, keep the peace, or the like. Recognizances are now used almost solely with reference to criminal proceedings. The security given by a receiver appointed by the High Court is still in the form of a recognizance acknowledging a debt to named officers of the court, and securing it on the real and personal estate of the receiver.

There is a general jurisdiction on conviction of misdemeanour both at common law and by statute to put the offender under recognizances to keep the peace and (or) be of good behaviour in addition to or in substitution for other punishment. On refusal to enter into recognizances as above, the court may order imprisonment for the refusal, limited in cases within the Acts to 12 months, and in cases within the Act of 1879 to six months.

The recognizances above described may be described as a form of punishment or a judicial security for good conduct. Recognizances are, however, most used with reference to proceedings before conviction and judgment. In preliminary enquiries into indictable offences the enquiring justices take recognizances to

ensure the attendance of the accused if liberated during any adjournment, and on committal for trial take the recognizances of the accused (if allowed bail) to attend the court of trial and take his trial, and of the prosecutor and the witnesses for the prosecution or defence to attend and prosecute or give evidence. The recognizances taken are returnable under penalty to the court of trial, which orders their estreat (*q.v.*) in the event of breach of the conditions.

Similar powers as to the recognizances of persons prosecuted summarily are given by the Summary Jurisdiction Acts 1848 and 1879 as amended by the Criminal Justice Act 1925.

By the Land Charges Act 1925 a recognizance, whether obtained or entered into on behalf of the Crown or otherwise, does not operate as a charge on land or on any interest on land or on the unpaid purchase money for any land, unless a writ or order for the purpose of enforcing it is registered in the office of the Land Registry. This enactment is clearly applicable to receivers' recognizances; and on purchases of land search is made for registered recognizances and an official certificate can be obtained affirming or negativing the existence of a registered entry.

In the United States, the States allow by either common law or the statutes recognizances in much the same way as in England.

RECONNAISSANCE, a military term denoting the reconnoitring or examination of an enemy's position or movements. A topographical reconnaissance is a survey of a tract of country or route, comprising both a map and a report as to its advantages and disadvantages. All reconnoitring work of this character is done by officers with small patrols, escorts or assistants. Strategical reconnaissance was formerly carried out by cavalry formations or units down to squadrons, according to the scale of the force they were serving. But it has now been taken over almost entirely by air craft, which to their immensely greater speed and radius of reconnaissance add the advantage of being able to pass over the enemy's screening troops. Tactical reconnaissance falls to the lot of troops of all arms, whether in contact with the enemy or for self-protection. In this task lies now the main use of cavalry, infantry divisions being usually endowed with either a regiment or a squadron. A reconnaissance by a large force of all arms with the idea of provoking an enemy into showing his hand, if necessary by fighting, is called a reconnaissance in force.

RECORD. According to Sir Edward Coke a record was "a memorial and remembrance in rolls of parchment of the proceedings and acts of a court of justice." It was the perpetuation of the terms of a ratified transaction, whether between individuals, corporations or States. Its value was precise and utilitarian. The framers of the English Public Record Office Act of 1838, defined records as "all rolls, records, writs, books, proceedings, decrees, bills, warrants, accounts, papers and documents whatsoever of a public nature." That definition may still be accepted as adequate; indeed, its comprehensive vagueness is a virtue; but it has to be observed in qualification, that the documents which are not strictly speaking of a public nature are often included and classified with public archives: as, for instance, the many private letters which are to be found in the English State papers.

On the other hand, a great many documents of a public nature have passed into private possession. So lax were ideas as to the proper custody of official papers before the 19th century, that it was quite usual for a minister of State leaving office to take his correspondence with him. Thus, to cite one instance out of many, at Hatfield, Hertfordshire, the seat of the marquess of Salisbury, there is a mass of correspondence of Lord Burghley, Queen Elizabeth's famous Lord Treasurer, and of his son the first earl of Salisbury, secretary of State both to Elizabeth and her successor, which constitutes a body of State papers of greater value than the contemporary documents of similar character preserved in the Public Record Office. The importance of making accessible to students the historical wealth of private archives was recognized in England by the appointment of the Historical Manuscripts Commission and has been a great stimulus to the foundation of learned societies in all countries. The breaking-up of the old family collections, and their frequent emigration from the land of their provenance, due to the changed economic conditions of modern times, has rendered the work of such bodies more urgently necessary than ever.

Administration.—The respective merits of the centralization of records and the system under which they are kept in local or specialized repositories has been much discussed. Most European countries, the United States of America, the Dominion of Canada and the Union of South Africa, following the pioneer example of France, have preferred the second plan. Broadly speaking, each has a central repository wherein are kept records which concern the country as a whole, and also a series of provincial repositories, which may easily be of more importance to the historical student than the central repository.

The outstanding example of the policy of centralization is England and Wales.

By the Act of 1838 all separate collections in the country were brought together and placed under the charge of the Master of the Rolls, who was to appoint a deputy and a staff of assistant archivists to look after them and to define the terms on which they should be accessible to the public. Moreover the Act empowered the Crown to bring within its scope, at discretion, any groups of documents of a public nature which were not included in the original schedule. In 1854, under an order in council made two years earlier, this provision was applied to the contents of the old State Paper Office, which had existed, in one form or another, since the 16th century and constituted a very important branch of the national archives; and subsequently arrangements were made for the transference to the Public Record Office of the records of all government departments, with the exception of the India Office, so soon as they should cease to be needed for administrative purposes.

The collection thus garnered in the Record Office, London, falls into two divisions, the judicial records and the State papers, with which latter are included the records of the various departments into which the old secretaries' offices have become differentiated. Of the former, the two most important branches are the Chancery and the Exchequer.

Judicial Records.—The Chancellor formerly acted as the private secretary of the sovereign. To the records of the Chancery, therefore, belong the series of enrolled royal letters, the Patent and Close rolls, both of which began in the reign of King John. The formal difference between these two series is implied in their names: the letters patent were sent open, with the Great Seal attached, while the letters close were sent folded. On the patent rolls were entered grants of lands, offices and privileges whether to private persons or public bodies, creations of peerages, licenses for the election of bishops and restitutions of temporalities, presentations to ecclesiastical benefices, charters of incorporation to towns, pardons, etc. The earlier rolls also contain the records of diplomacy which were afterwards to find their place among the State papers, such as the powers and credentials granted to ambassadors, correspondence relating to negotiations with foreign States, and treaties. The contents of the letters close, which were addressed to individuals and are generally of a more personal nature than the letters patent, are of a very varied description, "such," to quote Sir Thomas Hardy, a former deputy-keeper, "as orders for the observance of treaties and truces, concerning aids, subsidies, tallages, restitutions of possessions, assignments of dower, and acceptances of homage; for the repairing, fortifying, and provisioning of castles; writs and mandates respecting the coin of the realm, the affairs of the royal household, and the payment of salaries and stipends; commitments, pardons, and deliveries of State prisoners, etc."; while "on the back of the rolls are summonses to and prorogations of parliaments, great councils, and convocations; writs of summons for the performance of military and naval services; copies of letters to foreign princes and states; proclamations; prohibitions; orders for regulating the coinage of the kingdom, and the sale of wine and other necessaries; for receiving knighthood, providing ships, raising and arraying forces, and furnishing provisions; for paying knights, citizens and burgesses for attendance in parliament; liveries and seizin of lands; enrol-

ments of private deeds, of awards of arbitrators and of various other documents."

It will thus be seen that the close rolls of which there are more than 20,000 are of immense importance for social as well as for political history. Besides these two great series, both of which are continued in the 20th century, there are the Charter roks (1 John to 8 Henry VIII.) containing grants and confirmations of a more formal type than those enrolled on the Patent rolls; the Fine rolls (John to 23 Charles I.) recording moneys paid to the king for various grants, privileges and exemptions; and the Parliament Rolls (1 Edward III. to 49 Victoria) containing entries of the transactions in parliament, and various smaller series of a special character.

Of unenrolled Chancery documents may be mentioned the warrants which formed part of the process of issuing letters under the Great Seal, the inquisitions containing details of the holdings of deceased tenants-in-chief and, appertaining to the court in its judicial aspect, the Chancery proceedings, comprising bills and answers, affidavits and depositions, decrees and orders.

The Exchequer records, of which the oldest and most famous is Domesday Book (*q.v.*) may be most conveniently described according to the ancient divisions of the court, of which the principal were the Upper Exchequer or Exchequer of Audit and the Lower Exchequer or Exchequer of Receipts. The former was subdivided into the Treasurer's Remembrancer's Office and the King's Remembrancer's Office. To the first belong the Pipe rolls (*q.v.*), containing the first audit of the accounts of the sheriffs, the Foreign rolls on which were entered the preliminary audit of accounts other than the sheriffs', the Originalia rolls, containing extracts from Chancery rolls communicated to the Exchequer for information, and the Memoranda rolls, containing copies of correspondence and miscellaneous notes. The principal records of the King's Remembrancer's Office consist of vouchers and audited receipts of expenditure. There are also judicial records belonging to this department, comprising bills, answers, depositions, etc., as in the Chancery. The records of the Lower Exchequer consist of the Receipt and Issue rolls, in which, respectively, are entered the payments made to and by the Exchequer. A special subordinate court heard suits in which Jews were involved, and there is a separate series of plea rolls appertaining thereto; and after the Reformation, to meet the greatly increased business of the Exchequer resulting from the transference of Church lands to the Crown, new divisions were created. From that period date the records of the First Fruits and Tenths Office, including the Valor Ecclesiasticus, a survey of all the ecclesiastical benefices in England and Wales made in 1535, and also those of the court of Augmentations, which administered the property of the suppressed religious houses and the revenues of the Duchy of Cornwall and was merged in the Exchequer in the reign of Queen Mary: its records consist of the muniments of the monasteries, documents relating to their seizure and subsequent administration, and judicial proceedings.

Common Law Records.—The earliest common law records are the Curia Regis rolls (5 Richard I. to 56 Henry III.), which contain pleas heard in the courts both of King's Bench and of Common Pleas. From the beginning of the reign of Edward I. the records of the two courts are separate, the most important of those belonging to the King's Bench being the Coram Rege rolls, the Judgment rolls, containing suits between private persons, the Crown rolls, recording crown business, and the Assize rolls, containing the proceedings before justices in eyre, of assize, of oyer and terminer, etc. The early plea rolls of the Court of Common Pleas are called De Banco rolls; from 24 Henry VII. they were known as Common rolls, and in 25 Elizabeth a new series of Recovery rolls was commenced, in which, besides deeds and other instruments, were entered the recoveries forming part of the complicated legal process of fine and recovery by which, down to 1834, the transfer of land was effected. The Feet of Fines, which date from the reign of Richard I. and are arranged under counties, form another group of Common Pleas records.

State Papers.—As has already been noticed, many documents which are essentially State papers are to be found on the earlier Chancery rolls, and there is a series of Ancient Correspondence, running from the reign of Richard I. to that of Henry VII. and filling 61 volumes, which comes under that category. But the great series which was preserved in the State Paper Office established in 1578, and absorbed by the Public Record Office nearly three centuries later, begins with Henry VIII. From the time of Edward VI. they were divided into two classes, domestic and foreign, according to whether they appertained to the internal or the external affairs of the kingdom; and to them were subsequently added the State Papers Colonial. While, however, in the arrangement of documents adopted by the Record Office, the two former series have been kept separate from the subsequent records of the Home and Foreign Offices founded in 1782, the State Papers Colonial have been amalgamated with those of the Colonial Office. There are also separate series relating to Scotland and Ireland, and there are special calendars of papers relating to Border affairs from 1560 to 1603 and to the reign of Mary Queen of Scots and the subsequent regency (1547–88), and of Irish State Papers from 1509 to 1670. From the last-mentioned date onwards the papers of both countries are described in the Calendars of State Papers Domestic.

The Domestic series comprise royal and secretarial correspondence, both letters received (in-letters) and letters despatched (out-letters), whether in the form of loose drafts or of copies entered into bound volumes (Entry Books), warrants, dockets (abstracts of warrants), orders, commissions, petitions and a host of miscellaneous material, among which are to be found a number of collections of private correspondence. Those belonging to the Commonwealth period, when the affairs of the kingdom were administered almost entirely by committees, take on a special character. The State Papers Foreign, which from 1577 are arranged according to the foreign countries which they concern, consist in the main of correspondence between ambassadors and secretaries of State, treaties and treaty papers (records of negotiations), archives of British legations abroad and memorials and letters from foreign ministers in England.

Record Publications.—In 1800 a royal commission was appointed which was charged with the arrangement and publication of public records and the control of repositories. So far as arrangement and control were concerned practically nothing was done, but a number of calendars were published. The contractions of the original documents have not been expanded, no attempt has been made to identify names which may be spelt in a dozen different ways, they abound in inaccuracies of transcription and their indexes are utterly inadequate. The calendars prepared at the Public Record Office are a very different matter. Though it must still be many years before the collection, even excluding the modern departmental papers, has been completely described, great progress has been made with most of the more important series of records and some hundreds of volumes have already been issued. The tendency, moreover, has been towards a greater and greater completeness of presentation; so that the student, unless he wish to make an exact and verbatim transcript of a particular document, can work independently of the originals. Nor has attention been paid exclusively to records housed in the office itself. The series of *Letters and Papers of Henry VIII.* includes documents in the British Museum, at Oxford and Cambridge and elsewhere, and papers relating to English affairs in various foreign archives (Rome, Venice, Salamanca) have been calendared by delegates sent out for the purpose. Moreover, much valuable critical work has been done on the public records by unofficial learned bodies, such as the Pipe Roll Society and the Selden Society.

Records Commission of 1910.—In 1910, a royal commission was appointed to make exhaustive enquiry into the preservation of records. The reports of the commission, completed in 1929, were a condemnation of the policy of excessive centralization and an endorsement of that of the territorial administration pursued in France and elsewhere. So far, however—that is to say in 1928—no steps have been taken by the State to carry the recommendations of the commission into effect.

Not, by any means, that the local records of England, whether

municipal, parochial or ecclesiastical, have been universally neglected. Moreover, much has been done in the way of publication, whether of the records of a particular town or parish or by specialists in a particular kind of record, such as Dr. Charles Gross in his classic *Gild Merchant* or A. Ballard in his *British Borough Charters*, or by such bodies as the Parish Register Society or the various societies connected with particular counties. But all this activity has been the result of private enterprise and local patriotism: it has been neither controlled nor officially recognized by the State. Signs, however, are not wanting that the findings of the commission of 1910 will eventually bear fruit. By the Law of Property (Amendment) Act of 1924 Manorial documents were brought under the control of the Master of the Rolls, without whose consent such records, as valuable to the social historian as they are liable to dispersal, might not thenceforth be disposed of; and the Surrey County Council appointed a records committee which in 1928 published a volume of abstracts of civil and ecclesiastical records and another of manorial court rolls preserved in the county.

United States of America.—The federal records of the United States are kept in the Library of Congress at Washington, and each State has its own archives. These are independent of the national Government, and various systems of administration are in force. "There are departments of archives and history, divisions of archives in State libraries, State historical commissions and State historical societies charged with some of the functions of archivists" (Botha). The American Historical Society, with its archives commission and historical manuscripts commission, which, like the similarly named body in England, devotes itself to the exploration of private collections, has done admirable work. But American history begins long before America had a national entity, and the student must seek much of his material in Europe. His principal sources are the Colonial State Papers and the Journal of the Board of Trade and Plantations in the Public Record Office of London, but there are many others. Excellent guides have been compiled by Mr. Andrews of manuscripts relating to the United States in the Public Record Office, the British Museum, the libraries of Oxford and Cambridge, the House of Lords, and other repositories, but that there are still untapped sources is indicated by the recent discovery among the archives of Bristol of the Tolzey books, recording the names of 12,000 to 15,000 persons who emigrated, as "servants to the foreign plantations," to Virginia, Maryland and the West Indies in the third quarter of the 17th century.

Scotland, Ireland, and the Dominions.—The principal records of Scotland are kept in the General Register House at Edinburgh. They include the registers of the privy council and the rolls of the Exchequer and the Chancery. Other records of the Chancery remain in the custody of the court, and the Court of Teinds (tithes) also keeps its own records. There are also local records of great interest (*see* Murray, *Scottish Local Records*, 1927). The Reorganization of Offices (Scotland) Act (1928) abolished the office of Deputy Clerk Register, whose duties, with those of the Keepers of the Registers, of Sasines and of Deeds, were transferred to a Keeper of the Registers and Records of Scotland. For Ireland a Public Record Office was established in 1867 and to it were transferred the records of the various courts of law, wills proved in Ireland and certain financial records; the State Paper Office remaining a separate institution though under the control of the deputy-keeper. The most valuable Irish State Papers, however, numbering 500 volumes and ranging in date from the reign of Henry VIII. to 1771, are in London. On the other hand five important volumes containing correspondence and other papers of the early 17th century, discovered in Philadelphia in 1866 by Hepworth Dixon, the historian and traveller, and on his suggestion offered to the British Government, were, on the suggestion of Lord Romilly, at that time Master of the Rolls, presented to the Irish Record Office.

If the historian of Scotland or Ireland must seek for many of his sources of information in England, still more is this the case of the colonial historian. Nevertheless, the dominions have their own records also, and within recent years a good deal of attention has been paid to their administration. Both in South Africa and in Canada the policy of provincial repositories is favoured, the four members of the Union and the provinces of Canada having their own archives. Mr. C. Graham Botha, chief archivist for the Union of South Africa, after the War made a tour of inspection of the principal record offices of Europe and America and his report, published in Pretoria in 1921, is a very valuable survey of the conditions of archive administration throughout the civilized world. Canada has taken steps to augment its own records by the foundation of history societies in England and France for the discovery, preservation and publication of documents relating to its history in those countries.

The Continent of Europe.—In the care and disposal of records France was a pioneer. A carefully considered policy was laid down in 1789 and has ever since been adhered to. The national archives, divided into three sections, *historique, administrative et domaniale* and *legislative et judiciare* are kept in the Hôtel de Soubise in Paris. Each of the departments keeps its own records, consisting both of those of the old provincial governments and those of the post-revolutionary administrations; and these are under central control and arranged on a uniform system of classification. Beyond these are the municipal and communal archives and the *archives hospitalières*. The greater part of these records have been carefully inventoried; and besides a severely logical and consistent method of administration, France possesses in the *École de Chartes* an institution for the scientific study of records which has been imitated but never rivalled.

Most European countries, as already noted, have followed, with varying degrees of precision, the example of France. In Switzerland and Holland, for instance, there are separate repositories for each of the cantons and States, with central offices at Berne and The Hague respectively. The *Reichsarchiv* of Germany, which was taken over by the new Government in 1919, are kept at Potsdam and the States comprising the *Reich* each have their own archives, there being in Prussia, besides the chief collection at Berlin, no less than 16 provincial repositories. The municipal records of such towns as Frankfurt and Cologne are of great value. In Italy there are 17 repositories, under the control of the ministry of the interior, representing the ancient divisions of the country. The archives of the Vatican stand, of course, in a separate category. With regard to the publication of records the method adopted in Holland is particularly worthy of note. Early in the 20th century a *Commissie van Advies voors Rijks Geschiedkundige Publicatien* was set up, consisting of ten leading historical scholars who meet three or four times a year. Under the direction of this body a series of volumes has been published, the value of which is far from being confined to the Netherlands.

(F. B.)

RECORDER. The principal legal officer of an English city or borough having a court of quarter sessions. He must be a barrister of five years' standing, appointed by the Crown. The recorder holds, once in every quarter of a year, or oftener, if he thinks fit, a court of quarter sessions in and for the borough. He is sole judge of the court, "having cognizance of all crimes, offences, and matters cognizable by courts of quarter sessions for counties in England," except that he may not allow or levy any borough rate, or grant licences (s. 165). He is not eligible to serve in parliament for the borough, or to be an alderman or

councillor, or stipendiary magistrate for the borough, though he is eligible to serve in parliament except for the borough. He may be appointed recorder for two or more boroughs conjointly. Appeals from the city and borough justices, and under the Rating and Valuation Act, 1925, are to the recorder as sole judge.

The recorder of London is judge of the lord mayor's court, and one of the commissioners of the central criminal court. (*See* QUARTER SESSIONS, COURT OF.)

In the United States, most of the States have county recorders elected by the voters of the county. In some of the States, the duties of the recorder fall upon the clerk of one of the courts. In all of the States provision is made by Constitution or statutes for some official to have the duty of recording deeds and other legal instruments.

RECORDER, FIPPLE FLUTE or **ENGLISH FLUTE,** a mediaeval flute, blown by means of a whistle mouthpiece and held vertically in front of the performer like a clarinet. The recorder only survives now in the almost obsolete flageolet and in the so-called penny-whistle. It consisted of a wooden tube, which was at first cylindrical or nearly so, but became, as the instrument developed and improved, an inverted cone. Being very easy to play, the recorder enjoyed great popularity in all countries until the greater possibilities of the transverse flute turned the tide against it. The want of character which distinguishes the timbre of instruments of this type is due to the paucity of harmonic overtones represented.

RECTIFIER, as used in radio, consists of a device for the direct conversion of an alternating-current wave into a unidirectional wave.

RECTOR, a title given to the bearers of certain ecclesiastical and academical offices. In the Roman empire, after Constantine, the title *rector* was borne by governors of provinces subordinate to the prefects or exarchs. In the middle ages it was given to certain secular officials, *e.g.*, the podestas of some Italian towns, but more especially to the heads of the universities, the representatives and rulers of the *universitas magistrorum et scholarium*, elected usually for a very short time. After the humanistic movement of the Renaissance the style *rector* was also given to the chief masters of schools containing several classes, and in some parts of Germany (*e.g.*, Saxony, Württemberg) it is still thus used instead of the more modern title of *director*. Rector is also still the title of the heads of the Scottish universities (*Lord Rector*) and of the German universities (*Rector Magnificus*). *Rector* is the title of the heads of Exeter and Lincoln Colleges, Oxford. The heads of all Jesuit colleges are known as *rectors*.

As an ecclesiastical title *rector* was once loosely used for rulers of the Church generally, whether bishops, abbots or parish priests (*see* Du Cange, *Rectores ecclesiarum*), but the ecclesiastical title *rector* became ultimately confined in certain parts of Europe (Poland, Spain and notably England) to the office of a priest having a cure of souls.

RECUSANT (Lat. *recusare*, to refuse), the name given in the sixteenth and seventeenth centuries to persons, particularly to adherents of the Roman faith, who persisted in refusing to attend the services of the English Church, and became thereby liable to prosecution and penalties (*see* ROMAN CATHOLIC CHURCH: *English Law*).

RED BANK, a borough of Monmouth county, New Jersey, U.S.A., on an estuary called the Navesink river, 6 m. from the Atlantic ocean and 25 m. (in a bee line) S. of New York city. Pop. (1920) 9,251 (14% foreign-born white and 10% negro). It is served by the Central of New Jersey and the New York and Long Branch railways, interurban trolleys, motor-bus lines and steamers to New York. It is a residential suburb, a summer resort and the trade centre of a rich farming region; and has fish and oyster industries, canneries, nurseries and various manufacturing plants. The name Red Bank was applied to this locality as early as 1734, and by 1780 there were several buildings within the limits of the present borough. In 1843 a Fourierist community, the North American phalanx, was established near by on 673 ac. of land with 112 members. It dissolved in 1855.

REDBREAST or **ROBIN,** a favourite among English birds because of its pleasing colour, its sagacity and fearlessness of man, and its song. In July and August the hedgerows of the southern counties of England are beset with redbreasts, each bird keeping its own distance from the next, on their way to cross the English Channel. A number of these redbreasts, as well as native birds, remain throughout the winter. On the Continent the migration is still more marked, and the redbreast is then caught in numbers for the table. The first sharp frost makes them change their habitation, and a heavy fall of snow drives them towards the homesteads for food. The nest is usually built of moss and dead leaves, with a lining of hair. In this are laid from five to seven white eggs, sprinkled or blotched with light red. Two or three broods are raised. On the Continent, the redbreast is, on the whole, a forest bird, not frequenting houses like the British form.

Although the female has a breast only a little duller than the male, the latter alone displays the red in courtship. After the young are reared fights take place between them and the adults for the possession of the territory for the winter. The robin, like most insectivorous birds, throws up the indigestible parts of its food in the form of pellets.

Besides the British islands, the redbreast (*Erithacus rubecula*) is generally dispersed over Europe, and is in winter found in the oases of the Sahara. In northern Persia it is replaced by a nearly allied form, *E. hyrcanus*, distinguishable by its more ruddy hues, while in northern China and Japan another species, *E. akahige*, is found, of which the sexes differ in plumage—the cock having a blackish band below his red breast and greyish-black flanks, while the hen resembles the British species—but both sexes have the tail chestnut red. The genus *Erithacus* belongs to the family *Turdidae* or thrushes (*q.v.*).

English colonists in distant lands have applied the common nickname of the redbreast to other birds. The ordinary "robin" of North America is a thrush (*see* ROBIN), and one of the blue-birds (*q.v.*) of the same continent, is in ordinary speech the blue "robin"; the Australian and Pacific "robins" have not all even the red breast; the Cape "robin" is *Cossophya caffra*, the Indian "robin" *Thamnobia* and the New Zealand "robin" *Miro*.

RED-BUD: *see* JUDAS-TREE.

REDCAR, a municipal borough in the north riding of Yorkshire, England, 8 m. N.E. of Middlesbrough on the L.N.E. railway. Pop. (1921) 16,401. It is situated on the north-east coast of Yorkshire, midway along the continuous stretch of sand beaches between the Tees estuary and Saltburn. It thus serves as a residential town and a holiday resort for the dense industrial population employed in Middlesbrough. During recent years, the population has grown so rapidly that the one time separate villages of Redcar and Coatham have coalesced into one compact town. Redcar is the youngest borough in Yorkshire, incorporation having been granted in Nov. 1922. Since the last census over 1,200 new houses have been built and the population is estimated (1928) at 21,500.

RED CROSS, the national and international agency whose primary purpose is to care for the sick, the wounded and prisoners in time of war. The development of the Red Cross movement, especially since 1919, has shown a world-wide tendency to regard the alleviation of human suffering, whatever its source, as falling within the purview of the Red Cross.

The Origins of the Movement.—The fundamental idea which has come to be associated with the Red Cross was first enunciated as the result of the publication by Henri Dunant, at Geneva, in 1862, of a booklet entitled *Un Souvenir de Solférino*. Dunant had witnessed appalling scenes of bloodshed during the war in Italy and his booklet gives a shocking account of the distress of the wounded left to perish on the battlefield for lack of medical assistance. He urged the necessity of constituting permanent societies for the aid of the wounded, with the purpose of forming detachments of volunteer helpers; and he went on to express the hope that he might live to see "the leaders of the military art of different nationalities agree upon some sacred international principle, sanctioned by convention, which, once signed and ratified, would serve as the basis for the creation of

societies for the aid of the wounded in the different European countries."

Dunant's appeal quickly found its echo. The *Société Genevoise d'Utilité Publique* had as president M. Gustave Moynier, who was greatly struck by the importance of the suggestions set forth in the *Souvenir de Solférino* and at his request Dunant attended a meeting of this society and explained his ideas before it. The members of the society thereupon nominated a commission with instructions to study the means of improving the position of the wounded in war. The original members of this commission, which was destined to become the *Comité International de la Croix-Rouge*, were: Gen. Dufour, commander-in-chief of the Swiss army, Gustave Moynier, Henri Dunant, Dr. Louis Appia and Dr. Théodore Maunoir.

Their first task was to draw up a draft agreement providing for the formation of national committees having as purpose to assist army medical services by creating voluntary aid corps. They further proceeded to summon an international meeting, which assembled at Geneva from Oct. 26 to 29, 1863. Thirty-six experts and Government delegates were present at the Palais de l'Athénée, and there were laid down the fundamental principles of the Red Cross.

The International committee was urged to continue the mission which it had assumed as guardian of the principles laid down in the Convention, and to pursue the formation of national societies in all countries for the purpose of developing the Red Cross movement and organizing aid for wounded soldiers and for the other victims of war.

The next step was to secure an international legal status for the movement which had thus been set on foot, ensuring the wounded men themselves, the personnel engaged in the care of the wounded and the medical supplies set aside for their use against attack, the whole being protected by a single recognized emblem. The difficulties were enormous, but they were successfully overcome thanks to the weight carried by the name of Gen. Dufour, the unwearying activity of Henri Dunant (who personally approached the authorities in a number of different countries), and the methodical organizing work of Gustave Moynier. Napoleon III. brought his personal influence to bear in favour of the scheme, and the International committee succeeded in inducing the Swiss Federal council to convoke in Geneva on Aug. 8, 1864, a diplomatic conference at which 26 Governments were represented. The outcome of this conference was the Geneva Convention, which laid down certain principles once and for all. The wounded were to be respected, military hospitals to be regarded as neutral; the personnel and material of the medical services were accorded protection; and the symbol of this protection was to be a white flag bearing a red cross—the flag which has now become the emblem of the Red Cross throughout the world. Almost all countries have now adhered to the Geneva Convention, which was revised and completed on July 6, 1906, by a new diplomatic conference. The conferences held at The Hague in 1899 and 1907 extended to sea warfare the principles of the Geneva Convention of 1864 and the revised Convention of 1906.

THE INTERNATIONAL RED CROSS COMMITTEE (COMITÉ INTERNATIONAL DE LA CROIX-ROUGE)

The objects of the International Red Cross are regarded as being: To extend the Red Cross movement to all countries; to act as guardian of the basic Red Cross principles; to notify to existing societies the constitution of new Red Cross societies; to induce all civilized States to adhere to the Geneva Convention; to ensure the observance of the Convention, denouncing such violations of it as may occur; to urge Governments to pass legislation or issue army orders to prevent such violations; to create in time of war international agencies for the assistance of prisoners and other war victims; to visit prisoners' camps, afford prisoners of war comfort and consolation, and try to better their situation by use of all available influence; and in time of peace as well as in time of war, to act as a benevolent intermediary between Governments, peoples and nationalities, for the purpose of itself carrying out or making it possible for others to carry out the humanitarian task of relieving suffering arising out of war, sickness or disaster.

Work in War-time.—A few examples will serve to indicate the extent of the International Red Cross committee's activities. The formation of independent national Red Cross societies and the acceptance of the members of the Geneva Convention made rapid headway from the beginning. In 1870 an information agency was formed by the international committee at Basle for the benefit of French and German wounded or sick soldiers.

In 1912 during the Balkan War the committee constituted a similar agency at Belgrade. When the World War came, in 1914, there was constituted in Geneva an international agency for prisoners of war with a staff of 2,000 persons, mainly volunteers. The 17 different sections of this agency dealt with requests emanating from 30 belligerent countries. From 2,000 to 15,000 letters a day were handled, and the index of requests for information included before the end of the war over 5,000,000 cards. Thanks to this agency, thousands of missing men of different armies and navies were traced, assistance was forwarded to prisoners of war, regular visits were made to 500 different internment camps, and facilities were obtained for the evacuation of civilians from occupied districts, and for the repatriation or internment in neutral territory of the more severely wounded, of certain categories of sick prisoners and of medical personnel. The financial service of the international agency had transmitted to prisoners of war in cash up to Dec. 31, 1917, a sum of over £715,000.

As regards breaches of the Geneva Convention, frequent representations have been made to Governments by the international committee, concerning cases of hospitals being shelled, reprisals exercised, medical personnel or wounded improperly treated, medical stores belonging to Red Cross societies requisitioned, the Red Cross emblem abused, etc.

Post-war Activities.—At the end of hostilities the international committee, thanks to the generous aid given by the League of Nations, was able to organize arrangements for the repatriation of prisoners of war of all nationalities who remained in Russia and Siberia, and the return of Russian prisoners from the different countries of central Europe. The delegates of the committee were called upon to undertake representations to the Governments concerned, to form prisoners into convoys and check their identity, to look after their health, and to arrange for the movements of convoys between Moscow and the Baltic ports and between Vladivostok, Novorossisk and Trieste. Half a million prisoners were thus repatriated.

At a later date the delegates of the international committee were concerned with the exchange of Polish and German hostages in Upper Silesia, with the return of Bulgarian subjects interned in Greece and with the exchange of prisoners between Greece and Turkey.

In regard to health work, the representatives of the international committee in Galicia and Ukraine and in the Black sea region were instructed in 1918 to lend their assistance in combating the typhus epidemics then raging. In April 1918, the committee participated with the representatives of different countries in central and eastern Europe in founding a central study bureau for the combating of epidemics. Between 1921 and 1923, two medical missions were sent into the Ukraine to equip hospitals and supply food to famine sufferers. The committee's representatives in Poland were associated in the anti-epidemic campaign there and between 1919 and 1923 a number of sanatoria and dispensaries in the Black sea region were re-established and equipped by the committee.

In order to assist in the relief of the populations most heavily affected by the economic consequences of the war, the committee undertook the systematic co-ordination of relief activities in Austria and Hungary. On Aug. 15, 1921 the committee joined with the League of Red Cross societies (*see* p. 18) in summoning in Geneva an international conference comprising 80 representatives of governments, Red Cross societies and relief agencies, to organize relief for the famine stricken districts of Russia. A Russian relief committee was designated with Dr. Nansen as high commissioner, and the funds handled by this committee up to Jan. 1922, amounted to over £800,000. In 1923 the economic

position of the population in Germany and in the Ruhr was also investigated by delegates of the committee.

It was impossible to ignore the very special hardships to which children were exposed during the war and the years immediately following the conclusion of hostilities, and in order to facilitate the relief of children so situated the international committee participated in Jan. 1920 in founding the international Save the Children union, of which it became patron. The distribution of the relief funds handled by the union has been largely effected through the delegates of the international committee, and it is estimated that over £4,000,000 has been so distributed.

On numerous occasions the committee has been called upon to act in connection with civil war. Political prisoners arrested in the case of internal disorders in Hungary, Ireland, Posnania, Lithuania, the Ukraine and Montenegro have at various times been visited by representatives of the committee.

The refugee problem has also been one of the committee's principal preoccupations of recent years, when wars and revolutions have raised it in an acute form. The international committee pointed out at an early date the necessity of providing permanent homes for the thousands of Russian refugees who poured out of Russia into neighbouring countries. It was necessary that they should be transported to regions in which they could establish themselves without disturbing the balance of the economic life of the countries receiving them. The committee made representations on this subject to the League of Nations and a high commissariat was formed to handle the matter. In Europe and the Near East the executive work incurred was largely handled by the delegates of the committee; in particular direct assistance was rendered by the committee to Greek refugees from Asia Minor, to war victims in Anatolia and to Syrian refugees.

As regards the general problem of relief, the international committee gave its support from the outset to a plan conceived by Senator Ciraolo and supported by the League of Nations, for the constitution of an international federation for the mutual relief of disaster stricken populations. This organization—the International Relief union (*Union Internationale de Secours*)—is to be entrusted with organizing and co-ordinating general relief on an adequate scale for peoples suffering under disasters of an exceptional character. The statutes of the union, to which a number of Governments have already given their adhesion, provide that the International Red Cross committee and the League of Red Cross societies shall assume responsibility for the permanent central services of the union.

An important contribution to the technical documentation available regarding relief problems has been made by the foundation in 1923 of a review entitled *Matériaux pour l'étude des calamités*, which is published by the Geneva Geographical Society under the joint auspices of the international committee and the League of Red Cross societies.

The international committee has been frequently called upon to collaborate with the technical services of the League of Nations and the International Labour office. It has followed with great interest the question of medical personnel, which is so closely connected with the whole history and work of the Red Cross. It has also established close co-operative relations with the International Council of Nurses and with the world conferences called at regular intervals by that council.

In 1921 and 1925 general exhibitions of medical stores and supplies were organized at Geneva by the committee, with the participation of the army and navy medical services of various countries, national Red Cross societies and representatives of private firms. The purpose of these exhibitions was to draw attention to the international side of the question of medical stocks, and the advantage which could be derived from the adoption of certain measures of standardization which would facilitate the use of such stocks for the relief of the sick and wounded. In this connection, in accordance with a resolution of the 12th International Red Cross conference, the committee has founded in Geneva an international institute of medical material (*Institut International de matériel sanitaire*), including a permanent museum of exhibits forwarded from official sources and by national Red Cross societies. This unique collection enables students of these questions to study and compare the practices of the medical services of different countries. They include specimens of different types of stretchers and of contrivances for carrying and moving wounded men, as well as specimens of bandages, identity discs and wounded men's identity cards, together with charts, photographs, documents, etc. In this same connection the committee has formed an international commission for the standardization of medical material, the members of which have been designated by the army medical services of different countries. The commission has met at regular intervals since 1926 and has arranged competitions and experimented with different types of apparatus. The purpose of its work is to determine upon standard types of stretchers, racks, bandages, identity cards and Red Cross brassards.

In addition the international committee has undertaken the study of a number of questions of general humanitarian interest, such as chemical warfare, the position of non-combatants in enemy territory, the protection of air ambulances, the abuse of the Red Cross emblem, etc. The committee has been entrusted by the International conferences with the periodical distribution of Florence Nightingale medals, which are awarded to the most deserving nurses of all countries; and with the distribution of the interest accruing from the empress Shoken and the Augusta funds in favour of humanitarian enterprises and all activities concerned with Red Cross work.

The International Red Cross committee was formed at Geneva where it continues to have its headquarters. Its president from 1863 to 1910 was Gustave Moynier, founder of the committee. Moynier was succeeded by Gustave Ador (*q.v.*) who was succeeded on his death in 1928, by Max Huber (*q.v.*) judge and late president of the Permanent Court of International Justice. The committee is recruited by co-optation and under the terms of its by-laws, possesses juridical personality. The international committee provides the national societies with inspiration, and serves to maintain contact between them and to co-ordinate their activities. The principles upon which its activities are based remain as they have always been, absolute impartiality, complete independence (particularly from the political and confessional standpoint) and equality as between all members of the great Red Cross family. A link between the committee and the national societies is provided by a periodical publication, the *Bulletin International de la Croix-Rouge*, supplemented since 1919 by the *Revue Internationale de la Croix-Rouge*, which contains articles and information concerning the different aspects of the Red Cross movement. The international committee also publishes books, pamphlets, etc., dealing with Red Cross activities. (M. H.)

LEAGUE OF RED CROSS SOCIETIES

The League of Red Cross societies was formed in 1919 on the proposal of H. P. Davison, president of the War Council of the American Red Cross, by the Red Cross societies of France, Great Britain, Italy, Japan and the United States, for the purpose of developing and intensifying the humanitarian activities of the Red Cross in time of peace. By 1928 the league had grown to include 50 national Red Cross societies, and its statutes, revised in 1924 and again in 1927, define its objects as follows:

The objects of the league are to encourage and facilitate at all times Red Cross action for the relief of suffering humanity. It shall for this purpose:

1. Encourage and promote in every country, the establishment and development of a duly authorized voluntary national Red Cross organization working in accord with the principles of the Geneva Convention.

2. Collaborate with these organizations in the improvement of health, the prevention of disease and the mitigation of suffering.

3. Place within the reach of all peoples the benefits to be derived from present known facts and new contributions to science and medical knowledge and their application.

The league has a board of governors comprising one representative of each member society, and the board, when not in session, delegates its authority to an executive committee of ten members. The expenses of the league are met by the voluntary contributions of member societies, the greater part of the financial burden having thus far been carried by the American Red Cross. More

than 30 national societies, however, make annual grants towards the league's budget.

The international activities of the league are carried out under the direct supervision of the chairman of the board of governors or one of the three vice-chairmen, by an international secretariat whose headquarters, originally situated in Geneva, were transferred to Paris in 1922. It comprises in addition to the various branches of the secretary-general's office, technical divisions corresponding to the principal peacetime activities of Red Cross societies, viz., disaster relief; health (with special emphasis on popular health education and preventive activities); nursing; junior Red Cross; and emigration.

The foundation of the league preceded by a few weeks the signing of the covenant of the League of Nations, of which article 25 reads as follows:

> The members of the league agree to encourage and promote the establishment and co-operation of duly authorized voluntary national Red Cross organizations having as purposes the improvement of health, the prevention of disease and the mitigation of suffering throughout the world.

This confirmation in the Covenant of the central points in the league's programme was indicative of the widespread sentiment which lay behind the decision of the national Red Cross societies after the war to widen their horizon and to extend their activities to the relief of all forms of preventable suffering. The most immediate tangible result of this decision, and of the consequent activities of the League of Red Cross societies has been the extension of the Red Cross movement into a large number of countries to which it had not previously penetrated—in particular to the countries of the South American continent, where the association of the Red Cross with the idea of war had not found favour, but where the idea of a great international movement grouping together all the principal elements which seek to protect mankind against its natural enemies in time of peace, made an immediate appeal.

The league secretariat has actively co-operated in the organization of 23 national Red Cross societies in countries where no independent and duly recognized Red Cross societies existed prior to 1919.

Parallel with this increase in the number of societies existing has come an increase in the Red Cross membership all over the world. At the end of 1925 it could fairly be estimated that the total number of Red Cross members in the world (including junior members) amounted to over 17,000,000.

The functions of the league being essentially those of a clearing house, destined to enable the different national Red Cross societies to avail themselves of each other's experience, and to co-operate readily when need arises, special attention has been given by the secretariat to the problem of creating opportunities for frequent and regular contact between Red Cross representatives from different countries. Since 1922 a system of study visits has been inaugurated under which delegates from different societies desirous of studying some particular phase of Red Cross activity, successively visit the headquarters of the league in Paris and the headquarters of such national societies in Europe as can readily afford facilities for the study in which they are interested. This system is supplemented by regular visits to the headquarters of the national societies undertaken by officers of the secretariat. A still more important innovation has been the establishment of three series of "regional" conferences. The Red Cross societies of the Far East were brought together in conference for the first time in Bangkok in 1922 and again at Tokyo in 1926. The first regional conference for the societies of central and eastern Europe was held in Warsaw in 1923 and the second in Vienna two years later. Pan-American Red Cross conferences have met in Buenos Aires in 1923 and in Washington in 1926. These meetings have been found to facilitate the exchange of views between representatives of the Red Cross societies which are concerned with similar problems owing to the similarity of the geographic, economic and social conditions of their respective countries, besides making possible the organization of collective action in regard to such problems as in their nature transcend political boundaries.

Relief Work.—As regards the activities of the league in the various technical fields already referred to (relief, health, nursing, junior Red Cross and emigration), steady and satisfactory development has taken place. The important place occupied by relief questions in the league programme is to be attributed in a great measure to the decision taken in 1924 to create a special Relief division with responsibility for preparing the ground for the work of the International Relief union referred to above. Red Cross societies are finding themselves increasingly able to handle the disaster relief problems which arise in their respective countries, without foreign help; and this is to be attributed in a large measure to the technical advice and assistance furnished by the league. Nevertheless most of the outstanding natural disasters of recent years have involved an appeal for aid from abroad; and the necessary appeal has been issued, and the resultant relief activities co-ordinated by the league either on its own responsibility or in conjunction with the International Red Cross committee. Joint appeals were launched on the occasion of the Russian famine of 1921 and in connection with earthquakes in Persia, Japan and Central America. Floods in the Low Countries and elsewhere, and the critical situation created by the influx of refugees into Bulgaria following on the exchange of populations between that country and Turkey, have also given occasion for the league's intervention in this field. Close relationship has of course been established with scientific and other organizations interested in different phases of relief problems, in order to make the equipment of the league secretariat in this field as complete as circumstances permit.

Health.—The variety of health activities upon which national Red Cross societies are now engaged is too wide to be recapitulated in a few lines. The Health section of the league secretariat has given special attention to the collection of health propaganda material, representative specimens of which it holds at the disposal of national societies. The loan collection of films in the league's possession is particularly well equipped as regards health films which are in constant demand. The commissions set up by the League of Nations to deal with health and child welfare problems include representatives of the League of Red Cross societies, which is also in close regular contact with other important international health organizations such as the *Office International d'Hygiène Publique*, the International Union against the Venereal Peril, etc. The International Union against Tuberculosis has entrusted its secretariat to the Health section of the league. Special reference may be made to the league's participation in the anti-epidemic campaign in eastern Europe in 1920–21 and to the movement in favour of creating more favourable health conditions for merchant seamen. The initiative taken by the league in this latter connection was due to representations made by the Norwegian Red Cross in 1924. A conference at Oslo in 1926, in which a number of maritime countries were represented, drew up concrete proposals in this regard and a standing committee is following developments and keeping interest alive. The International Union against Venereal Peril grew out of a somewhat similar initiative taken by the league in 1921 when conferences of specialists were called in Copenhagen, Prague and Paris, resulting in the formulation of a common basis for international anti-venereal work.

Nursing.—In the nursing field the league's most important contribution has been the establishment of an international nursing centre in London. Every year since 1920 one or more graduate nurses from each of 10 or 15 different countries has been enabled through this arrangement to follow a special course either in popular health nursing or in the work of nursing school administrators and teachers. The league has enjoyed in connection with these courses the collaboration of Bedford College for Women, where the courses are given, as well as that of the College of Nursing. The British Red Cross has given particularly helpful collaboration in this work and has presented to the league the lease of the house in London where the students are housed. The Ministry of Health and the Board of Education have also shown their interest in this almost unique experiment. The Red

Cross societies with which the league secretariat has been called upon to co-operate most closely in the development of their nursing activities include those of Albania, Colombia, Hungary and Rumania, in each of which countries Red Cross nursing schools have been inaugurated, with the help of direct assistance from the league.

Junior Red Cross.—The junior Red Cross is a relatively new departure, the origin of which is to be traced to the participation of children, during the war in 1914–1918, in the Red Cross work designated to relieve the suffering of wounded soldiers. This participation was first undertaken on an organized basis in Australia and Canada and subsequently developed on a gigantic scale by the American Red Cross when the United States entered the war. It was then observed that junior Red Cross membership constituted an ideal vehicle for the self-education of children along certain lines, notably in health and the civic idea in its fullest sense. Educationalists, especially in America, encouraged the Red Cross to develop this activity; and experiments undertaken partly by league delegates and partly by the delegates of the American Red Cross during the period when that society (in 1919–20) was conducting extensive relief operations throughout eastern Europe, sufficiently demonstrated that the appeal of the junior Red Cross idea is in no sense confined to Anglo-Saxon countries. The development of the junior Red Cross was consequently established as a definite plank in the league programme in 1922, when its purpose was defined as follows: "to inculcate in children the ideal of peace and the practice of service, especially in relation to the care of their own health and that of others, the understanding and acceptance of civic responsibility, and the cultivation and maintenance of a spirit of friendly helpfulness towards other children in all countries." By 1928 junior membership had become a recognized part of the organization of 40 different national Red Cross societies, and the number of junior Red Cross members in the world was estimated at 10,000,000.

Other Activities.—The last of the technical divisions of the league, the Emigration division, was constituted in 1925 at the instance of the Italian Red Cross, and is occupied with the collection of data regarding the particular dangers to health to which emigrants are exposed, and the degree in which Red Cross societies are in a position to assist them.

The League of Red Cross societies publishes a monthly review in French, English and Spanish entitled *The World's Health* in addition to a monthly *Information Bulletin* containing technical notes for Red Cross workers.

When the chairmanship of the board of governors of the league became vacant on the death, in 1922, of H. P. Davison, who had been the moving spirit in its foundation, John Barton Payne, chairman of the American Red Cross, succeeded him. Three vice-chairmanships were created in 1927 and the Cuban, German and Japanese members of the board of governors were nominated by the board to fill these posts. The office of director-general was entrusted, in 1919, to Lieut.-Gen. Sir David Henderson, and on his death, in 1921, to Sir Claude Hill, who resigned in 1926. The office of director-general was then abolished, and T. B. Kittredge assumed charge of the activities of the secretariat with the title of secretary-general. (P. D.)

THE NATIONAL RED CROSS SOCIETIES

The national Red Cross societies were originally constituted in almost all countries for the single purpose of supporting and assisting the Army and Navy medical services in time of war. As has already been shown, their sphere of action has since been very greatly widened. A national Red Cross society, in order to obtain official recognition, is required to fulfil the following conditions:

The Government of its country must have adhered to the Geneva Convention; the society must have been recognized as an auxiliary to the Army medical services; it must adopt the name and emblem of the Red Cross (except that in Mohammedan countries the Red Crescent, and in Persia, the symbol of the Red Lion and Sun, have been admitted); its activity must extend throughout the country and its dependencies; its membership must be open to all citizens of the country irrespective of sex, politics or religion; and, finally, it must undertake to maintain regular contact with the other national societies and with the International Red Cross committee of Geneva. No more than one national Red Cross society can be recognized in each country. Each national society is directed by a central committee and includes a suitable number of regional and local committees which assist the central committee and ensure co-operation from all sections of the country. In most cases, throughout the national organizations, there are general meetings once a year of delegates from each local branch.

National Red Cross societies are autonomous and independent within their own territory. The first national Red Cross societies came into existence in Europe immediately following the Geneva Conference of 1863, and the total number existing in the world to-day is more than 60. The list is as follows:

Albanian Red Cross (headquarters Tirana) founded in 1921.
American Red Cross (headquarters Washington) founded in 1866.
Argentine Red Cross (headquarters Buenos Aires) founded in 1880.
Austrian Red Cross (headquarters Vienna) founded in 1867.
Australian Red Cross (headquarters Melbourne) founded in 1914.
Belgian Red Cross (headquarters Brussels) founded in 1864.
(The Congo Red Cross, founded in 1924 as a branch of the Belgian society, works only in the Belgian Congo.)
Bolivian Red Cross (headquarters La Paz) founded in 1917.
Brazilian Red Cross (headquarters Rio de Janeiro) founded in 1908.
British Red Cross (headquarters London) founded in 1870.
(Independent Red Cross societies were constituted in each of the five great dominions. These societies were admitted as independent members of the League of Red Cross societies in 1919, but formal notification of the recognition of their independent status was only accorded by the international committee following the Imperial Conference of 1927. The necessary formalities in connection with the recognition of the Indian and New Zealand Red Cross societies are now in progress. The Australian, Canadian and South African societies were duly recognized in 1928.)
Bulgarian Red Cross (headquarters Sofia) founded in 1885.
Canadian Red Cross (headquarters Toronto) founded in 1896.
Chilian Red Cross (headquarters Santiago) founded in 1903.
Chinese Red Cross (headquarters Shanghai and Pekin) founded in 1904.
Colombian Red Cross (headquarters Bogotá) founded in 1915.
Costa Rican Red Cross (headquarters San José) founded in 1885.
Cuban Red Cross (headquarters Havana) founded in 1909.
Czechoslovak Red Cross (headquarters Prague) founded in 1919.
Danish Red Cross (headquarters Copenhagen) founded in 1876.
Dantzig Red Cross Society (headquarters Dantzig) founded in 1922.
Dominican Red Cross (headquarters Santo Domingo) founded in 1927.
Ecuadorian Red Cross (headquarters Quito) founded in 1923.
Estonian Red Cross (headquarters Reval) founded in 1919.
Egyptian Red Crescent (headquarters Cairo) founded in 1912.
Finnish Red Cross (headquarters Helsingfors) founded in 1920.
French Red Cross (headquarters Paris).
(Comprising three separate groups: Société Française de Secours aux blessés militaires [founded in 1864], Association des Dames Françaises [1879], Union des Femmes de France [1881].)
German Red Cross (headquarters Berlin), reorganized in 1921. (Incorporated in the German Red Cross are the following societies which previously had a separate existence:
Baden Red Cross founded in 1866.
Bavarian Red Cross founded in 1868.
Hessian Red Cross founded in 1864.
Prussian Red Cross founded in 1864.
Saxon Red Cross founded in 1866.
Württemberg Red Cross founded in 1863.)
Greek Red Cross (headquarters Athens) founded in 1877.
Guatemalan Red Cross (headquarters Guatemala) founded in 1923.
Hungarian Red Cross (headquarters Budapest) founded in 1879.
Icelandic Red Cross (headquarters Reykjavik) founded in 1924.
Italian Red Cross (headquarters Rome) founded in 1864.
Japanese Red Cross (headquarters Tokyo) founded in 1877.
Latvian Red Cross (headquarters Riga) founded in 1918.
Lithuanian Red Cross (headquarters Kaunas) founded in 1918.
Luxemburg Red Cross (headquarters Luxemburg) founded in 1914.
Mexican Red Cross (headquarters Mexico) founded in 1907.
Netherlands Red Cross (headquarters The Hague) founded in 1867.
(The Red Cross of the Netherlands East Indies is a branch of the Netherlands Red Cross society, whose activities are confined to the Dutch islands of the East Indian archipelago. The society has, however, at the request of the Netherlands Red Cross, been admitted to independent membership in the League of Red Cross societies.)
Norwegian Red Cross (headquarters Oslo) founded in 1865.
Paraguayan Red Cross (headquarters Asunción) founded in 1919.
Peruvian Red Cross (headquarters Lima) founded in 1879.

Persian Red Lion and Sun (headquarters Teheran) founded in 1923.
Polish Red Cross (headquarters Warsaw) founded in 1919.
Portuguese Red Cross (headquarters Lisbon) founded in 1865.
Rumanian Red Cross (headquarters Bucharest) founded in 1876.
Serb-Croat and Slovene Red Cross (headquarters Belgrade) founded in 1876.
Salvadorian Red Cross (headquarters San Salvador) founded in 1885.
Siamese Red Cross (headquarters Bangkok) founded in 1893.
South African Red Cross (headquarters Johannesburg) founded in 1913.
Swedish Red Cross (headquarters Stockholm) founded in 1865.
Swiss Red Cross (headquarters Berne) founded in 1866.
Turkish Red Crescent (headquarters Angora) founded in 1868.
U.S.S.R., Alliance of Red Cross societies and Red Crescent societies of, (headquarters Moscow) founded in 1925.
(This alliance was recognized as succeeding to the rights and responsibilities of the Russian Red Cross which was eclipsed by the Russian revolution. It comprises the following constituent societies:
Armenian Red Cross [headquarters Erivan] founded in 1920.
Azerbaijan Red Crescent [headquarters Baku] founded in 1923.
Georgian Red Cross [headquarters Tiflis] founded in 1918.
Russian Red Cross [headquarters Moscow] founded in 1867, reorganized 1918.
White Russian Red Cross [headquarters Minsk] founded in 1921.
Turkmenistan Red Crescent [headquarters Poltoratzk] founded in 1926.
Ukrainian Red Cross [headquarters Kharkov] founded in 1918.
Uzbekistan Red Crescent [headquarters Samarkand] founded in 1925.)
Uruguayan Red Cross (headquarters Montevideo) founded in 1897.
Venezuelan Red Cross (headquarters Caracas) founded in 1895.

In the course of years, a few societies have dropped out of existence, others have revised their constitutions, and others again have federated into a single society, following political changes.

The membership of certain societies is very large. In 1927, the American Red Cross had three million senior and six million junior members; the Japanese Red Cross two and a half million seniors and a million juniors; adult members of the German Red Cross numbered 1,252,000; and the membership of the Red Cross societies of the British empire 500,000 persons of all ages.

War Work.—The discharge by national societies of their primary duty as auxiliaries to the Army medical service began very early. The first opportunity for the relief of the wounded by Red Cross societies occurred in the Dano-Prussian War of 1864. In the Austro-German War of 1866, the Franco-German War of 1870, the Russo-Japanese War of 1904 and the Balkan Wars of 1912, the Red Cross societies of the belligerent countries provided ambulances, hospitals and medical and nursing personnel to the combatant forces.

Successive Colonial wars also involved a number of national societies in the obligation of providing special personnel and equipment adapted for work in tropical climates. The World War naturally led to the organization of Red Cross activity on a tremendous scale. The American Red Cross, for example, mobilized 23,000 nurses, 55,000 nurses' aids and 6,000,000 voluntary helpers, and set up canteens, hospitals, etc., wherever American troops were engaged or in training. The British Red Cross, working in close collaboration with the Order of St. John of Jerusalem and the dominion societies, provided trained nurses, voluntary aid detachments, ambulances and hospitals behind the French front, in England and in Malta, as well as in Egypt, Palestine, Corfu and Mesopotamia. Motor ambulance convoys were organized by the British Red Cross for the evacuation of the wounded, in addition to ambulance trains and (in Mesopotamia) motor ambulance launches. Material and personnel were also provided by the society for hospital ships in the Channel, in the Mediterranean and elsewhere. Similar energy was shown by the Red Cross societies of the other belligerent countries, notably the French, German, Belgian, Italian, Austro-Hungarian, Russian, Serbian and Turkish societies. The Red Cross societies of neutral countries (Switzerland, Holland, Sweden, Denmark, Norway and Spain) were also active in providing assistance to prisoners of war, hospital facilities for serious cases of wounds and sickness, and food supplies for the populations of occupied territories. Some of the latter were also evacuated into neutral territory.

Post-war Work.—The extent of the work done by the national societies during the war naturally raised their prestige and gave them a recognized place in the affections of the public. The widening of the scope of Red Cross action was a natural result of this and the societies, following the cessation of hostilities, assumed fresh responsibilities which they have shown themselves able to discharge, thanks to their large membership, to the resources at their command, and to the reserves of material at their disposal. The present activities of Red Cross societies may be summarized as follows:—

(*a*) Activities aimed at relieving sufferings consequent on the war:

Training of disabled men (establishment of orthopaedic clinics and mechano-therapic institutes, provision of artificial limbs, convalescent homes and special workshops for the disabled).

Assistance to ex-service men, war widows and orphans.

Homes for the permanently disabled. (The Star and Garter Home, Richmond, founded and endowed with the assistance of the British Red Cross is an outstanding example.)

Assistance to the population of devastated regions. (The French Red Cross has established in the old battle area and in the liberated territories, dispensaries, child welfare centres, milk stations, and relief has been supplied to more than 3,000 French villages by the American Red Cross.)

During the famines and epidemics in central Europe in the five years immediately following the armistice, Red Cross societies supplied the countries affected with food and medical stores and sent in doctors and ambulance personnel. In a number of countries (particularly Belgium, Italy, Japan, the Netherlands and the United States) emergency relief work has been brought to a high state of perfection. The Red Cross societies of these countries have a very complete system for setting in motion at short notice relief detachments fully equipped with food, transport, tents and medical stores, for purposes of relief in case of earthquakes, fires, floods, etc.

(*b*) Main present activities:

Permanent Hospitals. National Red Cross societies in certain countries maintain general hospitals (such as the Japanese Red Cross hospital at Tokyo, the Netherlands Red Cross hospital at The Hague and the German Red Cross hospital at Cassel). They also maintain specialized institutions: Clinics for surgical cases, for children, for skin diseases, for affections of the ear, nose and throat, and for maternity cases. Nursing homes, homes for mental cases and hospitals for infectious diseases are also maintained by the Red Cross. Tuberculosis cases are treated in sanatoria, which have been built on suitable sites and provided with facilities for air and sun treatment. Instances of this work are to be found in the British empire, in France, Germany, Italy, the United States and the U.S.S.R. The Belgian Red Cross among others has set up a radium institute and provides facilities for radium treatment of cancer.

In countries liable to malaria and to tropical and epidemic diseases, special hospitals have been set up by the Red Cross. Thus the Italian Red Cross maintains malaria hospitals, the Georgian Red Cross at Tiflis an Institute of Tropical Medicine, the Ukrainian Red Cross typhus hospitals, the Chinese Red Cross at Shanghai a hospital for summer diseases. Leper asylums are also maintained by certain societies. In a number of cases, national Red Cross societies have assisted in the establishment of quarantine stations for travellers or emigrants.

Other societies again possess scientific research institutes and laboratories for the manufacture of serum in connection with hospitals. The Siamese Red Cross maintains a regular service for the administration of anti-snake bite serum.

Hospital social service has been organized by the Red Cross in Great Britain, France and the United States, including the organization of hospital libraries and the arrangement of lectures, concerts, theatricals and cinematograph displays for patients.

Dispensaries and Diagnosis.—Many examples might be quoted of arrangements made under Red Cross auspices for the examination and treatment of out-patients and the supply of medicine to indigent patients. In the far north, where distances are great, communications slow and medical assistance had hitherto been unobtainable, the Canadian and Finnish Red Cross societies have

established outposts with nurses in charge, where advice and treatment can be obtained. In many cities, ambulance stations have been established to deal with street accidents.

Mobile Hospitals and Ambulances.—Flying ambulances are of the utmost value in case of disasters or epidemics and such ambulances are maintained by many societies. The Italian Red Cross maintains complete mobile hospitals in tent form, including wards, pharmacies, operating theatres and accommodation for the personnel, and these hospitals are regularly used with their accompanying personnel in case of severe outbreaks of malaria or seismic disturbances. The large stocks of transport material employed by the different national societies during the war have been largely adapted to peace-time requirements; in particular, motor ambulances are freely used for the transport of emergency cases to hospital. The Czechoslovak Red Cross maintains a fully equipped hospital train of 27 coaches, where patients can obtain advice and treatment in out-of-the-way parts of the country. A hospital ship, the "Viking," has been equipped by the Norwegian Red Cross for the purpose of giving treatment to sick and injured sailors in the ports and fishing stations of the far north. Air ambulances for the rapid transport of serious cases have been adopted by the Italian, Siamese, Spanish, Swedish and other societies.

Training of Nurses and Auxiliary Personnel.—The training and enrolment of nurses and of personnel specialized in ambulance work, pharmaceutical and radiological work, etc., is one of the principal functions of the Red Cross societies. Corps of volunteers for use in emergency are organized, such as the British Voluntary Aid detachments, and nursing schools have been set up in connection with Red Cross hospitals by the French, Japanese, Norwegian, Swedish and other societies. Social service and public health nursing are also rapidly growing activities.

Constitution of Medical Stocks.—Stocks of transport and material (dressings, medicines, etc.) are constituted by most national societies as a reserve for use in time of disaster or in case of epidemic outbreaks.

Popular Health Instruction.—Red Cross societies are active in the preventive side of the public health campaign. Lectures are organized, pamphlets issued and exhibitions arranged as part of the campaigns against tuberculosis, cancer, venereal diseases and alcoholism. Home nursing and care of the sick and household sanitation are also taught under Red Cross auspices.

Child Welfare.—Child welfare is an important item on the Red Cross programme and efforts are made by all national societies to reduce infantile mortality and to afford increased protection to mothers and babies. For this purpose, child welfare centres, milk stations and crêches have been organized, school hygiene is emphasized, summer colonies are arranged and preventoria established. Some societies also provide orphanages and homes for deserted children.

Junior Red Cross.—Reference has already been made to this growing activity in connection with the programme of the League of Red Cross societies (*see* p. 20).

Co-operation with Other Social Agencies.—Besides collaborating with Government services, the national Red Cross societies are in constant contact with other humanitarian institutions, such as the Order of St. John of Jerusalem, the Sovereign Order of Malta, Nursing and Samaritan associations, Health and Medical societies, Social Service groups and organizations for assisting travellers and emigrants, etc.

The close relationship maintained between the central committees of the different national societies and the contact established between Red Cross members in different countries is resulting in continuously growing international co-operation in Red Cross work throughout the world. An interesting illustration is the agreement signed in 1924 between the Italian and the American Red Cross societies, by which it was agreed that American Red Cross members travelling in Italy, or Italian Red Cross members travelling in the United States, might count upon Red Cross assistance. The 12th International Red Cross conference in 1925, basing itself upon this precedent, expressed the hope that an international identity card might be established for the use of Red Cross members in any country, when abroad.

INTERNATIONAL RED CROSS CONFERENCES

International Red Cross conferences meet at regular intervals and include representatives of the Governments signatory to the Geneva Convention, together with representatives of national Red Cross societies and of the International committee of Geneva. The first of these conferences met in Paris, in 1867; the second in Berlin, in 1869; the third in Geneva, in 1884; the fourth at Karlsruhe, in 1887; the fifth in Rome, in 1892; the sixth in Vienna, in 1897; the seventh in St. Petersburg, in 1902; the eighth in London, in 1907; and the ninth in Washington, in 1912; the 10th, 11th and 12th international conferences, like the third, were held in Geneva, it being considered that after the World War, as after the war of 1870, advantage was to be derived from bringing representatives of the different Red Cross societies together in an atmosphere of perfect neutrality. Peace conditions having now resumed, the International Red Cross conferences will again meet each time in a different capital; the 13th international conference was convoked to meet at The Hague in Oct. 1928. These conferences provide the opportunity for the systematic development of the original Red Cross programme. The resolutions of the international conferences constitute the basis of the activities of the International Red Cross committee, and other matters dealt with have included the relations between national societies and their respective Governments, the activities of national societies in peace and war and the functions of the Red Cross in maritime warfare. Attention has also been given by the conferences to questions of personnel and material, hospitals, prisoners of war and the organization of disaster relief. Resolutions and recommendations have been drawn up regarding the position of non-combatants in enemy territory, chemical warfare, the reduction of the number of casualties reported "missing" in wartime, the protection of air ambulances against attack, the use of the Red Cross emblem, civil war, the limitation of war, and other questions. (E. CL.)

AMERICA

The American Red Cross was founded in 1881 under the name American Association of the Red Cross, and was incorporated in 1905 as The American National Red Cross. The president of the United States became its president, and the war department its auditor. Early in the World War the Red Cross offered through the State department the aid of its trained personnel and contributions of hospital supplies to every belligerent country. This offer was accepted by almost all belligerents. A public appeal was made for funds, and soon large quantities of hospital supplies and about 200 nurses were sent to England, Belgium, France, Germany, Austria, Serbia and Russia. Seventy-one physicians and surgeons were also sent, and a special sanitary commission went to Siberia to fight the typhus plague there. The value of relief supplies sent to Europe by the Red Cross before the United States entered the war was more than $1,500,000, of which about $350,000 worth went to Germany and Austria. In May 1917 after America's entry into the war, President Wilson appointed a special Red Cross war council under H. P. Davison to direct the activities of the organization during the war. A popular campaign for a special war fund realized $100,000,000 in a week. The service was reorganized and quickly expanded from 500,000 members in 500 chapters to over 16,000,000 members. A further week's drive in May 1918 realized $170,000,000, and the grand total, 1917–18, exceeded $400,000,000.

The American Red Cross recruited, organized and equipped hospitals and ambulance units, assisted in the care of the sick and wounded in emergencies, and provided nurses for the army and navy. It supplied comforts, clothing, medical supplies and surgical dressings, ran canteens, assisted the families of soldiers and sailors, photographed graves, etc. It supported 50 base hospital units, 40 overseas ambulance companies, over 23,000 trained nurses, a women's volunteer motor corps of 14,000 members, 92 convalescent homes in the training and embarkation camps, 130 canteens, 24 military hospitals and 12 convalescent hospitals in France, 33 canteens in Italy, 28 military hospitals and 82 canteens in Bel-

gium. The "civilian relief abroad" to the European populations was on a vast scale. $1,000,000 a month were spent on relief to French and Belgian refugees in France, including help to over 150 national and local French organizations. Over 30,000 tuberculosis patients were helped and a large children's welfare movement run. Substantial assistance was given in Russia; also in Belgium, Italy, Rumania, Serbia and Greece. The relief expenses included $28,978,000 in America, $57,207,000 in France, $63,841,000 elsewhere overseas. A total of 101,000 tons of relief supplies were sent overseas; 3,780 French and over 1,500 Italian hospitals assisted. The value of the relief articles produced by volunteer workers during the war was estimated at nearly $100,000,000. (G. A.)

At the close of the war a peace-time programme was inaugurated, continuing relief work in destitute European countries, providing aid for disabled veterans and ex-service men and enlarging the scope of the various Red Cross services. Outstanding in this programme has been the comprehensive development of a disaster relief service which makes possible an instant response to calls for help when fire, flood, storm or famine occurs. Not only has aid been given in hundreds of disasters in this country, with the Red Cross in complete charge of the relief, but financial aid has been given to scores of foreign countries suffering disasters which they were unable to handle alone. Authorization for this work is given in the congressional charter of 1905 which stipulates that the organization, in addition to furnishing volunteer aid to the sick and wounded of armies in the time of war, shall "continue and carry on a system of national and international relief in time of peace and to apply the same in mitigating the suffering caused by pestilence, famine, fire, floods and other great national calamities, and to devise and carry on measures for preventing the same." It is primarily for the purpose of maintaining an organization able to move instantly to the relief of disaster-stricken communities that the Red Cross keeps its executive machine well oiled and strengthened by a diversified and valuable programme in other fields during times when no great disaster is being suffered. These services include a public health nursing programme; instructions in first aid and life-saving; a nutrition service; the Junior Red Cross; volunteer nursing and war service. In times of national disaster the personnel of all of these divisions directs its attention to the relief of the sufferers.

A far-flung network of Red Cross chapters, numbering in 1928 more than 3,500 in the various States and insular possessions, is one of the organization's unique qualifications for disaster service. Most of these chapters maintain their own disaster committees and have at their finger-tips information as to buildings available for hospital use in emergencies, lists of supply sources and similar data. In the event of a disaster the nearest chapter goes immediately to the aid of the stricken community, wiring national headquarters in Washington or the branch offices in St. Louis and San Francisco what the extent of the damage is and whether national aid will be required. The quick response of the chapters not infrequently means the saving of hundreds of lives and the prevention of unnecessary suffering.

Outstanding among disasters in which the Red Cross has administered relief have been the northern Ohio tornado of 1924, the mid-western tornado of 1925, the Florida hurricane of 1926 and the Mississippi river valley flood of 1927. The greatest foreign disaster in which aid was given by the organization was the Japanese earthquake and fire which razed Tokyo and Yokohama in 1923. Sufferers in hundreds of other disasters were rehabilitated by the Red Cross.

The nursing service of the organization has an enrolment of approximately 45,000 women who serve as a reserve and source of supply for the army, navy, public health service, U.S. Veterans' bureau and for duty in emergencies. More than 27,000 of these are listed as active. Approximately 750 public health nurses are being supported entirely or in part by the Red Cross, working particularly in the crowded sections of large cities and in isolated rural and mountain sections. Under the direction of national headquarters the Red Cross has trained more than 134,000 men, women and youths in life-saving methods, thereby reducing drowning fatalities and reducing also the hazards of water sports. First aid instruction also is given, an average of more than 20,000 persons passing the rigid tests each year. A first aid instruction car is a valuable asset in disseminating information about the care of accident victims and is in continuous operation over the various railways systems of this country. The nutrition service gives instruction in dietetics to thousands.

The American Junior Red Cross, designed to promote a spirit of friendship and understanding among the children of all nations, has over 6,500,000 members in elementary and high schools throughout the United States and its insular and foreign possessions, is part of a movement world-wide in scope, and boasts a total of more than 10,000,000 members in 46 countries.

Volunteer workers for the Red Cross engage in the making of garments, surgical dressings, and braille for the blind, in bringing cheer to ex-service men in the hospitals through their hostess service, maintain motor corps for work in emergencies and furnish personnel for use in chapter offices, for service in disaster relief and similar enterprises. It has been estimated that approximately 90% of the total number of regular Red Cross workers serve as volunteers, without any compensation. The Red Cross is supported by the annual subscriptions of its members. The present membership is slightly more than 4,000,000. (D. Gr.)

RED-DEER (*Cervus elaphus*), the male of which, the stag, *par excellence*, reaches a height of 4ft. 6in. at the shoulder. The antlers are rounded, possessing bez-tines and in well-developed animals at least 12 points, the record number for a British wild specimen being 20, though an ancient Irish skull was found bearing 34 and a park specimen had 39. The tail is rather long and the coat is spotted in the young and occasionally even in the adult. The males, which alone bear antlers, often have a "mane" on the throat, and in the breeding season utter a roaring cry. There are numerous local races of the red-deer, which inhabit Europe, northern Africa, Asia Minor and north Persia; the species has been successfully introduced into New Zealand. Typically a

woodland animal, the red-deer in Britain is now confined to open mountain-sides in the highlands of Scotland, Exmoor and a few other localities, and to parks; as a result, there has been a decided decline in the size and condition of the Scottish animals, which cannot compare with those from the Continent. (*See* DEER.)

REDDITCH, a town in Worcestershire, England, situated near the Warwickshire border, 15½ m. S. of Birmingham by the L.M.S. railway. Pop. of urban district (1921) 16,231. It is the centre of a district producing needles and fish-hooks. There are also motor-engineering works.

REDESDALE, JOHN FREEMAN-MITFORD, BARON (1748–1830), English lawyer and politician, younger son of John Mitford (d. 1761) and brother of the historian William Mitford, was born in London on Aug. 18, 1748. Having become a barrister of the Inner Temple in 1777, he wrote *A Treatise on the Pleadings in Suits in the Court of Chancery by English Bill,* which has been reprinted several times. In 1788 Mitford became M.P. for Beeralston in Devon, and in 1791 he introduced the important bill for the relief of Roman Catholics, which was passed into law. In 1793 he became solicitor-general, becoming attorney-general six years later, when he sat for East Looe, in Cornwall. In Feb. 1801 he was chosen speaker of the House of Commons. A year later, he was appointed lord chancellor of Ireland with the title of Baron Redesdale. Being an outspoken opponent of Roman Catholic emancipation, Redesdale was unpopular in Ireland. In Feb. 1806 he was dismissed on the formation of the ministry of Fox and Grenville. Although Redesdale declined to return to official life, he was an active member of the House of Lords both on its political and its judicial sides. He died on Jan. 16, 1830.

See O. J. Burke, *History of the Lord Chancellors of Ireland* (Dublin, 1879); J. R. O'Flanagan, *Lives of the Lord Chancellors of Ireland* (1870); Sir J. Barrington, *Personal Sketches of His Own Times* (1869); Sir S. E. Brydges, *Autobiography* (1834); and C. Abbot, Lord Colchester, *Diary and Correspondence* (1861).

REDFERN: *see* SYDNEY.

RED INDIANS: *see* NORTH AMERICA: *Ethnology.*

RED JACKET (Sagoyewatha—"he who keeps them awake") (*c.* 1751–1830) was a Seneca Indian chief born near Geneva, N.Y., about 1751. He was an eloquent orator—whence his Indian name—and possessed considerable influence over his people. He fought for the British during the Revolution and because of his ability as a runner was a favourite among the officers, one of whom presented him with a heavily embroidered red coat. This made him conspicuous among his people and he was henceforth known as Red Jacket. He first appeared as a conspicuous figure when he made a notable speech in opposition to the treaty which was signed at Ft. Stanwix in 1784 by the United States and the Six Nations. In 1792 he went to Philadelphia, then the capital, to conclude a treaty of friendship with the United States, and President Washington presented him with a medal. Under his leadership the Senecas allied themselves with the Americans against the British in the War of 1812. Red Jacket understood the whites well and became more and more hostile to them as he realized their overwhelming power. "You are a kind-hearted people, seeking your own advantages," he said in one of his speeches. He tried to consolidate his people and preserve their ancient ways and rites, but by his stand only lost his leadership. He died in Seneca village, N.Y., on Jan. 20, 1830.

See J. Hubbard, *An Account of Sagoyewatha* (1886); and W. S. Stone, *The Life and Times of Sagoyewatha* (1866).

REDLANDS, a city of San Bernardino county, California, U.S.A., 67 m. E. of Los Angeles, at the head of the fertile San Bernardino valley. It has an airport, and is served by the Pacific Electric, the Santa Fé and the Southern Pacific railways, and by motor-coach lines in all directions. Pop. 9,571 in 1920 (83% native white); estimated locally at 18,000 in 1928. The city lies at an altitude of 1,356–1,850 ft., surrounded on three sides by peaks over 10,000 ft. high (Mounts San Jacinto, San Antonio or Old Baldy, San Bernardino and San Gorgonio), in the midst of the largest orange-growing district of the world. From 4,500 to 6,000 carloads of citrus fruit are packed and shipped from Redlands each season, and the canning of fruits is one of the city's chief industries. The University of Redlands (Baptist; opened in 1907) has an enrolment of 700. A settlement called Lugonia was established here in 1874, but the present city was founded in 1887, by New Englanders, and incorporated in 1888. In 1928 the assessed valuation of property was $15,744,778. It is governed by an elected board of trustees.

REDLICH, JOSEPH (1869–), Austrian historian and politician, was born in Göding, Moravia, on June 18, 1869. He studied jurisprudence and history in Vienna, travelled extensively, especially in England, and in 1901 published his first work, *Die englische Lokalverwaltung* (*Local Government in England,* 1904). He afterwards became Professor at Vienna University, and sat in the Austrian parliament till 1911 as deputy for his birthplace. Both in the Austrian parliament in Vienna and the Moravian diet he did much to further the idea of an understanding between the German and Czech races. In 1905 he published another study of English political life: *Recht und Technik des englischen Parlamentarismus* (1905), Eng. trans., *The Procedure of the House of Commons,* 3 vols. (1907), a standard work on the subject and indispensable to the student. During the World War he was politically active, and in 1918 was appointed minister of Finance in the Lammasch Cabinet. He then retired from active politics, to produce *Das oesterreichische Staats- und Rechtsproblem* (vol. 1 1920, vol. 2 1926), a history of Austrian domestic policy from 1848 onward. His other works include *Das Wesen der oesterreichischen Kommunalverfassung* (1910); *The Common Law and the Case Method in American University Law Schools* (1914); *Oesterreichische Regierung und Verwaltung im Weltkriege* (English and German, 1925) and a biography, *Franz Joseph von Oesterreich* (1928). Redlich's attitude was usually rather that of a student of political theory and practice than of a pure historian, and his works were apt to be too voluminous to be easily read; but they were founded on encyclopaedic knowledge, most carefully presented, and were exhaustive.

RED LODGE, a city of southern Montana, U.S.A., 10 m. from the Wyoming State line; the county seat of Carbon county. It is served by the Northern Pacific railway. Pop. (1920) 4,515 (34% foreign-born white). It is the centre of one of the principal coal-mining regions of the State, and there are also gold and silver mines in the vicinity. The Beartooth National Forest lies a few miles to the west.

REDMAYNE, SIR RICHARD AUGUSTINE STUDDERT (1865–), K.C.B. (1914), was born at Gateshead-upon-Tyne, on July 22, 1865, and educated privately and at the Durham College of Science, Newcastle. In 1883 he became undermanager at a colliery firm in Durham, and eight years later went to South Africa. On his return in 1893 he was appointed manager of the Seaton Delaval collieries, Northumberland (1893–1902). He then obtained an appointment at Birmingham university, as professor of mining. He acted as chairman on numerous Government committees on questions affecting the mines, and in 1908 was appointed chief inspector of mines, a post which he held until 1920. From 1916 he held also the post of assistant controller of coal mines. From 1918 to 1925 he was chairman and governor of the Imperial Mineral Resources bureau. He is the author of many official reports on mining, and one of the first authorities on the subject.

REDMOND, JOHN EDWARD (1856–1918), Irish politician, son of W. A. Redmond, M.P., was born at Ballytrent. He was educated at Trinity college, Dublin, and was called to the bar at Gray's Inn in 1886, and subsequently to the Irish bar, though he never practised. He was a clerk in the vote office of the House of Commons before he entered parliament in 1881 as member for New Ross. From 1885 to 1891 he represented North Wexford. As party whip he rendered great service to the Irish members by his thorough grasp of the procedure of the House. At the time of the rupture of the Irish party consequent on the Parnell scandals, Redmond was the most eloquent member of the minority who continued to recognize his leadership, and in 1891 he became the accredited leader of the Parnellites. In 1900 the two nationalist parties were amalgamated under his leadership. He contested Cork unsuccessfully in 1891, but was elected for Waterford, where he was re-elected in 1906. (For the political

events under his leadership of the Irish parliamentary party up to 1910, *see* IRELAND: *History;* ENGLISH HISTORY, etc.).

Redmond obtained for the first time a position of real power in parliament after the general election in Jan. 1910. Though he had amalgamated the two Irish Nationalist parties under his own lead in 1900, he had never hitherto been able, owing to the large Unionist majority of 1900 and the Liberal majority of 1906, to hold that balance of power in the House of Commons which had proved such a formidable weapon in the hands first of O'Connell and then of Parnell. But the reduction of the Liberal forces in Jan. 1910 made it impossible that Asquith's Government should long continue unless it found favour with Redmond.

The first use which he made of this new authority was to insist that Lloyd George's famous budget of 1909, on which the dissolution had turned, should be postponed till after the constitutional resolutions directed against the House of Lords—his one object being to remove the veto of the Upper House, which was the main barrier against Home Rule. This order of procedure was also demanded by the Labour party and by the Radicals; and the Government complied. But Redmond pressed further for an assurance that the royal prerogative would be at the prime minister's disposal to overbear any rejection by the Lords of the veto resolutions. He was impatient at the constitutional conference called in the summer at the beginning of King George's reign to endeavour to discover a solution by consent, and went to America to secure sympathy and funds. The conference having broken down, he conducted a strenuous campaign on behalf of the ministerial programme for the second general election of the year, in spite of a harassing movement on his flank by a small party of independent Nationalists under O'Brien and Healy, who accused him of having sold the Irish vote to the government.

When the result of the polling had confirmed Redmond in his tenure of the balance of parliamentary power, he forwarded the progress of the Parliament bill in 1911 by the steady vote of his party. In the autumn he was regularly consulted on the details of the forthcoming Home Rule bill, and when the bill was introduced, in April 1912, he procured its enthusiastic acceptance from a nationalist convention in Ireland. His speeches during its passage through parliament were, on the whole, moderate; he disclaimed separation but denounced any attempt to take Ulster out of the bill as a mutilation of Ireland. In token of the union of feeling between Nationalists and Liberals, he attended the meeting of the National Liberal Federation at Nottingham in Nov. 1912, and spoke for the first time on the same platform as Asquith. When the determined attitude of Ulster began to suggest to the Liberals the advisability of compromise, Redmond was very loth to agree, denouncing the Unionists and Ulster as engaged in "a gigantic game of bluff and blackmail." He insisted that Asquith's county option scheme was the extreme limit of concession. He was being pressed in Ireland by the rising power of Sinn Feiners and other extremists who had raised, in reply to Ulster, a great body of 100,000 nationalist volunteers, over whom Redmond only obtained control in June 1914 after a sharp struggle. Nevertheless he took part, at the end of July in the abortive Buckingham Palace Conference.

Then came the World War, and in the debate succeeding Sir E. Grey's famous declaration on Bank Holiday, Aug. 3, Redmond created a profound sensation by a speech in which he declared that the events of recent years had completely altered the Nationalist feeling towards Great Britain. The Government, he said, might withdraw its troops from Ireland, whose coasts would be defended by her own sons, Nationalist volunteers joining with Ulster volunteers in the task. This generous attitude was met by the decision of the Government to pass the Home Rule bill into law, suspending its operation till after the war. Redmond took an active part in promoting recruiting in Ireland, and stood on the platform in Dublin Mansion House on Sept. 25 by the side of the prime minister and the lord lieutenant. Unfortunately, his efforts were only moderately successful, but he refused Asquith's offer to join the first Coalition Government, and he successfully opposed all attempts to apply conscription to Ireland. It was a stunning blow to him when the smouldering dissatisfaction of southern Ireland broke out into a blaze in the Dublin rebellion of Easter 1916. He expressed in the House of Commons his detestation of the crime, and lent his assistance to the attempt which was made by the Government in the summer through Lloyd George to arrange an agreed settlement of the Irish question.

But the effort failed; Duke, a Unionist, was appointed chief secretary; and Redmond treated the whole transaction as a fresh outrage on Ireland, moving on Oct. 18 a resolution (which was, of course, rejected) charging ministers with maintaining a system of Government in that country inconsistent with the principles for which the Allies were fighting in Europe. Next year he threatened a return of his party to the old obstructionist opposition; but when in May 1917 Lloyd George, as prime minister, suggested an Irish convention to produce a scheme of self-government, Redmond agreed; and in the convention he played a conciliatory part. During its sittings, however, his health failed. He died of heart failure in London on March 6, 1918.

See I. G. Redmond Howard, *John Redmond* (1910); *Home Rule: Speeches of John Redmond, M.P.* edit. by R. Barry O'Brien (1919); S. Gwyn, *John Redmond's Last Years* (1919).

REDMOND, WILLIAM HOEY KEARNEY (1861–1917), younger brother of John Redmond (*q.v.*), intended, as a young man, to adopt the army as his profession, and in 1881 he was a lieutenant in the Co. Wexford militia battalion of the Royal Irish regiment. But he resigned his commission to take part in the Land League movement and was imprisoned as a "suspect" in Kilmainham. He was returned for Wexford borough in 1883, and sat in parliament, though for different constituencies, from that time till his death. He was of an ardent and ebullient temper, which resulted in his spending three months in Wexford gaol in 1888 for inciting, at an eviction, to resistance to the sheriff, and in many agitated scenes at different times in the House of Commons, where, however, he was personally very popular. Like his brother, in the Nationalist split he adhered to Parnell, and, also like his brother, on the outbreak of the World War he instantly recognized the duty of Ireland to fling herself into it on the side of the Allies. Though 53 years old, he joined at once the Irish division, receiving a commission in the Royal Irish regiment. He was promoted major for services at the front and mentioned in dispatches. In his intervals of service he made two thrilling speeches in the House of Commons, advocating conciliation, and a new start, between England and Ireland. He died of wounds in France on June 7, 1917.

See Memorial Volume, *Major William Redmond* (1917); W. H. K. Redmond, *Trench Pictures from France* (1917); T. P. O'Connor, *The Parnell Movement* (1886).

RED OAK, a city of south-western Iowa, U.S.A., 50 m. S.E. of Council Bluffs, on the Nishnabotna river, Federal highway 34, and the Burlington (railway) Route; the county seat of Montgomery county. Pop. (1925 State census) 5,686. A large part of all the calendars used in the United States are made here. Stock-feeds, flour and iron are also important manufactures. The city was founded about 1855 and incorporated in 1869. It has a commission-manager form of government.

REDON, a town of western France, capital of an *arrondissement* in the department of Ille-et-Vilaine, 45 m. S. S.W. of Rennes by rail. Pop. (1926) 5,201. Redon grew up round a monastery founded in the 9th century. In the 14th century the abbot Jean de Tréal surrounded the town with walls, of which a portion remains. Redon stands on the right bank of the Vilaine, above the confluence of the Oust and the canal from Nantes to Brest. The church of St. Sauveur, a former abbey, has a square Romanesque central tower with rounded angles. A fine 14th century tower with a stone spire stands isolated from the church, from which it was separated by fire in 1782. The 13th century choir, with ambulatory and radiating chapels, is notable.

REDONDA, an island in the British West Indies. It is a dependency of Antigua, and lies 25 m. S.W. of it, in 25° 6′ N. and 61° 35′ W. Pop. (1901) 120. It is a rocky mountain, rising abruptly from the sea to a height of 1,000 ft., and has an area of ½ sq.m. About 7,000 tons of phosphate of alumina are exported

every year to the United States.

REDONDO BEACH, a city of Los Angeles county, California, U.S.A., on the Pacific ocean, 19 m. S.W. of Los Angeles and 10 m. W. of the Los Angeles and Long Beach harbour. It is served by the Pacific Electric, the Santa Fe and the Southern Pacific railways. Pop. 4,913 in 1920; estimated locally at over 12,000 in 1928. In a natural amphitheatre facing the ocean the city slopes gently upward from its silvery crescent-shaped beach to an elevation of 250 ft., with Los Angeles and the San Gabriel mountains in the background. It is a pleasure and health resort, and a residential centre for workers in the adjacent oil-fields and industrial districts. The city owns a mile of the water front, including Moonstone Beach. There is a large indoor salt-water plunge (70 by 218 ft.). The city was incorporated in 1892.

REDPOLL, the name given to several birds of the finch family (*Fringillidae*), allied to the linnet (*q.v.*), and possessing a reddish head. The best known is the lesser redpoll (*Carduelis linaria*). The mealy redpoll is a subspecies with a more northern range, visiting England in the winter. The type ranges over the whole of the north temperate zone. There are three additional subspecies in America, but these rarely reach the United States.

RED RIVER, the name of two American rivers, one emptying into the Mississippi near its mouth, and the other emptying into Lake Winnipeg.

1. The Red river, sometimes called the Red River of Louisiana, is the southernmost of the large tributaries of the Mississippi. It rises in northern Texas, in the northern part of the High Plains, or Llano Estacado, flows east by south in Texas, between Texas and Oklahoma, and to Fulton, in south-western Arkansas, there turns south-east and continues in a general south-easterly direction through Louisiana to the bank of the Mississippi, where it discharges partly into the Mississippi and partly into the Atchafalaya. Its length is estimated at 1,200 m. or more; its drainage basin has an area of at least 90,000 sq.m.; and its discharge ranges from 3,500 cu.ft. to 180,000 cu.ft. per second. Its middle and lower course is laden with a reddish silt from which it takes its name. From an elevation on the High Plains of about 2,450 ft., the river plunges into a canyon which is about 60 m. long and has nearly perpendicular walls of sandstone and gypsum formation 500 to 800 ft. high. Immediately below the canyon the river spreads out over a broad and sandy bed and flows for about 500 m. through a semi-arid plain. It narrows on entering the alluvial bottom lands, through which it pursues a sluggish and meandering course for the last 600 m. A shifting channel, deposits of silt and fallen trees have always hindered navigation. In 1828 the trees which the river had felled formed the great "Red River raft" extending from Loggy Bayou, 65 m. below Shreveport, Louisiana, to Hurricane Bluffs, 27 m. above Shreveport. Congress began in that year to make appropriations for the removal of the raft, and by 1841 Henry M. Shreve had opened a channel. The river was neglected from 1857 to 1872 and another raft, 32 m. in length, formed above Shreveport. A channel was opened through this in 1872–73, and the complete removal of the obstruction a few years later so improved the drainage that a large tract of waste land was reclaimed. In its course through Louisiana the river has built up a flood-plain with silt deposits more rapidly than its tributaries, with the result that numerous lakes and bayous have been formed on either side, and Cypress has been so flooded that boats ply between Shreveport, Louisiana, and Jefferson, Texas, 66 m. apart. The main river is navigable for small draught boats from the mouth to Fulton, Ark., a distance of 508·6 m.; however, there is little commerce above the mouth of the Black.

During the Civil War, in March and April 1864, Major-General Nathaniel P. Banks conducted a combined military and naval expedition up the Red river in an attempt to open a Federal highway to Texas, but on April 8, the vanguard of his army was repulsed with heavy loss at Sabine Cross-Roads by the Confederates under Lieut.-Gen. Richard Taylor and the expedition was abandoned; the gunboats commanded by Rear Admiral D. D. Porter were held above Alexandria by the lowness of the river, but it was flooded by a hurriedly built dam, and they escaped.

See R. B. Marcy and G. B. McClellan, *Exploration of the Red River of Louisiana* (Washington, 1853), and the annual *Reports* of the Chief of Engineers of the U.S. Army.

2. The Red river, commonly called the Red River of the North, rises in the lake region of western Minnesota, not far from the headwaters of the Mississippi, flows north between Minnesota and North Dakota, continues northward through the Canadian province of Manitoba, and discharges into Lake Winnipeg. It has cut a gorge 20 to 50 ft. deep through clay deposits throughout the greater part of its course; it drains a region that is famous for the production of wheat; and much water-power has been developed on its tributaries.

RED RIVER SETTLEMENT, a Scottish colony founded in 1811 near the present city of Winnipeg by a philanthropic Scottish nobleman, Lord Selkirk, who at that time controlled the Hudson's Bay Company. Quarrels soon arose with the French and half-breed employees of the North-West Fur Company, and were fostered by its officials. On June 19 1816, in a fight between the rivals, Governor Semple of the Hudson Bay Company and 20 of his 27 attendants were killed, an affair known as the Battle of Seven Oaks. New settlers were sent by Selkirk, and founded the village of Kildonan, now part of Winnipeg. In 1821 the rival companies united, and in 1836 repurchased from Selkirk's heirs all rights to the territory. In 1821 and in 1835 two forts, known as Lower and Upper Fort Garry, were built to command the junction of the Red and Assiniboine rivers. The purchase in 1869 of the territorial rights of the company by the Dominion of Canada led to a rebellion, and the setting up of a provisional government under Louis Riel, which was dispersed by a force of British regulars under Colonel (later Lord) Wolseley.

BIBLIOGRAPHY.—*See* CANADA: *History;* also George Bryce, *Remarkable History of the Hudson's Bay Company* (1900).

REDRUTH, a market town in Cornwall, England, 17 m. E.N.E. of Penzance, on the G.W. railway. Pop. of urban district (1921) 9,916. It lies high, on the northward slope of the central elevation of the county, with bare rocky moors to the south. It is the chief tin-mining town in Cornwall, and the bulk of the population is engaged in the mines or at the numerous tin-streaming works. The parish church of St. Uny, of which only the tower is ancient (Perpendicular), stands outside the town to the west, at the foot of Carn Brea. On the summit of this hill, besides a small ancient castle, various prehistoric remains are traceable. A large quantity of the tin is sold by public auction at the mining exchange, the sales being known as tin-ticketings. There are manufactures of safety fuses, breweries, tanning, iron foundries and railway works, and near by are numerous stone quarries.

RED SEA, a narrow strip of water extending south-south-east from Suez to the Strait of Bab el Mandeb in a nearly straight line, and separating the coasts of Arabia from those of Egypt, Nubia and Abyssinia. Its total length is about 1,200 m., and its breadth varies from about 250 m. in the southern half to 130 m. in 27° 45′ N., where it divides into two parts, the Gulf of Suez and the Gulf of Aqaba, separated from each other by the peninsula of Sinai. Structurally, the Red sea is part of a great rift-valley system forming one of the most marked features of the earth's crust. The rift valley of the Jordan and the Dead sea is continued southward by the Wadi el Araba, and its submerged southern section gives the Gulf of Aqaba. This well marked north-north-east to south-south-west line meets the north-north-west to south-south-east line, already marked in the Gulf of Suez, and together they form, to the south, the main basin of the Red sea. The rift may be traced still farther southward among the great African lakes.

This great structural depression is probably of Tertiary age, being let down between two ancient Archaean blocks—Arabia and North Africa. Secondary and Tertiary deposits appear on both flanks in Egypt and Arabia, while Archaean material appears at the surface in many places on the Red sea coast. These extensive earth movements were accompanied by much volcanic activity, traces of which are still evident. A group of volcanic islands occurs in 14° N., and on Jebel Teir, farther north, a volcano has only recently become extinct. The margin of the Red sea

itself consists, on the Arabian side, of a strip of low plain backed by ranges of barren hills of coral and sand formation, and here and there by mountains of considerable height. The greater elevations are for the most part formed of limestones, except in the south, where they are largely volcanic. The coasts of the Gulf of Aqaba are steep, with numerous coral reefs on both sides. On the African side there are, in the north, wide stretches of desert plain, which towards the south rise to elevated tablelands, and ultimately to the mountains of Abyssinia. The shores of the Red sea are little indented; good harbours are almost wanting in the desert regions of the north, while in the south the chief inlets are at Massawa, and at Kamaran, almost directly opposite. Coral formations are abundant; immense reefs, both barrier and fringing, skirt both coasts, often enclosing wide channels between the reef and the land.

Depths.—The mean depth of the Red sea is 267 fathoms. The Gulf of Suez is shallow, and slopes regularly down to the northern extremity of the Red sea basin, which has a maximum depth of 640 fathoms, and then over a shoal of 60 fathoms goes down to 1,200 fathoms in 22° 7′ N. The Gulf of Aqaba is separated from the Red sea by a submarine bank only 70 fathoms from the surface, and in 28° 39′ N. and 34° 43′ E. it attains the depth of 700 fathoms. South of the 1,200-fathom depression a ridge rises to 500 fathoms in the latitude of Jeddah, and, south of this again, a similar depression goes down to 1,190 fathoms. Throughout this northern part, *i.e.*, to the banks of Suakin and Farsan in 20° N., the 100-fathom line keeps to a belt of coral reef close inshore, but in lower latitudes the shallow coral region, 300 m. long and 70 to 80 m. across, extends farther and farther seaward until, in the latitude of Hodeida, the deep channel (marked by the 100-fathom line) is only 20 m. broad, all the rest of the area being dangerous to navigation, even for small vessels. In the middle of the gradually narrowing channel three depressions are known to exist; soundings in two of these are: 1,209 fathoms in 20° N. and 890 fathoms in 16° N., a little to the north of Massawa. To the north-west of the volcanic island of Zebayir the depth is less than 500 fathoms; the bottom of the channel rises to the 100-fathom line at Hanish island (also volcanic), then shoals to 45 fathoms, and sinks again, in about the latitude of Mokha, in a narrow channel which curves westward round the island of Perim (depth 170 fathoms), to lose itself in the Indian ocean. This western channel is 16 m. wide in the Strait of Bab el Mandeb; the eastern channel of the strait is 2 m. broad and 16 fathoms deep. Estimates of the total area of the Red sea vary considerably, but it may be taken at 177,030 sq.st.m. approximately, and the volume at 53,700 cb.st.m. approximately.

Meteorology.—In the northern part, down to almost 19° N., the prevailing winds are north and north-west. The middle region, to 14°–16° N., has variable winds in an area of low barometric pressure, while in the southern Red sea south-east and east winds prevail. From June to August the north-west wind blows over the entire area; in September it retreats again as far as 16° N., south of which the winds are for a time variable. In the Gulf of Suez the westerly, or "Egyptian," wind occurs frequently during winter, sometimes blowing with violence, and generally accompanied by fog and clouds of dust. Strong north-north-east winds prevail in the Gulf of Aqaba during the greater part of the year; they are weakest in April and May, sometimes giving place at that season to southerly breezes. The high temperature and great relative humidity in summer, make it a difficult region for active life.

The mean annual temperature of the surface waters near the head is 77°; it rises to 80° in about 22° N., to 84° in 16° N., and drops again to 82° at the Strait of Bab el Mandeb. Daily variations of temperature are observable to a depth of over 50 fathoms. Temperature is, on the whole, higher near the Arabian than the Egyptian side, but it everywhere diminishes with increase of depth and latitude, down to 380 fathoms from the surface; below this depth a uniform constant temperature of 70·7° is observed throughout. In the Gulf of Suez temperature is relatively low, falling rapidly from south to north. The waters of the Gulf of Aqaba are warmer towards the Arabian than the Sinai coast; a uniform temperature of 70·2° is observed at all depths below 270 fathoms.

Salinity.—The salinity of the waters is relatively great, the highest reading being 41 per mille (Gulf of Suez), and the lowest 36·5 near Perim island. The distribution is, speaking generally, the opposite to that of temperature; salinity increases from the surface downwards, and from the south northwards, and it is greater towards the western than the eastern side. This statement holds good for the Gulf of Suez, in which the water is much salter than in the open sea; but in the Gulf of Aqaba the distribution is exceedingly uniform, nowhere differing much from an average of 40 per mille.

The movements of the waters are of great irregularity and complexity, rendering navigation difficult and dangerous. Two features stand out with special distinctness; the exchange of water between the Red sea and the Indian ocean, and the tidal streams of the Gulf of Suez. From the observations of salinity it is inferred that a surface current flows inwards to the Red sea in the eastern channel of the Strait of Bab el Mandeb, while a current of very salt water flows outward to the Indian ocean, through the western channel, at a depth of 50 to 100 fathoms from the surface. In the Gulfs of Suez and Aqaba, almost the only part of the Red sea in which tidal phenomena are well developed, a sharply-defined tidal circulation is found. Elsewhere, the surface movements at least are controlled by the prevailing winds, which give rise in places to complex "transverse" currents, and near the coast are modified by the channels enclosed by the coral reefs. During the prevalence of the north and north-west winds the surface level of the northern part is depressed by as much as 2 feet.

The Red sea was important in Egyptian maritime commerce at least as early as the 2nd millennium B.C. (*see* QOSEIR, EL) and it had associations with India early in the 1st millennium B.C. Under the Arabs the Red sea was an important highway of trade with connections to India, Persia and East Africa. This sea helped to keep Islam in touch with the thinkers of the East and with the glories of the ancient world during "the dark ages" in the West; with the revolutions in shipping and movement by sea that followed "the age of discovery" the Red sea seemed to retreat into the background; but with the cutting of the Suez canal (1869) and the shortening of the route to India, Australia and the East, the Red sea not only recovered its former importance but became one of the greatest commercial highways in the world.

REDSHANK, the name of a bird, *Tringa totanus*, so called from the colour of its long legs. In suitable localities it is abundant throughout the greater part of Europe and Asia, retiring southward for the winter, though a considerable number remain along the coasts of some of the more northern countries. The body of the redshank is as big as a snipe's, but its longer neck, wings and legs make it appear larger. Above, the general colour is greyish-drab, freckled with black, except the lower part of the back and a conspicuous band on each wing, which are white, while the flight-quills are black. The bird nests in inland localities as well as by the sea. The males in spring have a beautiful song-flight, rising and falling with quivering wings, and a striking courtship on the ground. They are very pugnacious, fights often continuing for over an hour. The redshank is very wary, and is disliked by shore gunners for giving the alarm to other species. The nest is generally concealed in a tuft of rushes or grass in the swamp whence the bird gets its sustenance, and contains four eggs of a warmly tinted brown with blackish spots or blotches.

The black, dusky or spotted redshank (*T. erythropus*) is a larger and less common bird, and in the greater part of Europe it only occurs on its passage to or from its breeding-grounds, which are south of the Arctic circle. The spot chosen for the nest is

nearly always in forests and at some distance from water. In breeding-dress the head, neck, shoulders and lower parts are black, the back and rump white, while the legs become crimson. At other times of the year the plumage is similar to that of the common redshank and the legs are of the same light orange-red.

REDSTART or **FIRETAIL** (*Phoenicurus phoenicurus*), a small bird which is a summer visitor to Europe, where it haunts gardens, orchards, and old buildings. Its habit of flirting its red tail, and the white forehead, black throat, and bay breast of the cock are distinguishing features; the hen is more plainly coloured; but the characteristic colouring and action of the tail pertain to her equally as to her mate. The nest is almost always placed in a hole of a tree or building, and contains from five to seven eggs of a delicate greenish blue, occasionally sprinkled with faint red spots. The young on assuming their feathers present a great resemblance to those of the redbreast (*q.v.*) at the same age; but the red tail, though of duller hue than in the adult, forms even at this early age an easy means of distinguishing them. The redstart breeds regularly in all the counties of England and Wales. It also reaches the extreme north of Scotland; but in Ireland it is very rare. It appears throughout the whole of Europe in summer, and is known to winter in the interior of Africa. Several very nearly allied forms occur in Asia; and one, *P. aurorea*, is found in Japan.

The black redstart (*P. ochrurus*) is darker than the preceding, with a more southerly range. Like the last, however, it winters in Africa. It often haunts the vicinity of houses. The males of the black redstart seem to be more than one year in acquiring their full plumage.

Allied to the redstarts are the bluethroats (*q.v.*). These groups belong to the subfamily *Turdinae* of the thrushes. The American redstart (*Setophaga ruticilla*) belongs to the purely New World family *Mniotiltidae*, and ranges from Canada (in summer) to Bolivia, but is rare on the Pacific coast. The salmon of the breast, wings, and tail of the male are replaced by yellow in the female. The painted redstart (*S. picta*) has a deep red breast and belly. It inhabits the Mexican plateau, extending north to Arizona and New Mexico.

REDUCTION, in chemistry, metallurgy, etc., means the taking up of hydrogen or the giving up of oxygen, and hence also the taking up of elements which can replace hydrogen or the giving up of elements which can replace oxygen. It is, in fact, the converse of oxidation (*q.v.*).

RED WING, a city of Minnesota, U.S.A., on the Mississippi river, just below the mouth of the Cannon and near the head of Lake Pepin, 40 m. S.E. of Saint Paul; the county seat of Goodhue county. It is on Federal highway 61, and is served by the Chicago Great Western and the Chicago, Milwaukee, St. Paul and Pacific railways and by motor bus lines. Pop. (1920) 8,637, estimated at over 10,000 in 1928. In 1695 Le Sueur established a post on Prairie island, 8 m. above Red Wing, and in 1727 René Boucher built a fort (abandoned in 1753) on the shore of Lake Pepin. A village of the Dakotas had long occupied the site of the city when in 1837 two Swiss missionaries visited it and established a mission which they maintained until 1846. In 1848 a second mission was established by the American Board. The city was platted in 1853 and chartered in 1857. Its name is a translation of the name of the Dakota chief who had settled his people here, and who is buried on the top of Barn Bluff.

REDWING, a species of thrush (*q.v.*), *Turdus musicus*, a winter visitor to the British Islands, arriving in autumn about the same time as the fieldfare (*q.v.*). It is very similar to the song-thrush, but with a white streak over the eye, and the sides of its body, inner wing-coverts and axillaries reddish-orange. The redwing breeds in colonies in woods in subarctic Europe and Asia to Lake Baikal. In winter it migrates as far south as North Africa and the Himalayas. Its song has often been praised, but is disappointing in comparison with that of the song-thrush or blackbird. In its winter quarters it often gives a peculiar inward song in early spring, while still in flocks. Its nest and eggs resemble those of the blackbird.

REDWOOD, SIR BOVERTON (1846–1919), British chemist, was born on April 26, 1846, and educated at University College school, London. He was trained as a pharmacist, but early specialised in the study of petroleum, becoming in 1869 secretary of the Petroleum Association and subsequently studying oil conditions at first hand in many parts of the world (1883–86). He served on several important Government commissions both before and during the World War. Founder of the Society of Petroleum Technologists, he became its first president 1913–14 and he was also a member of many other societies in pure and applied science. He was knighted in 1905, was made a baronet in 1911 and died in London on June 4, 1919. Redwood wrote some standard books on his subject, including *Petroleum*, 3 vol. (1913); and many articles and pamphlets.

REDWOOD (*Sequoia sempervirens*), a gigantic north-west American, coniferous tree, reaching a height of 340 feet. The allied *S. gigantea* of California (discovered in 1850 in the Sierra Nevada) is thicker but not so tall (320 ft.). Both are valuable timber trees. (*See* SEQUOIA.)

REDWOOD CITY, a town of California, U.S.A., on Redwood creek, 30 m. S. by E. of San Francisco; the county seat of San Mateo county. It is on Federal highway 101, and is served by the Southern Pacific railway. The population was 4,020 in 1920 and was estimated locally at 11,500 in 1928. The town was settled about 1856 and incorporated in 1867.

REDWOOD HIGHWAY, an American highway 479 m. long commencing at San Francisco, Calif., and terminating at Grants Pass, Ore. About one-third is paved and most of the balance gravel. From Crescent City, Calif., to Eureka, the highway passes close to the Pacific coast, now high up on the cliffs and again down by the sea. It passes through 100 m. of ancient redwood forests 20 m. wide, whose trees are 200 and 300 ft. high, very straight, and as much as 30 ft. in diameter. South of Eureka the principal points touched are Fortuna, the Humbolt State Redwood park, Ukia and Santa Rosa.

RED WOODS, INSOLUBLE. Under this designation, sanderswood (*Pterocarpus santalinus*, Tropical Asia), barwood (*Baphia nitida*, West Coast of Africa) and camwood come into commerce. These closely resemble one another in tinctorial property, and contain colouring matters which are sparingly soluble in water. They may be applied to wool without the aid of a mordant, though in general the material is first dyed and a mordant, usually bichromate of potash, added to the dye-bath. The shade given with sanderswood and barwood is dull red brown, with camwood a more violet tint. Both sanderswood and barwood still find employment for "topping" indigoes, *i.e.*, the indigo-dyed woollen material is treated in a boiling bath with one or other of these dyewoods. Little is known of the chemical structure of the colouring matters of these dyewoods.

REED, JOSEPH (1741–1785), American politician, was born in Trenton, N.J., on Aug. 27, 1741. He graduated at Princeton in 1757, studied law in 1763–65 at the Middle Temple, London, and then practised in Trenton until his removal to Philadelphia in 1770. He was aide-de-camp and military secretary to Gen. Washington in 1775–76, and was adjutant general in 1776–77. In 1777–78 he was a delegate to the Continental Congress. From 1778 to 1781 he was president of the State executive council. During his administration the proprietary rights of the Penn family were abrogated (1779), and provision was made for the gradual abolition of slavery (1780). Reed was elected to Congress in 1784, but died in Philadelphia on March 5, 1785.

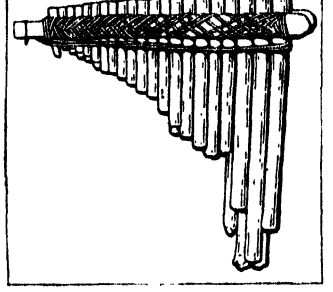
The Life and Correspondence of Joseph Reed (Philadelphia, 1874), by his grandson, William B. Reed, is based upon the family papers. It pictures Reed as an heroic patriot and statesman; George Bancroft, on the other hand, in the ninth volume (p. 229) of his *History* (1866) and in *Joseph Reed: an Historical Essay* (1867), pictures him as a trimmer of the most pronounced type. Bancroft withdrew his most specific charge in the 1876 edition of his *History*, in which, however, his tone towards Reed was unchanged.

His grandson, WILLIAM BRADFORD REED (1806–76), graduated at the Pennsylvania university in 1822. He was professor of American history in the University of Pennsylvania in 1850–56. United States minister to China in 1857–58, and in 1858 negotiated a treaty with China, proclaimed in 1860.

REED, THOMAS BRACKETT (1839–1902), American statesman, was born in Portland, Me., on Oct. 18, 1839. He graduated at Bowdoin college in 1860, and in 1865 was admitted to the bar. He was a member of the Maine House of Representatives in 1868–69 and of the State Senate in 1870, was attorney-general of the State in 1870–72, and was city solicitor of Portland in 1874–77. He was a Republican member of the National House of Representatives from 1877 until 1899, of which he was speaker in 1889–91 and in 1895–99. He was a "strong" speaker in his control of the proceedings, and he developed an organized committee system, making the majority of the committee on rules consist of the speaker and chairman of the committees on ways and means and on appropriations. The "Reed rules," drawn up by him, William McKinley and J. G. Cannon, were adopted on Feb. 14, 1890; they provided that every member must vote, unless pecuniarily interested in a measure, that members present and not voting may be counted for a quorum, and that no dilatory motion be entertained by the speaker. His parliamentary methods were bitterly attacked by his political enemies, who called him "Tsar Reed." His rules and methods of control of legislation were adopted by his successors in the speakership, and the power of the rules committee was greatly increased. After the war with Spain Reed broke with the administration on the issue of imperialism. He resigned his seat in 1899 and practised law in New York city. He died in Washington on Dec. 7, 1902. Reed was a remarkable personality, of whom many good stories were told, and opinions varied as to his conduct in the chair; but he was essentially a man of rugged honesty and power.

Reed's Rules were published as a parliamentary manual. He edited with others a *Library of Modern Eloquence* (1901). *See* the chapter on Reed in H. B. Fuller's *Speakers of the House* (Boston, 1909).

REED, WALTER (1851–1902), American bacteriologist, was born in Gloucester county, Va., on Sept. 13, 1851, and was educated at the University of Virginia and Bellevue Medical school (M.D., 1870). In 1874 he entered the medical corps of the U.S. army as assistant surgeon, with rank of lieutenant. In 1893 he was promoted to surgeon, with the rank of major, and made professor of bacteriology in the newly-organized Army Medical school. In 1898, when the Spanish American War opened, he was appointed chairman of a committee to investigate the causation and mode of propagation of typhoid fever, an epidemic of which had broken out among the soldiers. His *Report on the Origin and Spread of Typhoid Fever in U.S. Military Camps* (1904) revealed a number of points concerning the disease not before known, and emphasized others which had been little appreciated. In 1897 he and an associate proved the theory of Sanerelli—that the bacillus icteroides was the specific cause of yellow fever—erroneous. In 1899, when the disease was especially severe in Cuba, he was made chairman of a committee to investigate its cause and method of transmission. His observation of many cases led him to discount the then prevalent idea that the disease was transmitted by fomites in bedding, clothing, etc., of patients suffering from yellow fever, and to revive the discarded notion of Dr. Carlos Finley that the yellow fever parasite was carried only by mosquitoes. Since the disease was not taken by animals there was no method of proof except by experiment upon human beings. By a thorough set of experiments, in which some of Reed's coworkers sacrificed their lives for the cause, he proved to a sceptical world that the yellow fever parasite was carried only by the mosquito *Stegomyia fasciata* and that its bite caused the disease only under certain conditions. Possessed of this knowledge, American sanitary engineers eradicated the yellow fever from Cuba, and it has since been largely eliminated from civilized portions of the world. Reed died at Washington, D.C., on Nov. 23, 1902.



See H. A. Kelly, *Walter Reed and Yellow Fever* (1906), which contains a bibliography of Reed's publications; also P. De Kruif, *Microbe Hunters*, pp. 311–333 (1926).

REED, a term applied to several distinct species of large, water-loving grasses. The common or water-reed, *Phragmites communis* (also known as *Arundo phragmites*), occurs along the margins of lakes, fens, marshes and placid streams, not only throughout Great Britain and the United States, but widely distributed in Arctic and also in temperate regions. Another very important species is *Ammophila arenaria* (also known as *Psamma arenaria*), the sea-reed or marram-grass, a native of the sandy shores of Europe and north Africa. Both species have been of notable geological importance, the former binding the soil and so impeding denudation, and actually converting swamp into dry land, largely by the aid of its tall (5 to 10 ft.) close set stems. The latter species, of which the branching rootstocks may be traced 30 or even 40 ft., is of still greater importance in holding sand-dunes against the sea, and for this purpose has not only been long protected by law, but has been extensively planted on the coasts of Norfolk, Holland, Gascony, etc. Other reeds are *Calamagrostis* (various species), *Gynerium argenteum* (pampas grass), etc., also *Arundo Donax*, the largest European grass (6 to 12 ft. high), which is abundant in Europe. Reeds have been used from the earliest times in thatching and in other branches of construction, and also for arrows, the pipes of musical instruments, etc. Reed pens are still used in the East. Plants belonging to other orders occasionally share the name, especially the bur-reed (*Sparganium*) and the reed-mace (*Typha*), both belonging to the family Typhaceae. The bulrushes (*Scirpus*), belonging to the family Cyperaceae, are also to be distinguished.

REEDBUCK, a foxy-red South African antelope (*Cervicapra arundineum*) of medium size, with a bushy tail, a bare gland-patch behind the ear, and in the male short horns which bend forwards in a regular curve. There are several other species of the genus *Cervicapra* to which the name of reedbuck is also applied, one of these ranging as far north as Abyssinia, and another inhabiting west Africa.

REED INSTRUMENTS, a class of wind instruments in the tubes of which sound-waves are generated by the vibrations of a reed mouthpiece. Reed instruments fall into two great classes: (1) those blown directly by the breath of the performer, who is thus able to control more or less the character of the expression; (2) those in which the wind supply is obtained by mechanical devices, such as the bag of bagpipe instruments or the bellows of such keyboard instruments as the organ and harmonium.

Directly-blown reed instruments comprise the section of modern wind instruments known as the "wood wind," with the exception of flute and piccolo; and they are classified according to the kind of reed vibrator of which the mouthpiece is composed. There are three kinds of reed mouthpieces: (1) the single or beating reed; (2) the double reed; (3) the free reed, all of which perform the function of sound-producer. (For illustration *see* FREE REED VIBRATOR.) The reed used consists of a thin tongue or strip of reed, cane or some elastic material, thinned gradually to a delicate edge. It is adapted to the tube in such a manner that when it is at rest the opening at the mouthpiece end of the tube consists only of a very slight aperture or chink, which is periodically opened and closed by the pulsations of the reed when acted upon by the compressed breath of the player. This principle is common to all reed mouthpieces, and the difference in timbre is in a measure due to the manner in which the pulsations are brought about and the degree of elasticity permitted.

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

THE ANCIENT SYRINX OR PIPES OF PAN, CONSISTING OF TUBES OF VARYING LENGTHS, BOUND TOGETHER

The *single* or *beating reed* consists of a single blade bevelled at the edge and placed over a table or frame communicating with the main bore of the instrument, against which it beats, causing a series of pulsations. The single reed is common to all the members of the clarinet family, consisting, besides the clarinet, of the basset-horn or tenor, and of the bass and pedal clarinets; of the batyphone, an early bass clarinet, and of the saxophone. The ancient Greek aulos (*q.v.*) was also undoubtedly used with a beating

reed during some period of its history.

The *double reed* consists of two blades of reed or other suitable material tightly bound together by many turns of waxed silk, so that above the constriction the tube formed by the two blades has an oval section, while below, where it communicates with the main bore of the instrument, it is strictly cylindrical. The chink in this case is thus formed by two thin walls of reed of equal elasticity (*see* OBOE, BASSOON). The double reed is common to the members of the oboe family, consisting, besides the oboe, of the cor anglais or tenor, of the fagotto or bassoon, and of the contra fagotto or double bassoon; and it is also used in the sarrusophone family, instruments of brass but classed with the wood wind on account of the mouthpiece and fingering.

The *free reed* is not represented among members of the modern wood wind, and, as adapted to a directly-blown instrument, only finds application in the Chinese cheng, the prototype of the harmonium, and in the mouth-organ or harmonica.

The reed in wind instruments produces a peculiar tone quality to which it has given its name; it varies in the three different kinds of mouthpieces without losing its fundamental reedy timbre.

For reed instruments of the second class, viz., those indirectly blown by mechanical means, *see* under the names of the individual instruments—BAGPIPE, CONCERTINA, HARMONIUM, ORGAN, etc.

REEVE, an English official who in early times was entrusted with the administration of a division of the country. He was the chief magistrate of a town or district, and is the ancestor of the sheriff, the shire-reeve. In addition to the sheriff there were several kinds of reeves.

REEVE, in ornithology, the female of the ruff (*q.v.*).

REEVES, JOHN SIMS (1818–1900), English vocalist, was born at Woolwich on Sept. 26, 1818, and received his musical education from his father, a musician in the Royal Artillery. He studied with Hobbs and T. Cooke, and, his voice having become a tenor, he appeared under Macready's management at Drury Lane (1841–43) in subordinate tenor parts in Purcell's *King Arthur, Der Freischütz,* and *Acis and Galatea.* Four years were spent in study on the Continent, under Bordogni in Paris and Mazzucato in Milan, and his *début* in Italian opera was made at Scala as Edgardo in *Lucia.* He reappeared in London in May 1847, and his career on the English operatic stage began at Drury Lane in Dec. 1847 in *Lucia,* under the conductorship of Hector Berlioz. At the Norwich Festival (1848) he made a great sensation in "The enemy said," from *Israel in Egypt.* He was recognized as the leading English tenor; and in Costa's *Eli* and *Naaman* the tenor parts were written for him. His first Handel Festival was that of 1857, and the effect of his wonderful declamation in the Crystal Palace was a main attraction of this and of many subsequent festivals. He died at Worthing on Oct. 25, 1900.

REEVES, WILLIAM PEMBER (1857–), New Zealand administrator, was born at Canterbury, New Zealand, on Feb. 10, 1857, and educated at Christchurch, N.Z. He read for the law and was called to the New Zealand bar, but eventually took up journalism, becoming editor of the *Canterbury Times* and the *Lyttelton Times.* In 1887 he entered parliament, and held office from 1891 to 1896 as minister of education. He has published several volumes on the history of New Zealand, and one volume of verse, and contributed to the 10th and to the present editions of the *Encyclopædia Britannica.*

RE-EXPORTS: *see* EXPORTS.

REFECTORY, the dining-hall of a monastery, convent, etc. There frequently was a sort of ambo, approached by steps, from which to read the *legenda sanctorum,* etc., during meals. The refectory was generally situated by the side of the south cloister, so as to be removed from the church but contiguous to the kitchen. The word is also sometimes applied to any large hall used for community meals, as in a college, school, etc.

REFEREE, a person to whom anything is referred; an arbitrator. The court of referees in England was a court to which the House of Commons committed the decision of all questions as to the right of petitioners to be heard in opposition to private bills. The court now consists of the chairman of ways and means, the deputy chairman and not less than seven other members of the House appointed by the Speaker, and its duty, as defined by a standing order, is to decide upon all petitions against private bills, or against provisional orders or provisional certificates, as to the rights of the petitioners to be heard upon such petitions. In the High Court of Justice, under the Judicature Act 1873, cases may be submitted to three official referees, for trial, enquiry and report, or assessment of damages. Enquiry and report may be directed in any case, trial only by consent of the parties, or in any matter requiring any prolonged examination of documents or accounts, or any investigation which cannot be tried in the ordinary way.

United States.—The term referee is commonly applied to persons to whom a court sends a cause or some question therein for determination or for the purpose of taking evidence and reporting upon the same. In this connection it is synonymous with such terms as auditor, commissioner, arbitrator, assessor, etc. In some states the term is applied to a master, who is appointed in equity suits pursuant to statute as distinguished from masters appointed pursuant to the old equity practice. *See* EQUITY.

REFERENDUM and **INITIATIVE,** two methods by which the wishes of the general body of electors in a constitutional state may be expressed with regard to proposed legislation. They are developed to the highest extent in Switzerland, and are best exemplified in the Swiss federal and cantonal constitutions. By these two methods the sovereign people in Switzerland (whether in the confederation or in one of its cantons) approve or reject the bills and resolutions agreed upon by the legislative authority (Referendum), or compel that authority to introduce bills on certain specified subjects (Initiative)—in other words, exercise the rights of the people as regards their elected representatives at times other than general elections. The *Referendum* means "that which is referred" to the sovereign people, and prevailed (up to 1848) in the federal diet, the members of which were bound by instructions, all matters outside which being taken "ad referendum." The *Initiative,* on the other hand, is the means by which the sovereign people can compel its elected representatives to take into consideration either some specified object or a draft bill relating thereto, the final result of the deliberations of the legislature being subject by a referendum vote to the approval or rejection of the people. These two institutions therefore enable the sovereign people to control the decisions of the legislature, without having recourse to a dissolution, or waiting for the expiration of its natural term of office.

Two forms of the Referendum should be carefully distinguished: the *facultative* or optional (brought into play only on the demand of a fixed number of citizens), and the *obligatory* or compulsory (which obtains in all cases that lie within its sphere as defined in the constitution). The Initiative exists only in the facultative form, being exercised when a certain number of citizens demand it. Both came into common use during the Liberal reaction in Switzerland after the Paris revolution of July 1830. In 1831 St. Gall first adopted the "facultative referendum" (then and for some time after called the "Veto"), and its example was followed by several cantons before 1848. The "obligatory referendum" appears first in 1852 and 1854 respectively in the Valais and the Grisons, when the older system was reformed, but in its modern form it was first adopted in 1863 by the canton of rural Basel. The Initiative was first adopted in 1845 by Vaud. In the case both of the facultative referendum and of the Initiative each canton fixes the number of citizens who have a right to exercise this power. The constitution of the Swiss confederation lags behind the constitutions of the cantons. Both institutions have since their adoption been freely and constantly used in connection with federal and cantonal proposals.

British Empire.—In *Australia* the referendum, which had been used only once before 1910, was used on several occasions during the ensuing 15 years. In 1910 itself a referendum authorised the transference of the debts of the various states to the Commonwealth Government. In 1916, and again in 1917, the vital question of extension to service abroad of the compulsory enlistment (which was already in use for home defence) was referred to the Commonwealth electorate and on each occasion rejected—in 1916 by 1,146,000 to 1,085,000 and in 1917 by 1,180,000 to 1,015,-

000. In 1911, 1913 and 1919, amendments to the Commonwealth Constitution of a Socialist tendency were all rejected. Similarly in the separate states of the Commonwealth, *e.g.*, Victoria, 1920, Queensland, 1923, and New South Wales, 1925, proposals in favour of prohibition were defeated by large majorities.

New Zealand used the machinery of the referendum in 1911, 1914, 1919, 1922, 1925 and 1928 in order to discover the will of her people respecting this same vexed question of prohibition. On each occasion prohibition was rejected, and at the last referendum in Nov. 1928 a large majority voted against prohibition.

Canada.—The referendum in the legislative sense has, when resorted to, been as a rule the result of special laws, and particularly on the question of prohibition. The suppression of the liquor traffic was thus carried out in Alberta, 1915, Manitoba, British Columbia and Saskatchewan in 1916, and Ontario in 1919. In 1920, however, British Columbia by means of a referendum, reversed its decision and adopted a system of government liquor control—an example subsequently followed by Manitoba, Saskatchewan, Alberta and Ontario. Under United States influence the referendum has been widely introduced into local government matters, more particularly as regards the submission of by-laws about money to the people, and in this restricted sense has operated successfully, though upon occasions it has proved difficult to induce any large number of voters to exercise the franchise.

Irish Free State.—The Irish Free State Constitution, 1922, requires a referendum to be taken on any measure passed by the Dail, if a demand is made by either one-fifth of the senate or one-twentieth of the electorate.

European Countries.—The Swedish Constitution, dating from 1809 and subsequently altered on several occasions, contains a provision for referring measures of importance to the opinion of the people. In 1922 a referendum on prohibition was taken in pursuance of this provision and owing to the action of the electorate in the large cities the proposal was defeated. Several Constitutions, framed since the World War, have incorporated the referendum as part of the machinery of government. The German Constitution of 1919 empowers the president to order a referendum when he sees fit, and provides it also as a means of escape from a conflict between *Reichstag* and *Reichsrat*. It was used on June 20, 1926, to decide the question as to whether or not property of the Hohenzollerns or other former ruling houses should be confiscated. Over 15,000,000 votes were cast for confiscation, but as less than half the total votes was polled, the proposal failed. The Constitutions of some of the constituent States of the *Reich* (such as Bavaria and Prussia), adopted since 1919, also contain provisions for the initiative and the referendum. (*See* GERMANY.)

The Estonian Constitution of 1920 uses it as a means of resolving a deadlock between the two houses of legislature. The rejection of a measure passed by the representative assembly involves the dissolution of the assembly and a general election within 75 days. Provisions for a referendum also occur in the Constitutions of Lithuania and Latvia.

The Austrian Constitution provides for a popular initiative demand for legislation when supported by 200,000 voters or by half the voters of three Provinces. This demand must be expressed in the form of a draft bill. Under this Constitution, every general alteration of the Constitution must be submitted to a referendum, and in certain circumstances, any partial alteration of the Constitution or any law may be referred to a popular vote. In the Constitution of the Czechoslovak republic, it is provided that the Government, if unanimous, may refer a bill rejected by the national assembly to a popular vote, but no such referendum was to be placed upon any government proposal to amend the Constitution.

The United States.—The legislative referendum was formally adopted by Arkansas and Colorado in 1910, by Arizona, California and New Mexico in 1911, by Nebraska, Idaho, Ohio and Washington in 1912, by Michigan in 1913, by Mississippi and North Dakota in 1914, by Maryland in 1915, and by Massachusetts in 1918. Its chief adherents still lie west of the Mississippi River, only five eastern states having adopted it, *i.e.*, Maine, Massachusetts, Maryland, Ohio and Michigan,—and 26 states have made no provision for direct legislation.

On the other hand the constitutional referendum, which contemplates only proposed amendments to the state constitutions, is in force in every state with the exception of New Hampshire and Delaware, and this is the form in which the referendum has been usually resorted to in recent years. The constitutional problems most persistently laid before the electors for decision were female suffrage and prohibition. As a result of referenda, the suffrage was given to women in some states, *e.g.*, Washington in 1910 and California in 1911, but refused in others, *e.g.*, Oklahoma in 1910 and South Dakota in 1911. The subject of prohibition was thrashed out over almost the entire United States by means of referenda, until the matter was removed from the cognizance of the state legislatures and electorates by the eighteenth (prohibition) amendment to the federal constitution. Apart from the wider state spheres of action, the referendum has been adopted in local government matters, particularly in the matter of money bylaws which in certain circumstances have to be submitted to the taxpayers for their approval, and also in connection with the adoption or otherwise of the commission and city manager systems of municipal government. In some of the States an analogous institution, the "Recall," enables the electors of a district to determine the office of a popularly elected judicial or administrative officer prior to the close of the term for which he was originally elected.

REFLECTION. When waves of any kind travelling in one medium arrive at another in which their velocity is different, part of their energy is, in general, turned back into the first medium. This is termed reflection. If the surface of separation is smooth, *i.e.*, if the irregularities in it are small compared with the wave length of the incident disturbance, the reflection is *regular;* if the surface is rough each facet reflects the rays incident upon it in accordance with the laws of regular reflection (*see* LIGHT) and the reflection, as a whole is *irregular* or *diffuse*. Consider, for example, the reflection of light at smooth and ruffled water surfaces. From the ruffled surface rays enter the eye after reflection from suitably inclined facets distributed over a wide area on the surface and a diffuse band of light is seen, while from the smooth surface only those rays reflected at the requisite angle from a small area on the surface can reach the eye. In the first case the optical system of the eye focusses the water surface on the retina just as it does all other rough surfaces. In the latter the rays appear to come from a laterally inverted replica of the luminous source situated as far below the surface as the source itself is above, and it is this *image* which is then focussed on the retina. The diffusion of light by matt surfaces in general is an example of the same phenomenon differing only in the number and size of the facets which scatter the light.

Echoes and reverberations are caused by the reflection of sound (*q.v.*) and the "fading" of wireless signals (in part) by variations in the conditions under which the electromagnetic waves are reflected by the Heaviside layer in the upper atmosphere. (*See* WIRELESS TELEGRAPHY, THEORY OF.)

REFLECTORS. The light from most illuminants is distributed in a manner such that under most conditions it cannot be efficiently employed without the use of reflectors, or other media for re-directing the light into useful angles. Reflectors in common usage to-day not only control the direction of the light, but also

serve to shield the eyes from the brilliancy of the bare light source, and diffuse the light to produce a comfortable illumination. While all materials have to some degree the qualities of reflection, only a few can be used efficiently as accessories for primary light sources. Consideration of permanence, transmission, opacity, character of surface and reflection factor are necessary in determining the fitness of materials for use as reflectors.

The materials ordinarily used for reflectors are classed as (1) translucent, in which a part of the incident light is reflected and part transmitted or absorbed, and (2) opaque, in which part of the light is reflected and the rest absorbed; both types are necessary depending upon the character of the light distribution. The three types of light distribution from reflectors used for general interior illumination are classed as (1) direct, (2) semi-indirect and (3) indirect, a classification based upon the percentage of emitted light below or above the horizontal plane through the centre of the light source. Direct reflectors shed more than half of the emitted light below the horizontal; semi-indirect reflectors throw more than half above the horizontal with a small amount below; and indirect reflectors throw all of the light upward to the ceiling which reflects it downward.

The shape of the candle-power distribution curve of a reflector is within the control of the designer because of the diverse types of reflection characteristics available. Where very accurate control of the light is necessary, polished-metal, mirrored-glass, or prismatic-glass surfaces are usually employed. These media have a reflection characteristic similar to a mirror where the angle of reflection is equal to the angle of incidence. Automobile headlight reflectors, searchlight and floodlight projectors, and industrial high mounted luminaires are typical of the equipment requiring this type of reflector. An inconsiderable corrugation of surface of this type produces a slight diffusion of the light and yet permits of a very accurate control of the light distribution. Dull-finished metal surfaces, of which unpolished aluminium is typical, have some of the light-directing characteristics of the polished surface but more diffusion. This type of surface is commonly used for small local lighting reflectors and in some types of floodlights and spotlights. The inherent low cost, ease of manufacture and light weight make spun aluminium popular for many uses.

Rough or mat-finish reflecting surfaces permit of little or no actual control of light, since a beam of light striking a mat-finish surface will be reflected in all directions. Block magnesium carbonate is typical of several surfaces falling in the classification, although it lacks the necessary permanence, soils easily, and is difficult to clean. Porcelain enamelled metal combines the diffusing characteristics of mat-finish surfaces with some of the light control characteristics of gloss surfaces. Porcelain-enamelled reflectors are popular for industrial lighting purposes because of the ease of cleaning them when they get dirty. The cost is low because the metal shell can be formed by spinning, or in the press, and the porcelain enamel finish put on afterwards. Opal glass has the same general reflection characteristics as porcelain enamel and also transmits some light—a feature desirable for some locations. REFORMATION. This word, like "Catholic," is in itself a question-begging term; but both are adopted, if only under protest, in the general speech of the present day. By "Reformation," then, we mean that religious revolution of the 16th century which has divided western Christendom into two camps, the Catholic and the Protestant. This was in itself a very complex movement, due to a multiplicity of causes which may be grouped under four main headings; *moral, doctrinal, economic* and *political.*

Moral Causes.—These were the most important of all, for they lay at the very root. From St. Bernard at the beginning of the 12th century to Bishop Fox, who founded Corpus Christi college at Oxford in 1516, there is no generation from which we cannot choose orthodox and distinguished churchmen who urged the crying need for Church reform in language which might seem harsh from the pen of a modern Protestant. From Innocent III. in 1215 to Leo X. in 1512, nine great world-councils were held, with Church reform in the forefront of their programme; yet each in turn confessed the failure of its predecessors, and the Council of Trent (1545) testified to the impotence of them all.

The attempt to saddle the Black Death (1348–50) with this state of things is grossly unhistorical. Two of the greatest cardinals of the 13th century, St. Bonaventura (d. 1274) and Hugues de St. Cher (d. 1260) were among the most outspoken of all our witnesses against the clerical morals of their day. Even plainer is the testimony of another very distinguished bishop, Guillaume Durand, who was consulted for the Council of Vienne (1311). In his long memorial, he drew a terrible picture of the reigning and growing abuses, and concluded that the thing most needful was "a reformation in head and in members," that is, from the pope and his court downwards; and this became a watchword not only at succeeding councils, not only among outside critics, but sometimes of popes. It is acknowledged on all hands that the abuses emphasized at the council of 1215 were in many respects even more rampant in 1512, and that the discipline so often demanded was never realized until after the Council of Trent had completed its long work (1564).

The celibacy of the clergy had presented great and continual difficulties. (*See* CELIBACY.) Even so energetic a reformer as St. Anselm was practically compelled to abandon his design of separating the English clergy from their partners. A visitation of the diocese of Hereford in 1397 shows 52 concubinary clergy known to the bishop out of 281 parishes. Another of Lausanne diocese in 1416–17 shows, among 273 communities, more than 80 clergy known as concubinary. The Oxford chancellor Gascoigne (1450), a strong anti-Lollard, tells us that the bishop of St. Asaph of his day was earning 400 marks (the equivalent of something like £5,000 a year in modern money) from the licences for concubinage that he sold to his priests; and, though these figures are doubtless greatly exaggerated, yet Sir Thomas More does not deny that there was something of the same system in Ireland; and similar evidence comes to us from other parts of Europe.

It is rare to find any mediaeval author who, if he generalizes about monks, friars and nuns at all, fails to complain of the immoral example which they too frequently set.[1] St. Bernardino of Siena (d. 1444) tells us that "very many" men of his day had no belief in Heaven, and looked upon the Christian scriptures as merely interesting figments, because of the evil lives of cloisterers and other clergy. Pope Gregory X. had said the same at the council of Lyons (1274), and by about 1500 it had become a commonplace that the lives of the clergy were mainly responsible for the increase of heresy. And some of the most distinguished mediaeval witnesses, such as Cardinal Hugues de St. Cher (d. 1260) and St. Catharine of Siena (d. 1380) point out that clerical vices were naturally reflected and even exaggerated in the laity. Again, long before Luther's appearance, orthodox Catholics were emphasizing the abusive side of many Church ceremonies and practices; the sale of indulgences (*q.v.*), the multiplication of holy-days and the vice and riot which often marked these festivals; the abuse of the mass and of the consecrated oils for witchcraft; and the extent to which clerical immunities encouraged crimes. The laity of the later middle ages, with all their faults, were improving far more rapidly than the clergy; and this gave a proportionately increasing impetus to criticism.

Doctrine.—Here the clergy had once been supreme, and would probably have had little difficulty in maintaining their authority if they had kept unquestionable moral superiority. Few people are really interested in pushing theological enquiries very far, and, so long as men's conduct corresponds to their doctrine, the vast majority of mankind are willing to accept this at least as a working theory, and are under no temptation to question the speculative basis of practices which they approve. So long as there was no deep gulf between what the clergy actually were and what the people had a right to expect of them, free-thought was mainly limited to a few philosophers here and there, to a few weavers at their loom or cobblers at their bench, and to that dead weight of indifference, of resistance against idealism of any kind, which

[1] More than 100 orthodox witnesses are cited on pp. 379–419 of G. G. Coulton's *Five Centuries of Religion*, Vol. II.

has prevailed in every generation among the masses who need to concentrate so much of their thoughts and their labour upon the elementary problems of daily bread. We have abundant proof that the majority of the mediaeval population were not actively religious; but for a long time the enthusiastic churchman had generally nothing worse to struggle with than inertia and complacent ignorance. About the year A.D. 1000, there came a revival comparable almost to that which we call the Renaissance. With this revival we also find signs of free-thought and religious friction; an ice-bound world was now thawing; therefore it moved less regularly and under less strict control than might have been desired. Many features of the then existing dogmatic scheme had been created less by profound philosophy than by popular feeling or by comparatively unreflecting impulses. All men, for instance, had gradually grown to assume that we must take that text "many are called, but few are chosen," in its most baldly literal sense. Even in the 13th century, and in a philosopher so remarkable for balance and moderation as St. Thomas Aquinas, we find that the "few" who shall be saved are directly contrasted with the "very many" who shall go to hell. His contemporary, the Franciscan Berthold of Regensburg, whom Roger Bacon singles out as the greatest preacher of the day, actually commits himself in one passage to a rough numerical calculation; only about one in 100,000 shall be saved; and few mediaeval theologians put it more favourably than one in 1,000.

Moreover, they exerted all their imagination and their rhetoric to impress upon their hearers the terrible significance of this separation between the sheep and the goats. All was to depend upon the last moment of life; and, even there, it must depend mainly upon the faith in which the sinner died. Berthold asks his hearers to imagine themselves writhing white-hot within a white-hot universe until the day of judgment, when the pains will be greatly increased. Let them imagine this continuing for as many years as all the hairs that have grown upon all the beasts in this world since the creation; and, even then, the sinner will be only at the beginning of his torments. Yet Berthold was one of the kindliest of men; if he defended the current dogma with this ferociously implacable logic, it was because he had inherited it as part of the deposit of faith, and because he now found himself faced by an opposition which no student of the Reformation can afford to ignore.

Heresy.—The first half of the 12th century had witnessed the rise of several powerful heretical sects, which even the eloquence and influence of men like St. Bernard could not extinguish, though the leaders could be taken and slain. All these sects were more or less antisacerdotal; and more than one held among its chief tenets that the personal unworthiness of the priest impairs or destroys the value of the sacrament which he administers, a doctrine to which some colour had been lent by the very methods taken to combat clerical concubinage by the great pope Gregory VII. (d. 1085).

Towards the end of the century, these popular and comparatively unlearned revolts were succeeded by others of very different intellectual weight. The Waldensians [1175] took their stand upon the Bible; this they read in the vernacular, and committed to memory with a diligence which, as even their persecutors complained, ought to have shamed the orthodox out of their ignorance.

About the same time, the complete works of Aristotle began to filter into the University of Paris through translations from the Arabic, and, a little later, through more accurate versions made by orthodox scholars. The Bible led the Waldensians to deny any essential distinction between clergy and laity; but they long persisted in regarding themselves as orthodox Catholics. The new Aristotle, and especially his Arabic translators and commentators, led a certain number of Paris teachers to adopt the teaching of Averroes (*q.v.*), and thus to deny such fundamental doctrines as the personality of God, the creation, and the immortality of the soul.

But stern measures of repression, first by bishops and clergy and then by the Inquisition (*q.v.*), prevented the general diffusion of these doctrines. In southern France, indeed, about 1200, it was complained that the heretics outnumbered the Catholics; but Innocent III. exterminated them in a merciless crusade; and the new orders of friars, instituted soon afterwards, did almost as much as the sword and the Inquisition to crush movements which were necessarily sporadic and disorganized, since there was no chance of bringing that side of university scholarship into quiet and steady co-operation with the less articulate impulses of the multitudes. Moreover, from the very first, there was naturally a good deal of base leaven in these revolts; and even the Waldensians, whose original tenets resembled modern Quakerism in a good many respects, were gradually compelled, under persecution, to make common cause with other rebels whom they had begun by opposing.

Orthodoxy.—Society as a mass was not ripe for revolution; the nonconformists had too little of a positive programme to substitute for that of the conformists. For the orthodox had gradually set themselves to systematize the theology which they had inherited. Peter Lombard, bishop of Paris (d. 1164) compiled his *Sentences, i.e.*, texts from the Bible and from the fathers, arranged with comments so as to present a fairly consistent foundation upon which most of later mediaeval theology was built. St. Thomas Aquinas (d. 1274) built up a powerful constructive plea for Christianity in his *Summa contra Gentiles* and a wonderfully complete synthesis of Christian tradition with Aristotelian philosophy in his *Summa totius Theologiae*.

From the mid 13th century onwards, there was a tendency in official circles to look upon the intellectual and social equilibrium as complete; philosophers were less concerned to advance than to hold the positions already gained and to strengthen the outworks from generation to generation. Roger Bacon, the slightly older contemporary of Aquinas, might indeed criticize this imposing philosophical structure in terms which almost anticipate Huxley; it rested (he said) upon a Bible misunderstood, and an Aristotle misunderstood, and upon an almost total neglect of the physical and mathematical sciences. But Bacon exaggerates so far as Aristotle is concerned; and he, like those few who thought with him, had no chance in face of the Inquisition; therefore, though a great deal of Averroism survived at the universities, and we have evidence throughout the later middle ages for groups of "intellectuals" who treated Christianity as an outworn superstition, it was improbable that these men would ever have led a revolt. The academic tendency was rather to evade serious issues under shelter of the theory of "double truth"; things (they said) might be theologically true even while they were philosophically false. Far more important was the gradual change of thought among the masses. These, as zealous teachers complained, had always looked too grossly for tangible and immediate results. Saints' images which refused to work expected miracles might be scorned or maltreated; the failure of St. Louis' crusade led common folk to say "nowadays, Mohammed is stronger than Christ." The Black Death inflicted a terrible shock, from which all vital things recovered rapidly, but which shook all mere conventions to their base; to that extent, it must certainly be counted among the hastening factors of the Reformation.

The popes, by their voluntary desertion of Rome for Avignon, did much to impair their prestige, especially in England, where they seemed necessarily partisans of France in the Hundred Years' War. This was expressed in popular rhymes: "The pope is a Frenchman now, but Jesus is English; let us see who will do most, Jesus or the pope!" Then came the Great Schism, with 39 years of struggle between rival popes upon whose claims, though historians are mostly in agreement, the Roman church has never pronounced so clearly and unequivocally as to render it a question settled for all time. Among contemporaries, St. Catharine of Siena was certain that Urban was true pope, and Clement a pretender. But the Spaniard, St. Vincent Ferrer, proves with every reinforcement of scholastic logic, not only that Clement is true pope, but that no man who, having heard the pleas in his favour, decides for Urban, can hope for heaven. The effect of this upon the masses can scarcely be exaggerated; it was the schism, perhaps, which lent its greatest force to the heresy of Wycliffe. For, at the same time, popular devotions and a popular theology were growing up under the wing of the Church,

yet in considerable independence of the priesthood.

Piers Plowman is only one of many books which show how pious and thoughtful folk, outside the hierarchy, were exercised by such problems as predestination, or the damnation of virtuous non-Christians, or the papal doctrine of indulgences (*q.v.*). The multiplication of books of popular piety in the last generations before the Reformation is enormous. For good or for evil, the people were beginning to outgrow clerical tutelage. Even in the foundation of schools and hospitals, the laity were beginning not only to pay their money, as they had done for long past, but to demand control of their own foundations. There was new life everywhere about 1500; but the gains were far more secular than sacerdotal.

Economic Causes.—During the later centuries of the middle ages, clerical possessions were enormous; churchmen owned a proportion which has been variously estimated at one-fifth or one-third of the whole landed property; yet they claimed to be free of taxation by the state. This naturally led to extreme friction; the preamble of Boniface VIII.'s celebrated bull *Clericis Laicos* (1296), in which he strongly asserted this claim for immunity, runs: "That the laity are bitterly hostile to the clergy is a matter of ancient tradition which is also plainly confirmed by the experience of modern times."

Equal friction arose from the farther claim, which had gradually grown up and was finally fixed by John XXII. (1316–34), that all Church benefices belong to the pope, who may appoint whom he will. This naturally led to a systematic trade in benefices at the Roman court: "Nothing is to be had at Rome without money," wrote Aeneas Silvius, the future pope Pius II. (1458–64). The popes took from each bishop half of his year's income (annates), and proportionately from abbots of great monasteries. Justice was sold in all the Church courts even more frequently than by secular judges; from at least the 12th century onwards, it was notorious that the archdeacons derived a large proportion of their income from bribes. These economic causes for reformation are most pithily summed up in the *Hundred Grievances of the German Nation,* laid before Adrian VI. (1522–23) by the German princes.

The Inquisition.—Moreover, the Inquisition itself, by its very constitution, had become a terrible economic burden. It had always paid its way by wholesale confiscations; even "reconciled" heretics must lose their goods. Therefore, when heresy had been nearly stamped out among rich and conspicuous folk, and the few that remained were such as had procured some sort of illegal protection, then (as we are frankly told by the Inquisitor Eymeric, writing about 1350) princes ceased to take an interest in the Inquisition, and it languished for want of funds.

In the later middle ages, the Inquisition directed much of its energies to the suppression of witchcraft; for an enormous number of heathen customs still survived, especially among the peasantry, who formed the overwhelming majority of the population. Many peasants, said Berthold of Regensburg (1250), and especially many peasant women, cannot take any step in life without having recourse to witchcraft. Therefore, easy though it was to raise an outcry against some unpopular individual, any general enforcement of severe measures against witchcraft must have been extremely unpopular. The enormous multiplication of witch-hunts during the 15th century—for on this side Joan of Arc's fate is quite typical—was both symptom and cause of a deep gulf between the ignorant multitude and the theology of leaders like Aquinas. "Every Inquisitor whom [the Church] commissioned to suppress witchcraft was an active missionary who scattered the seeds of the belief ever more widely" (Lea). A bull of Innocent VIII. in 1484 had the practical effect that thenceforward to question the reality of witchcraft was to question the utterance of the vicar of Christ, "Thus the Inquisition in its decrepitude had a temporary resumption of activity" (Lea). Here again, however, we are to some extent anticipating; for the Inquisition was not only an economic but also a political force.

But, before quitting the economic factors, we must remember that they brought as much weakness as strength into the Reformation movement. It is evident that an economically irreproachable Church would have been as impregnable as the earliest Christian society had been; but it is equally true that the purity of reform was very early tainted by greed; so that, when force was used on both sides, there was little or no moral difference between a defensive commercialized hierarchy and an aggressive squirearchy eager for plunder.

Political Causes.—The political factor, though by itself it might never have led to actual revolt, came in at the last stage with decisive effect. It was the struggle with Protestantism which evolved the half-way principle of *cuius regio, eius religio;* "the ruler's choice determines the established religion of his territory"; and this in turn has led to our modern toleration of all creeds. But the mediaeval ideal had been one empire with one religion; and the actual conditions cannot be better described than in the words of the jurist-historian F. W. Maitland (*Canon Law in the Ch. of England,* p. 100), "We could frame no acceptable definition of a State which would not comprehend the [mediaeval] Church. What has it not that a State should have? It has laws, law-givers, law-courts, lawyers. It uses physical force to compel men to obey the laws. It keeps prisons. In the 13th century, though with squeamish phrases, it pronounced sentence of death. It is no voluntary society; if people are not born into it they are baptized into it when they cannot help themselves. If they attempt to leave they are guilty of *crimen laesae maiestatis,* and are likely to be burned. It is supported by involuntary contributions, by tithe and by tax. And, it may be added, it claims to override, all the world over, the power of the secular State."

Much of this power came to the Church by a process as legitimate as that which could be claimed by most of the civil Governments. The Church had consciously modelled her organization on that of the Roman empire; and she survived when the empire went to wreck. At first there was no question of serious rivalry with the earthly state. Gregory I., in face of an imperial edict or law which he might have been excused for interpreting as a trespass upon Church privileges, had no doubt about his duty of publishing the edict as he was commanded, even while he protested against it; "What am I," he wrote to the imperial council, "but dust and a worm? . . . a man set under authority."

It was only by degrees, and not without many reactions, even under Charles's weak successors, that the popes reached a position which rendered possible the claims of Gregory VII., a man of commanding genius and rare courage. Starting from Augustine's theory of the City of God, founded by Christ, in its contrast with the earthly city, founded by Cain, Gregory insists that the papal power of binding and loosing places him above all earthly sovereigns. It enables him to annul all oaths made contrary to God's will (of which the pope is interpreter) and to absolve all subjects from allegiance to an emperor whom the pope has deposed. Innocent III. (d. 1216) reasserted these claims both in theory and in practice; and at the death of the Emperor Frederick II. in 1250 the long struggle between papacy and empire was virtually decided in favour of the former.

National Spirit.—Yet the papacy now found a more formidable rival in the growing spirit of nationalism, which, no less than imperialism, must necessarily find itself in conflict with a non-national authority claiming moral dictatorship, and therefore political dominion, over the whole western world. It has sometimes been asserted that nationalism was unknown to the middle ages; that the one Church, with one Latin tongue for all educated Europe, effaced merely national divisions. This, however, is a very superficial view. In proportion as the heterogeneous mediaeval populations consolidated into nations, they developed also the consciousness of nationality; divisions became fewer than in the dark ages, but deeper; we may say that the papacy and the Latin tongue had scarcely more to do with the ending of the Hundred Years' War than with its outbreak; and Marsilius of Padua (1324) was on unassailable historical ground when he asserted that popes had very frequently been the authors of European wars.

France was the greatest nation in the 14th century; therefore she was nationally one of the most self-conscious; and it is she who came into directest conflict with the papacy. Boniface VIII.

(d. 1302) attempted to forbid taxation of the clergy by the State; again, he claimed that "all law is enclosed in the casket of the pope's breast." In his bull *Unam Sanctam*, he proclaimed to the world: "We declare that all human beings are subject to the pontiff of Rome; and we assert, define and pronounce this tenet to be essential and necessary to salvation." This attitude led to a conflict with Philippe-le-Bel of France, in which Boniface was humbled; this, again was a prelude to the transference from Rome to Avignon, where the popes in fact, though not in pretension, became virtually subjects of the French king. Even in England, where it might be argued that the clergy themselves were becoming more papalist than ever, and where Archbishop Arundel could proclaim that it was heresy to dispute any papal decretal (1408), yet king and parliament were putting very definite limits to papal control by their Statutes of Provisors and of Praemunire. Other sovereigns presently protected themselves by similar measures.

Publicists.—For, meanwhile, in the first half of the 14th century, publicists like Marsilius of Padua and William of Ockham (*see* OCCAM) enunciated theories which probably represented what a good many thinkers had long since been saying confidentially to each other in universities like Paris, and in great self-governing cities like Padua. For Marsilius and Ockham, the Bible is the great rule of life for Christendom; the supreme power resides in a council of the whole Church, to which Ockham, apparently, was ready to admit women, and which may judge the pope. Indeed, Ockham is ready to conceive a Christendom without the pope; true, there are certain functions which it would be difficult to arrange otherwise, but the papacy is not essential to the Church of Christ. These speculations formed a fitting prelude to the conciliar epoch (1414–57) during which, mainly at Constance (*q.v.*) and Basel, the Church attempted to put definite constitutional limits to papal autocracy. Both councils decreed, and compelled popes practically to admit, that a general council may judge and depose even a supreme pontiff, and that the pope cannot legislate without conciliar approval.

It is true that the constitutionalists here, as in the England of 1642, over-reached themselves, and the later mediaeval papacy profited by a reaction which rendered it despotic again within the Church. But the laity never forgot; and temporal princes grew more and more accustomed to maintain their own interests in open conflict with the pope.

Two factors contributed farther to this political independence. The monastic reforms decreed by the councils of Constance and Basel, in so far as they were carried out at all, owed much of their success to the secular authorities; in this field, at any rate, it became increasingly plain that the Church was not likely to reform herself merely from within. Again, the later mediaeval popes were predominantly politicians. The papacy had become an Italian principate; the pontiffs constantly involved themselves in those civil wars which made Italy a "hostelry of pain" (Dante); and they showed no less selfishness and duplicity than the princes with whom they were contending. They were ready to go any lengths to secure a little more authority or a few more square miles of territory; as when Clement V. (1309) decreed that the resisting Venetians should be sold into slavery, and Gregory XI. and Sixtus IV. decreed the same for the Florentines and Julius II. for both Florence and Bologna. The bull by which Nicholas V. (1442) encouraged Portugal to what became the organized trade in negro slaves did not immediately show these disastrous results; but when, in 1538, Paul III. decreed slavery against all Englishmen who should dare to support Henry VIII. against the pope, nobody was deceived as to the selfishness of this political move. (For evidence on these points *see* articles SLAVERY and INQUISITION; also T. Brecht, *Kirche und Sklaverei*, p. 156.) A quarrel with this spiritual autocrat, however moral or religious might be the original cause of difference, became *ipso facto* a political quarrel. Therefore, in 1500, any spark might have kindled a general conflagration.

Martin Luther.—This spark, when it came, was in fact moral and religious; but it at once kindled the mass of inflammable politico-economic material. The pope was working his indulgences to an excess which strained loyalty to the breaking-point. Berthold of Regensburg, long ago [1250], had complained that "many thousands" went to hell because they thought themselves to have bought absolution from these "penny-preachers." Gascoigne, the great Oxford chancellor [1450], wrote even more strongly, in proportion to the growing evil: "Sinners say nowadays 'I care not how many or what evils I do in God's sight; for I can easily and quickly get plenary remission of all guilt and penalty by an absolution and indulgence granted me by the pope, whose written grant I have bought for 4d or 6d, or have won as a stake for a game of tennis.' " (*Lib. Veritatum*, p. 86; full translation in G. G. Coulton, *Social Life in Britain*, p. 204.)

Then, in 1517, the rupture came. A scandalous archbishop of Mainz promised Leo X. 10,000 ducats as a bribe for permission to hold three archbishoprics at the same time. This money was to be paid in part from the sums which here, as everywhere else, were being raised by the sale of indulgences for the building of St. Peter's at Rome. An Augustinian friar and university professor of Wittenberg, Martin Luther, expressed the general indignation by drafting 95 theses on the indulgence system, on which he challenged dispute with all comers.

We may say "the general indignation," for Germany was thoroughly prepared for this revolt. She had many flourishing cities, and a high general level of education for that time; the printing press had long been active; several editions of the vernacular Bible had been published, and very many little books of popular piety. The Greek and Latin classics were being studied busily, and in a far less pagan spirit than in Italy. The Inquisition, again, was comparatively inoperative in Germany; there was little chance of its nipping any doctrine in the bud before it had time to gain popular support. And, lastly, the weakness of the central Government was favourable to Luther; it was the patronage of a few local princes that sheltered his movement in its first stages.

GERMANY

The political complications were here very great; the empire contained more than 300 separate states, small and great, which often rendered little more than nominal obedience to the emperor. Luther was first summoned to Rome and then commanded to present himself before the papal legate at Augsburg (Oct. 1518). Finding that the legate practically demanded submission without discussion, Luther published his account of the interview as an appeal to the German people (*Acta Augustana*). Leo X. then sent an envoy, Miltitz, who was so tactful that a reconciliation might conceivably have been effected but for the Leipzig disputation on the papal primacy and supremacy (June 1519), to which Luther was challenged by the Dominican friar Johann Eck. Luther, in his months of preparation for this debate, discovered how many forgeries there were among the documents which seemed to tell most against him; and Eck, by driving him to the admission that not all the tenets of the Hussite heretics were wrong, widened the breach still farther. The younger university teachers were now on Luther's side; and, encouraged by the growing approbation of all classes among the laity, he began to appeal unhesitatingly and unceasingly through the pulpit and the press.

In three great treatises (1520) he took up a position from which he never after retreated on any essential point. For he had a positive programme; a national Church, free from papal interference; inspection of monasteries; limitation of holy-days and pilgrimages, and marriage for the priesthood as the best remedy for the standing disgrace of concubinage.

Leo X. met this programme with a bull (*Exsurge Domine*, June 1520) in which he condemned 41 propositions attributed to Luther. One of these is all the more significant because the condemnation was repeated in other papal letters: Luther had said "It is against the will of the [Holy] Spirit that heretics should be burned." The pope condemns even the least harmful of these 41 propositions as "scandalous or offensive to pious ears or calculated to lead simple minds astray": those who hold or preach any of them are henceforward excommunicate and liable, unless they repent, to all the pains and penalties of heresy. This bull was entrusted to Luther's enemy Eck; but it overshot the mark. Universities and bishops would not or dared not publish it, and

Luther received encouragement from many quarters.

He was now excommunicate, and his writings were solemnly burned; he retaliated by burning the papal decretals with equal publicity. Luther had great virtues and great faults; but at this crisis even his faults had a value for the world; for his courage and self-assertion precipitated the crystallization of a thousand thoughts and impulses with which society had gradually become saturated, but which had remained in solution until now.

This Church quarrel now became the most burning question in all German politics. The young Emperor Charles V. was crowned in Oct. 1520, and fixed January for his first Diet, at Worms. He had followed the fight, and was determined to uphold the traditions of his ancestors. The princes insisted that Luther should not be placed under the ban of the empire without being heard in his defence; he was therefore summoned under a safe conduct. He decided to go, "even though there were as many devils at Worms as tiles on the house-roofs." Nearly 2,000 people came out from the city to welcome him. He was brought before the Diet (April 17) and asked whether he would retract his books and their contents; he requested a day to consider his answer. His reply on the 18th was clear and decided: "The duty that I owe to my Germany will not allow me to recant." Pressed still farther: "It is impossible for me to recant unless I am proved to be in the wrong by the testimony of Scripture or by evident reasoning." Pressed farther again, while the torches began burning down to their sockets, as to the infallibility of general councils (the infallibility of the pope was not yet a necessary article of faith) he replied that these had sometimes erred by contradicting Holy Scripture, and he could prove it. At this, the emperor made a sign to break up the meeting.

The Credo of Charles.—Next day Charles read to the diet his own profession of faith; he stressed the authority not of popes but of councils; and upon that he was firm; here is a single friar now setting up his private judgment against 1,000 years of Catholicism, and "I have therefore resolved to stake upon this cause all my kingdoms and lordships, my friends, my body and my blood, my life and my soul." He called upon the diet to help him in this crusade; but "many turned paler than death." For the antagonism was here clearly stated; Luther was ready to stake all upon his own personal convictions, and the emperor upon his own loyalty to tradition. Here, then, was the clear parting of the ways. Both sides relied, fundamentally, upon the Bible. St. Thomas Aquinas had been as convinced as any later Protestant theologian that the Bible was inerrant not only in its spiritual teaching but even on matters of historical fact.

Authority and Judgment.—The real question which had gradually grown up during the Christian centuries, and which had now come to a point, was not as to the infallibility of the Bible but as to the methods of interpretation: was the book sufficient in itself, with no light beyond God's grace and the earnest searcher's conscience, or could it be rightly interpreted only in the light of ancient tradition, and by certain divinely-constituted teachers who, whenever they met in solemn conclave, were inerrant? Luther, in asserting that general councils had sometimes contradicted the Bible, had thrown down the gauntlet; at that point the emperor had naturally dissolved the assembly but only to take up the gauntlet solemnly next day; if the princes then turned pale, it was because they saw war imminent, and knew neither where it would end nor even (in most cases) on which side they must range themselves. To many, it seemed impossible to accept the existing constitution of Church and society as sacrosanct, to the extent of condemning all radical reform as sacrilegious, and all radical reformers as faggots for the stake.

Yet, on the other hand, they saw how intimately this treatment of nonconformity as heresy, this distrust of free discussion, and these methods of physical coercion, had grown into the whole social fabric, and therefore how great was the fear lest the edifice should collapse if once a friar were allowed to publish his own biblical interpretations against those of the councils, and to persuade the community that the burning of heretics is against the will of the Holy Spirit. Therefore, in the struggle that now follows, all other questions, however important in themselves, are subordinate to this one fundamental antithesis between authority and private judgment. Did the princes desire a world in which the deposit of faith might safely be entrusted to the reason and religious feeling and good sense of the majority, or must physical force be held over men's heads everywhere and always as a menace, and be very frequently employed in fact? Were most men so firmly assured of the fundamentals that all contrary pleas of a small minority might be mainly left to work out their own confusion (as in More's *Utopia*) or was orthodox assurance so wavering that the centre of gravity might shift under the shock of a friar's contradictions, and the Church might turn upside down, and the State with it? The risk was plainly enormous; here was Luther, willing to take that risk for himself and for the world; but few of the politicians could have faced the crisis without serious misgivings.

The Wartburg.—No compromise between Luther and the emperor was now possible; on the 26th, it was announced that his safe-conduct would expire in 21 days. He left Worms; but he was seized by the advice and with the connivance of the elector of Saxony, and carried off to the elector's castle of the Wartburg near Eisenach. The emperor signed Luther's condemnation as a pestilent heretic (May 26); but his secretary wrote to a friend in Spain: "I am persuaded this is not the end, but the beginning. . . . Since [the Emperor's edict], Luther's books are sold with impunity at every step and corner of the streets and market places."

Luther spent nearly ten months in hiding at the castle of the Wartburg, his "Patmos," as he afterwards called it. Here his pen was unceasingly busy with controversial pamphlets and his translation of the New Testament. But his body suffered from want of exercise, and his mind from natural doubts; could so many past generations and so many estimable contemporaries have been wrong, while he, the mere friar, was right as against them all? Might he not be dragging thousands down to hell with himself? Yet his convictions constantly returned more strongly than ever; and, by a natural reaction, he felt increasing confidence in his divine commission; to doubt of this, or to remain treacherously silent, would be to incur damnation. The gulf between authority and private judgment was thenceforward too wide to be bridged; and Luther emerged from the Wartburg as a determined revolutionary. Yet he was a conservative revolutionary; and this it was which brought him out of his retirement.

His doctrines had been spreading widely; the statistics of the German press are most eloquent here; in 1517 only 37 vernacular books were printed; in 1518 there were 71, and by 1523 the number had risen to 498, of which 180 were by Luther himself. For here was a population which, far beyond all others in Europe, had already been gaining a certain familiarity with the Bible in the vernacular. Fourteen editions in High German, and four in Low German, had appeared before 1518; and, though these editions were doubtless limited and therefore expensive, yet they must have done something to permeate popular thought. Most of the great cities were becoming Lutheran; the new doctrines spread, naturally enough, in Luther's own religious order (the Austin Friars) and in his University of Wittenberg.

Here, in fact, things went too fast. One of the Wittenberg professors, Andrew Bodenstein (Carlstadt), pushed matters to extremes; he lectured and preached and wrote against almost all the traditional ceremonies.

Momentum.—At the same time, and only 60 miles away, the populous weaving centre of Zwickau was in still greater religious commotion; three of the Zwickau enthusiasts came to Wittenberg, and Carlstadt persuaded the magistrates to publish an epoch-making ordinance, which practically transferred the whole direction of Church affairs to the laity, who at the same time undertook the poor relief and the moral discipline of the city. Carlstadt went even farther, and started an iconoclastic crusade. Luther's friend and colleague Melanchthon (*q.v.*) disapproved strongly, but could do nothing. The elector also was seriously troubled; other princes were taking the Wittenberg disturbances as a text for armed intervention; and Luther risked his own personal safety to return and restore order. He preached at Wittenberg on eight

successive days: "I will preach reform, I will talk about it, I will write about it, but I will not use force or compulsion with any one. . . . The word will drop into one heart to-day, and to-morrow into another, and so will work that each will forsake the mass."

A new pope came to the throne in 1522, Adrian VI., a pious man sincerely anxious for reform. At the diet of the empire held at Nuremberg (1522–3) his nuncio pressed that serious measures should be taken against Luther, since Charles V.'s decree, however decisively worded, was practically a dead letter. The members of the diet answered by presenting a list of 100 grievances against the Church; the nuncio reported to the pope that "among a thousand men scarcely one could be found untainted by Lutheran teaching." Then Adrian died suddenly, and was succeeded by Clement VII., a Medici by birth and by nature interested less in reform than in papal prestige. His legate, Campeggio, though a most dexterous diplomatist, could effect very little. The Diet of Speyer (1524) began to plan a Church council for Germany, which would have separated from Rome and anticipated England in the formation of a national Church.

The Peasants' War.—It is from this moment that we must date "the beginning of the separation of Germany into two opposite camps of Protestant and Roman Catholic, although the real parting of the ways actually occurred after the Peasants' War" (T. M. Lindsay). That war, though precipitated by the Lutheran revolt, was essentially a mere continuation of the struggles described above. Luther's message was democratic; his language displayed the defects of his qualities; its extraordinary force and directness constantly tempted him into exaggeration, and added fuel to the social discontent which had smouldered for generations side by side with anti-clericalism.

Seven years after Luther's attack on the indulgence system, the peasants' revolt broke suddenly out (June 1524). It began on the upper Rhine, encouraged doubtless by the successful assertion of freedom by the Swiss. In a few weeks the conflagration spread as far north as the Harz, and eastward to Tirol and Styria; cities, knights, and even princes made terms with the insurgents or joined their ranks. But the want of efficient leadership and discipline soon made itself felt; other princes and knights, with trained soldiers at their back, beat the insurgents in one battle after another, and the main revolt was subdued before the end of 1525, leaving the peasants in a worse plight than before, though the Tirolese held out longer and gained real concessions. Luther at first had sympathized with the insurgents and protested against harsh measures; he even risked his life by going among them and preaching peace and moderation.

But soon their excesses angered and dismayed him; his tract *Against the murdering, thieving hordes of peasants* breathed fire and slaughter. Its pitiless tone may be explained, though never excused, by the disastrous reaction of this social revolt upon Luther's own revolution; the more so, since the rebels had in nearly all cases claimed religious sanctions for the movement. It was thenceforth evident that the Reformation was bound to emphasize political and social differences. Hitherto it might have been called a national movement in Germany, but henceforward it was a party-question in every sense of the word.

A Religion of State.—The story is complicated by the multiplicity and kaleidoscopic changes of these 300 German States, and especially by the confusion between the two Saxonys. Catholicism and Protestantism were exposed to all the gusts of party politics. In Luther himself the prophet often gave way to the politician; and he, who in 1525 had at first insisted that the peasants must be met not with blows but with reasons, was soon ready to call upon secular princes to draw the sword against all enemies of the Reformation. He had begun by insisting on responsibility to God alone; but now with most of the Reformers, he ended by subordinating Church to State. In July 1525, a league of Catholic princes was being formed to quench the Reformation in blood; in October, the landgrave Philip of Hesse began to frame a defensive league of Protestant princes. This support could be bought only by abandoning absolute freedom of private judgment and by allowing many ecclesiastical endowments to be secularized. In order to avoid offending the landgrave, Luther, Melanchthon and Bucer agreed in allowing him to commit bigamy; a concession which may be paralleled by a few similar licences from popes, but which, coming from these Reformers, justly scandalized the public more than the papal actions. On both sides, Catholic and Protestant, self-interest now played a very great part.

The ups and downs may be very briefly summarized. The Diet of Augsburg (Dec. 1525) did little. That of Speyer (June 1526) refused to execute the edict of Worms, and procured the decision that each prince should so act in matters of faith as to be able to answer for his conduct to God and the emperor. This gave the Reformers a most valuable breathing space, but the Catholic States were presently provoked into organizing persecution against heretical subjects; the emperor, having now made up his private quarrel with the pope, was determined to fight the innovators, and a diet at Speyer (1529) altered the tolerant decree of 1526. Six princes and 14 cities read a solemn protest at the diet against this vote; and the action of this small minority gave to the party that name of Protestant by which it has ever since been known.

Schmalkalden.—For the Diet of Augsburg (June 1530) Melanchthon drew up a confession, which minimized the differences between Lutherans and Catholics, and exaggerated those which separated Luther from the more radical Swiss reformer Zwingli. The emperor granted a respite till April 15, 1531. By that date, eight princes and 11 cities had formed at Schmalkalden a defensive league for six years. The emperor, more and more hampered by the Turkish peril, finally granted the Peace of Nuremberg (July 1532) which guaranteed the Protestants from molestation until the next general council of the Church. But Clement VII. was in no haste to call such a council; he feared the emperor's encroachments scarcely less than Luther's heresy; and, meanwhile, Protestantism gained much ground, though in Switzerland it had received a check in the death of Zwingli. When at last the general council, in spite of dissensions among the orthodox, seemed imminent, the Protestant princes refused to attend it; they renewed the Schmalkaldic League (1537) and were joined by fresh allies. The emperor formed a counter-league (Nuremberg, 1538) and war seemed imminent, when a compromise was arranged at the Diet of Frankfort (1539).

A series of conferences, from 1540 onwards, produced no real agreement. In 1544 the Peace of Nuremberg was formally prolonged for another five years; but the continual spread of Protestantism, not always without a violence equal to that which their enemies were prepared to exercise, precipitated a struggle. The long-delayed council of the Church had at last met (Trent, 1542); but the Protestants refused to attend it. The emperor declared war; the Protestants were beaten at Mühlberg (1547), and promised to send representatives to Trent, but were freed from that undertaking by Catholic dissensions. At the Diet of Augsburg (1548), Charles drew up on his own responsibility a sort of compromise, the *Interim;* and in 1551 the Protestants sent representatives to Trent.

But the Interim was naturally unpopular on both sides; and, next year, Maurice of Saxony took advantage of the emperor's twofold embarrassments with France and Turkey to turn suddenly against him; he almost succeeded in taking him prisoner. Charles, foreseeing defeat and shrinking from the humiliation, soon transferred to his brother Ferdinand of Austria the direction of German affairs (1554). Maurice was killed in the moment of victory at Sievershausen; John Frederick of Saxony died soon afterwards; but Protestantism was too deeply rooted to be shaken.

"Cuius regio, eius religio."—While the Diet of Augsburg was hesitating to grant religious peace, a rival assembly at Naumburg was attended by more princes than the diet itself, and decided to abide by the confession of Augsburg (1555). (*See* AUGSBURG, CONFESSION OF.) The diet, after many struggles, agreed to one of those compromises which leave seeds for future war. It consecrated the principle *cuius regio, eius religio;* each prince might choose for himself between Catholicism and Protestantism; his subjects must submit to that choice unless they preferred to emigrate. We must here end the story of the Reformation in Germany. The mere fact that Catholicism had been compelled, over and over again, to negotiate with Protestantism on something

like equal terms, was a death-blow to the mediaeval conception of the Church. Now, by this Peace of Augsburg, Protestantism was actually legalized for about half the population of Germany; and this proportion has since maintained itself with little alteration.

SWITZERLAND

Switzerland had broken loose from the empire in 1499; and here was plenty of fuel for Luther's spark. Ulrich Zwingli (b. 1484) was ordained priest in 1506 and soon distinguished himself as an opponent of moral abuses both in the Church and among the laity. In 1518 he succeeded in expelling the indulgence-seller of St. Peter's from the canton of Schwyz; and was promoted to the great minster of Zürich. Here his learning and zeal, aided by the strongly democratic tendencies of this city of Zürich, made him into a combination of prophet, priest and politician. The burghers of Zürich had long exercised a disciplinary control over their clergy which was far from usual; and here also was an important printing press. Zwingli, in his campaign against the wholesale enlistment of young Switzers as mercenaries for foreign countries, was bold enough to preach also "that it is no sin to eat flesh on a fast day, though it is a great sin to sell human flesh for slaughter." This brought him into conflict with the bishop of his diocese (Constance). In 1522, by a custom general among the Swiss clergy, he contracted a connection with the widow of a citizen, and joined with ten other priests in a petition to the bishop against the law of celibacy, on the ground that this was commonly broken in Switzerland. In April 1524 he married her publicly, in defiance of the Church.

Meanwhile the magistrates had arranged a public disputation between orthodox and innovators (Jan. 1523). More than 600 clergy and representative laity attended, and the magistrates decided in Zwingli's favour. In consequence of a second disputation in the autumn, all church pictures and images were abolished; presently the monasteries were disendowed, and their funds devoted to schools and the poor. The neighbouring canton of Lucerne sent to warn Zürich against its heresies; threats were added, and Zürich began to prepare for war. In 1525 a new form of liturgy was prescribed, severely puritanical; and in 1529 the Catholic worship was forbidden.

Division.—Meanwhile the revolt spread to other cantons. At a disputation at Baden (May 1526), which Zwingli refused to attend, 82 clerical representatives voted for the conservative side, as against 20 reformers. Yet the movement went rapidly forward, in spite of Zwingli's quarrel with the more conservative Luther, and of the set-back which followed here, as in Germany, upon the Peasants' Revolt. The forest cantons, with their comparatively primitive and scattered peasantry, were naturally on the conservative side; they had formed an anti-heretical league (April 1524); and in Zwingli the prophet became more and more overshadowed by the politician. Between 1527 and 1530 Zürich succeeded in creating a league of the greater Protestant towns, to which the five forest cantons replied by a "Christian Union" (April 1529). Each party was ready to ally itself with the foreigner; Zürich with France, the Union with Austria. The Swiss confederacy was thus broken up into two opposing camps. The Catholics were unable to accept the full principle of mutual tolerance; and Zürich also was aggressive and intolerant. The two armies faced each other at Kappel, but peace was patched up (June 1529). This was only a truce; they met again at Kappel, where Zwingli was defeated and slain (1531). The peace now made granted to each canton the choice of its own religion, and did much also to protect minorities. The country soon settled into much the same division which still obtains: Catholicism reigned mainly in the mountains and Protestantism in the more fertile lands and in the great cities.

Geneva.—Geneva (not yet in Switzerland) deserves separate mention: it owed everything to its neutral position and to the personality of John Calvin (*q.v.*). The Genevese had lived for centuries under a prince-bishop, though with a good deal of democracy in their civic constitution; thus State and Church were more closely interwoven here than in most other cities.

In 1530 the city rebelled against its bishop; in 1534 it entered into a contract for joint citizenship with Protestant Berne; in 1536 it formally committed itself to Protestantism, and two months later Calvin settled in the city. He was a man of precociously wide and exact scholarship, bred in the law, and touched with inspiration from Erasmus and Luther at the age of 24 (1533).

Calvin's "Institution."—Next year he fled from France; in 1535 he was at Basel, where he wrote in Latin his *Institution of Christian Religion*, which he afterwards turned into French. This epoch-making book has often been misrepresented. Calvin's insistence upon the torments of hell is merely the orthodox mediaeval doctrine, in a far milder form than we find it (for instance) in St. Bernardino of Siena. His insistence upon predestination does not go far beyond St. Thomas Aquinas, whose actual words are often softened down by his modern exponents. The great value of Calvin's book was that it gave a clear and logical structure to a hitherto formless and disorganized Protestant thought, much as St. Thomas and his fellows had constructed a logical synthesis from the heterogeneous mass of Catholic traditions.

In July of 1536 Calvin passed through Geneva, where the reformer Guillaume Farel persuaded him to stay. He introduced into the city, now an independent republic, a discipline which, like his *Institution*, may easily be misunderstood. His supervision of morals and expenses and amusements was no new thing; there is practically no detail in that field which had not been insisted upon by orthodox mediaeval theologians for centuries past, and written in town statute-books, and sometimes even enforced in practice. Here, Calvin's innovation was to substitute stern regularity for impulse and caprice. For the matter was now in the hands of business men; the bishop having been driven out, this enforcement of discipline devolved upon the town council as wielders both of ecclesiastical and of secular authority.

And behind that was another revival from the past. Anxious as Calvin was to revert to the Christianity of the earliest days, and finding as he did in the Lord's Supper the central Christian rite, he insisted on the rejection of unworthy communicants. This regulation proved too stringent for many others besides the "libertines"; and Calvin, with his two chief colleagues, was banished in 1538. The city recalled him in 1541, and he obeyed, most unwillingly, for the sake of what he regarded as a great public work. His *Ecclesiastical Ordinances* and his institution of the *Consistory*, became in one sense the parents of Presbyterianism (*q.v.*). The discipline which had always been advocated was now actually enforced; and nonconformists were punished, sometimes even to the death; the world will never forget how this rebel Calvin burned the Unitarian Servetus. But he saw that a Protestant ministry could never hold its ground without solid learning; therefore he wrote a catechism which should teach even children to give reasons for their faith; moreover, he founded a grammar-school and an academy which attracted able men from all lands, and which sent missionaries out in all directions.

FRANCE

In France, as in Switzerland, the germ of the Reformation is pre-Lutheran. The concordat of 1516 had put the French Church practically under royal authority; the Renaissance (*q.v.*) was rapidly sapping mediaeval conventions; and one very remarkable man devoted himself with equal enthusiasm to religious reform and to learning. This was Jacques Lefèvre (Faber Stapulensis), who in 1512, at the age of about 55, published a Latin translation of the Pauline epistles, with a commentary which roughly anticipated Luther's theory of grace and his denial of transubstantiation. In 1524 Lefèvre revised a French translation of the New Testament, as a foretaste of the whole Bible. He was now under the protection of his old pupil Briçonnet, bishop of Meaux, who had set his heart on the reformation of morals and religion within that diocese. With the help of other pupils, such as Guillaume Farel, Lefèvre created a whole school of students and evangelical preachers.

Meanwhile Luther's doctrines were spreading in France and had been formally condemned (1521); and in 1523 the bishop of

Meaux found himself obliged to fulminate against Luther by name, and against certain doctrines held by Farel and other extremists. Then the *parlement* took strong measures against the innovators: Lefèvre's Testament was burned, while he and his friends found safety in flight. Heresy spread rapidly, and Francis I. favoured or punished it according to the changes of the political weathercock. At the end of 1533 he decreed instant burning against any man convicted by two witnesses of being a Lutheran; but the next January he signed a secret treaty with the Protestant princes of Germany.

Then the excesses of the wilder reformers, who placarded Paris with an offensive broadside against the mass and the priests, caused a natural reaction among the people and at court. In two months, nearly 200 heretics were in the Paris prisons, and eight had been burned. When Lefèvre died (1536) "partly from the timidity of the leaders and partly from the rashness of the rank and file, the first or Evangelical phase of Protestantism in France had failed to bring about a reform of the Church" (A. A. Tilley in *Camb. Mod. Hist.*, vol. II.).

In that same year Calvin published his *Institution*, with which the second, or Calvinistic, phase began. The book supplied the Protestants with a clear and detailed theory of religion; on the other hand, it involved a considerable recoil from two most important principles: it set definite limits both to free enquiry and to individualism. Thenceforward French reformers shared the strength and the weakness of institutionalism. More truly in France than in any other great country, Geneva now became "the Protestant Rome."

The Waldensians.—After a lull, persecution became more severe again (1538–40). The theological faculty of Paris drew up 26 articles of faith in answer to the *Institution*, which Calvin had now published in French, and which was solemnly burned in 1544; meanwhile, many Calvinists were burned here and there. In 1530, the Waldensians (Vaudois) who had survived from mediaeval persecutions in a group of 30 remote mountain villages along the Durance, affiliated themselves to the Lutherans; therefore in 1545, after varying negotiations, an army was sent against them without warning; 22 villages were burned and 3,000 men, women and children were killed.

A still deeper impression was made by the *auto-da-fé* of Meaux (1546) because this was a solemn and judicial act. Sixty persons were here arrested for the crime of having celebrated the Lord's Supper in Protestant fashion; all but ten were punished; 14 were tortured and burned. Even this did not drive the new doctrines altogether underground; other executions took place elsewhere; but meanwhile missionaries and pedlars were secretly preaching and distributing forbidden pamphlets in every province except far-off Brittany. After ten years of this, Francis I. died, and Henry II. sharpened the persecution, by creating an anti-heretical committee of the *parlement* of Paris, which became known as the *chambre ardente*. This condemned at least 100 persons to death in 3 years; and the provincial *parlements* followed suit.

Yet Protestantism still grew; and in 1555 it began to organize itself; churches were founded on the model which Calvin had framed for Strassburg, and in 1559 a General Synod met, representing from 40 to 50 churches. The Government now procured papal approbation for an Inquisition after the Spanish model; but the Paris *parlement* was not prepared to go so far. Meanwhile the new doctrines were taken up by some of the higher nobility; they thus acquired the advantage and the disadvantage of becoming both fashionable and political. The execution of a distinguished member of the *parlement*, Anne du Bourg, for merely protesting against persecution (1559), could be described by an eyewitness as "doing more harm to the Catholic Church than 100 ministers could have done." But the "tumult of Amboise," next year, redressed the balance. The Government, during the boyhood of Francis II., had fallen into the hands of the Guise family; and a number of Protestant nobles conspired at Amboise to arrest and imprison these unpopular rulers. The plot failed and brought natural discredit upon the religious cause.

A Political Party.—Protestantism was now becoming almost as definitely a political party in France as Catholicism; therefore, a council was held at Poissy, virtually representing the whole nation, to find a *modus vivendi* on the basis of mutual toleration. The Protestants were represented by 12 ministers and 20 laymen; the Catholics by six cardinals and 64 prelates or doctors; the king presided, with the queen mother and princes of the blood. The conference failed to effect a compromise between irreconcilable doctrines; but it was followed by an edict granting liberty of conscience within certain definite limitations. This, however, without fully satisfying the Protestants, was enough to exasperate the Catholics.

In March 1562, the former were holding a religious service in a barn at Vassy, in spite of the edict which forbade their worship in any walled town. The duke of Guise, passing through the town, sent his men to expel them. They resisted, and the soldiers stormed the barn, killing 63 of the worshippers and wounding 100 or more. The example of this "massacre of Vassy" was followed in many other places; henceforward the Wars of Religion begin, and we can no longer treat the French Reformation as a purely spiritual movement. The massacre of St. Bartholomew was a natural sequel to the tumult of Amboise and the massacre of Vassy. But, before quitting this subject, we must note that the "Presbyterian" constitution owes even more, directly, to the French Protestants than to any other source. Their "confession of faith" and their "book of discipline," though founded essentially upon Calvin, have more directly influenced the Dutch, Scottish and American churches, than Calvin's own constitution at Geneva.

THE NETHERLANDS

When we have thus followed the German, Swiss and French Reformations, we find little that is new in other Continental countries. The Netherlands were well prepared for Protestantism by their busy civic life, their early welcome of the printing-press, their vernacular translation of the Bible (1477), and the educational work of the *Brethren of the Common Life* or *Common Lot* (*q.v.; see* also GROOT, GERHARD). Luther's writings were welcomed at once; and the Bible was frequently printed in Dutch, Flemish and French between 1513 and 1531.

Charles V. began with public burnings of Lutheran books *en masse*, and then established the Inquisition (1522). Burnings for heresy began early; but the emperor's edicts, though severe and frequently repeated, were difficult to enforce in face of the growing opposition. Special severity and peculiar tortures were reserved for the Anabaptists, who were intercepted and slaughtered in large numbers even when they attempted to emigrate. At last, in 1534, they were provoked to strike back, but with the natural result of severer persecution. Under Philip II., political and religious oppression were intertwined. When, in 1565, he insisted on the publication of the decrees of the Council of Trent, not in the pope's name but in his own, Holland and Brabant protested against this as an infringement of their constitutional liberties. Next year, a confederacy of nobles and leading citizens pledged themselves to resist the Inquisition, and adopted the nickname of *Gueux* (*q.v.*) which the courtiers had fastened upon them.

In July, Philip promised to withdraw the Inquisition and grant such tolerance as his conscience would permit; but the secret archives of Simancas show that he wrote simultaneously to the pope and explained this promise as a mere ruse to gain time. At that point, a series of iconoclastic outrages by the Protestant mob gave a legitimate handle to the Catholics. The duke of Alva was then made vicegerent by Philip II.; he proclaimed heresy as high treason and inaugurated a reign of terror (1567); from that time forth the struggle became political; religious discussion was merged in civil war.

DENMARK AND SWEDEN

In Scandinavia the revolution was comparatively bloodless. King Christian II. of Denmark imported a Lutheran preacher in 1519, and would have welcomed Luther himself; he published new codes of law which no pope could approve. But he became unpopular, fled from his kingdom in 1523, and was reconciled to the

pope in 1529. Meanwhile Frederick I., proclaimed as his successor, made peace with the clergy; but Lutheran doctrines still spread; and, Frederick believing himself to have been tricked by the pope in the matter of the archbishopric of Lund, was confirmed in his own growing inclinations towards Protestantism.

His son Christian and his son-in-law Albert of Brandenburg had already declared themselves and in 1527 Frederick met the solemn remonstrances of the bishops with the reply that faith is free, and that each man must follow his own conscience. In 1530, 21 Lutheran preachers, accused of heresy, offered to dispute publicly in Danish against the accusing bishops, who, however, refused to discuss religious questions in the vernacular. Frederick's son Christian III., in 1536, abolished the bishops' authority, seized their possessions, and imported a disciple of Luther, Bugenhagen, as his chief ecclesiastical adviser. Much of the ancient ritual was preserved; and, though there was inevitable friction between the two parties, this systematic and authoritative change of official religion avoided civil war, and brought Denmark higher in commerce and in learning than she had ever stood before. Frederick and Christian made corresponding changes in their subject lands of Norway and Iceland; but here the ancient abuses had been less crying; the people were less ready for change; so that the revolution thus forced upon them from above caused perhaps as much evil as that which it professed to remedy.

In Sweden also the royal initiative secured a bloodless change. Gustavus Vasa (1523–60) had made the acquaintance of Lutheran preachers before his accession; and political necessities led him to look towards disendowment of the Church. A public disputation in the king's palace (1524) went in favour of the reformers; between 1526 and 1541 the whole Bible was published in the vernacular; and men could henceforth judge better for themselves between the rival claims. The diet of 1527 decided in favour of Lutheranism and disendowment. The next king showed some preference for Calvinism; and John III. (1568–92) proposed reunion with Rome. John's son had adopted Catholicism; therefore the people resolved to secure themselves before his formal accession. A synod of lay folk and clergy was held at Uppsala; it decided to accept the bible as the supreme authority, adopted the Augsburg confession, and restored Luther's catechism as the foundation of all religious teaching.

ITALY AND SPAIN

In Southern Europe, in Italy and Spain, Protestantism enjoyed no princely protection of any importance, nor (perhaps on that account) did it ever spread far enough to gain a hold upon the people. Here, as elsewhere, orthodox reformers constantly fell under suspicion because orthodoxy and radical reform were so difficult to reconcile in practice. The celebrated *Counsel for Amendment of the Church*, drawn up in 1537 by a papal commission of cardinals and other distinguished theologians, insisted that dispensations from Church law should not be so frequent, and should never be given for money. Yet one of these same cardinals, Caraffa, when raised to the papacy as Paul IV., condemned the document in 1559 to his Index of Prohibited Books, while three of the other cardinals (Sadoleto, Contarini and Pole) fell under suspicion of unorthodoxy in later years. Many Italian reformers were thus driven over the line; others protested their loyalty to the last.

The Triumph of Orthodoxy.—The Inquisition, in both countries, was a deciding factor. Into Italy it was reintroduced in 1542 by Cardinal Caraffa, who, when raised to the papacy, worked it with increasing severity. Although Naples and Venice refused to grant it full powers, yet, even there, it was strong enough to prevent any real organization of Protestantism; while in the principalities of Ferrara, Modena and elsewhere heresy was always struck down before it could mature; at Modena 14 persons were burned in the single year 1568. Many fled abroad; in Switzerland there grew up a considerable Italian community; some of these, persecuted by Calvin for their extreme radicalism, fled into Poland and contributed to the spread of Unitarianism.

In Spain, orthodoxy triumphed still more easily. Cardinal Ximenes (d. 1517) had, by the most drastic disciplinary action, raised the Spanish clergy far above the general European level of morals and learning: consequently there was a strong party which could accuse even Erasmus of wild exaggeration in his attack upon Church abuses; distinguished men were condemned for favouring "Erasmic" propositions. Secret communities of Protestants gradually formed at Seville (where we are told of nearly 1,000 members) and at Valladolid. But two *autos da fé* (1559–60) burned 24 men and women at Seville; two others (1559) burned 27 at Valladolid; there were other sporadic executions, and the Spanish non-conformists, like the Italian, could find safety only in flight. In Portugal, where the Inquisition was even more rigorous, we can scarcely guess what might have been the result if anything like private judgment had been possible for the people; what actually happened was that the country produced very few Protestants.

GREAT BRITAIN AND IRELAND

The English story is peculiar in one most important particular. In its beginnings, the Reformation was strongly political, yet not anti-Catholic; Henry VIII.'s ideal was "the papacy without the pope."

Here, as in Germany, the ground was well prepared. Lollardy had been driven underground; but it was still very far from complete extinction. The clergy were, on the whole, unpopular, especially in London. The bishop of London wrote to Wolsey in 1515: "Assured am I, if my chancellor be tried by any [jury of] 12 men in London, they be so maliciously set in favour of heretical pravity that they will cast and condemn any cleric, though he were as innocent as Abel." And Charles V.'s envoy, Chapuys, reported to his master from London in 1529: "Nearly all the people here hate the priests." Here, therefore, as in many other parts of Europe, the mediaeval concordat between Church and State was already breaking down.

And here also the Renaissance had already begun to undermine the old fabric. In 1516, More told Erasmus that the *Epistolae Obscurorum Virorum*, a bitter satire upon the monks and the traditional philosophy, was "read everywhere" in England. Erasmus's own writings had enjoyed great popularity; and Colet, dean of St. Paul's, supported the new learning against tradition with a boldness which naturally started other men upon still bolder courses; moreover, More's *Utopia*, published in 1516, was almost as revolutionary on the theological as on the social and political side. All religions are tolerated in Utopia, and almost all religious discussion. For in this country "nothing is seen or heard in the churches, but that which seemeth to agree indifferently with them all. If there be a distinct kind of sacrifice peculiar to any several sect, that they execute at home in their own houses." Wider knowledge of the universe was beginning to break down that mediaeval condemnation of all non-Christians to hell; and this breakdown must, sooner or later, involve a break with yet other mediaeval tenets.

The "Defender of the Faith."—Therefore, when Luther came forward, his works found an early welcome in England; and in 1521 Henry wrote a Latin treatise against the heresiarch which earned him from the pope the solemn title of "Defender of the Faith." Heretical books were burned in St. Paul's churchyard, and four heretics were burned in the diocese of Lincoln, while 50 more abjured their creed. But Lutheran groups began to form at the two universities, especially at Cambridge; which produced eight leaders of the new movement. Here, in 1525, the prior of the Austin Friars, Dr. Barnes, preached a sermon which caused his prosecution for heresy; he was compelled to abjure at St. Paul's, in company with four German merchants. But, a year later, the king was planning a divorce and remarriage, since it was politically necessary for him to have a definite heir to the throne.

This has often been represented as a mere piece of sensuality; but the facts speak plainly to the contrary. There was nothing to prevent Henry, if he had wished it, from keeping a harem like those of his contemporary Francis I. in France and his successor Charles II. in England. Moreover, before the question of Catharine's divorce came up, Henry was already taking very strong measures in another direction; he heaped honours upon his one

known illegitimate son, Henry Fitzroy, and planned, with the advice of his council, the proclamation of this six-year-old boy as heir to the throne. But the plan broke down and Henry's attachment to Anne Boleyn now contributed to suggest the other expedient of a divorce from Catharine. (In the strict technical sense it was not a *divorce*, but a *decree of nullity*; however, the briefer term was very commonly used then, as since.)

This complicated story may be reduced to a few simple issues. In the minds of all the principal actors except Catharine, the problem was mainly or wholly political. The king needed a male heir; he and his counsellors augured disaster to the kingdom from a female or a disputed succession. So also with Rome; Clement VII. himself was long in making up his mind as to the Catharine case; and, most significant of all, he actually suggested in 1530 that the problem might be solved without divorce, by allowing Henry two wives at once. (A. F. Pollard, *Henry VIII.* [1905], p. 207.) Even if, as some of Henry's advisers suggested, this was merely a diplomatic feint, it is no less significant in this present connection. Henry had thought of the proposal seriously at an earlier stage, and based it upon Old Testament precedents. As Pollard points out, Eugenius IV. had actually granted similar licence to Henry IV. of Castile, for similar political reasons, in 1437. For the pope's real difficulty was not in the moral problem of the Boleyn marriage but in the political problem of the divorce, since Catharine was aunt to the most powerful sovereign in Europe, and the one from whom Clement had most to fear personally. Therefore the pope evaded all definite decisions, shifting in response to the shifting political situation, for three years (1527–29), when at last he transferred the case to Rome.

Then, at Cranmer's advice, Henry appealed to the universities, and, apart from Oxford and Cambridge, eight of the greatest in Europe decided for him (Paris, Orléans, Bourges, Toulouse, Bologna, Ferrara, Pavia and Padua). However much we may discount these verdicts by royal pressure and other evidence which suggests bribery by both parties, yet on the whole "these opinions must stand for the general opinion of the learned, unless the divines of France and Italy were more generally venal than is commonly supposed" (H. M. Gwatkin).

Supreme Head.—Already in 1529 Henry had begun to permit the circulation of anti-papal German pamphlets as a threat to the pope; and had even allowed his envoy to hint at further Lutheran developments. Next year, the bishop of Norwich complained of the impossibility of destroying heretical books so long as many folk believed the king to favour them. But at that very moment Henry was taking public measures against heresy, burning Tyndale's New Testament, and forbidding all English Bibles until a version should be made "by great, learned and Catholic persons." This last (as More confessed about the same time) was a great desideratum; yet no such orthodox version was made, or even attempted until long after England had broken finally with Rome (1582–1609).

Already, in 1529, Henry had begun an attack upon the clergy, probably upon the advice of his new minister, the adventurer Thomas Cromwell. Taking advantage of their notorious unpopularity, Henry considerably curtailed the clerical exactions of which lay folk were complaining, and restricted the evils of plurality and non-residence. It was made a penal offense to evade this statute by seeking dispensation from Rome.

Next year, came a still plainer step. Henry, under form of law and without real justice, condemned the clergy of England for having allowed the papal legate to set up his court in England, in violation of the Statute of Praemunire. He extorted not only an enormous fine, but also an acknowledgment in the convocation of Canterbury that the king is "only and supreme lord [of the clergy], and, as far as the law of Christ allows, even supreme head." But this weapon rested in its sheath until the parliament of 1532.

In this parliament, by means which cannot be palliated except on the plea that they were usual in the politics of that day, and that his adversaries were not more scrupulous, Henry first forced convocation, the parliament of the clergy, to accept three articles which definitely submitted Church to State in England. He then procured from parliament a statute abolishing "annates," one of the most lucrative sources of papal revenue from England: this, however, he held in his hand at first only as a menace to Rome, until he had procured papal bulls of approval for the election of Cranmer as archbishop of Canterbury. Next, he procured a statute declaring the king supreme head of Church and State, and forbidding all appeals to Rome. Then, by a capitulation even more humiliating than the previous "submission of the clergy," convocation, at Henry's demand, declared the nullity of Catharine's marriage. There was a mock-trial of the case at Dunstable, and Henry, who had already secretly married Anne Boleyn, was now free to make her his queen. How he then succeeded in defying papal excommunication, and in preventing any papal crusade being launched against him by the Catholic princes of Europe, is a purely political story. Before parliament dissolved, it passed a statute forbidding all further payments of any kind to "the bishop of Rome," and "an act for the submission of the clergy to the king's majesty."

The rest of Henry's reign was spent in ruthless warfare against heretics who believed in mediaeval Catholicism less than he did, and against others who believed more than he. His "six articles" of 1539 rehearsed nearly all the main points of the mediaeval creed; to deny transubstantiation was made heresy, and therefore punishable with burning; to deny any of the other five was felony. Consequently the king was burning heretics on the one hand, while on the other he was enforcing obedience to the royal supremacy by beheading Fisher and More.

The Monasteries.—Three causes led him to strike at the monasteries. They were pro-papal, wealthy, and not popular enough to find many defenders. Among the few points of importance upon which historians on both sides are agreed, are two which concern us here: that the monasteries necessarily considered their own cause bound up with the pope's and that one of the most remarkable features of Henry's despotic reign is the absence of organized or determined resistance on the part of the clergy, whether cloistered or not. Henry was extravagant; he wanted money; and here was a comparatively easy prey. Everywhere else in Europe, the civil authority had already been obliged to interfere in the cause of monastic reform.

The articles of reform for English monasteries, which Cromwell issued by Henry's orders, do not deserve the blame which has sometimes been cast upon them. Not only the majority of them, but the most important, were taken straight from the Benedictine rule or from the decrees of popes and other orthodox reformers in the past. When, for instance, Cromwell prescribes "that no monk, or brother of this monastery, by any means go forth of the precinct of the same," he is here only summarizing the plain prohibition in chapter 66 of St. Benedict's rule. When, again, he goes on to command that "women, of what state or condition soever they be, be utterly excluded," this is one of the most time-honoured and frequently repeated of monastic statutes. The only real novelties in this Cromwellian document are the command to accept and preach royal supremacy, and the freedom given to subject monks to complain against superiors who neglect or contravene any of this long list of injunctions.

But Cromwell's visitation of the monasteries is open to far more serious criticism. He chose base agents, who did their work in a base and hasty fashion. It is quite possible that they invented much of their evidence; yet we have irrefragable orthodox testimony to the fact that this unfavourable evidence did not violate probability. The spoils of the monasteries were devoted partly to public purposes, but mainly to pay Henry's courtiers: here England compares very unfavourably with Scotland and some of the German states, where the money went in a large measure to education. Yet, apart from all this which must be said against Henry's unjust and wasteful methods, his dissolution of the monasteries is justified by the experience of other European countries, all of whom, sooner or later, have been compelled to do the same. In Italy and Spain, where Protestantism has been virtually non-existent; in France, where Louis XIV. drove out thousands of Huguenots, and the pastor François Rochette was condemned and hanged in 1761 for exercising his pastoral office; in Austria, where

the small minority of Protestants was either driven into exile or submitted to the same leaden, crushing tyranny which England exercised over the Irish Catholics; in all these countries there has been a wholesale dissolution and disendowment.

The Tudor monasteries were probably in much the same state as that Oxford which Gibbon describes in his autobiography: and, if the universities of Gibbon's day had been entrenched behind all sorts of extra-legal privileges; if the students had been as numerous as the Tudor Religious were; and if they had successfully resisted, for at least three centuries, all serious efforts for reform, then we can hardly doubt that they also would have been disestablished and disendowed before now. The dissolution was one of many causes for a rising in Lincolnshire, and for the "Pilgrimage of Grace," in the north, where the people were poorest and least educated, and the monasteries would most be missed. Henry here showed himself a perfidious negotiator and took a very cruel vengeance; but his cause had been supported by many of the higher nobility; and he had no difficulty in getting the shire levies of the south to march against the northern rebels (1536).

Edward VI.—Under Edward VI. religious changes came far more rapidly. Henry VIII. had ended by not only permitting but enjoining the popular study of the vernacular Bible (1536–38) and, though the permission was limited in 1543 to the higher classes of society, yet even this implied a freedom of private judgment quite incompatible with mediaeval tradition, and gave an enormous, if not intentional, impetus to Protestantism. Politics, however, played almost more part in the Reformation under Edward VI. than under his father. Reformers were dominant on the council of regency which Henry had appointed; Edward's two tutors, Cheke and Cox, had both been reformers. Under the protector Somerset the chantries were suppressed and confiscated; many of them had also been scholastic foundations in a small way; and thus, though mediaeval England had never possessed an educational system in the modern sense, Edward VI. did far more harm to the schools than he atoned for by a few foundations of his own (1545).

Then, in 1548, came deliberate iconoclasm. The party which looked upon images as a hindrance to true religion was stronger now than those who found them edifying, and much regrettable violence was exercised: yet, when we take a wide view, we find that the orthodox Catholic Montalembert is right in pointing out that a larger proportion of mediaeval Gothic architecture has survived in England than in France. Edward VI. introduced an English liturgy and a Protestant confession of faith in 42 articles (since reduced to 39); and he permitted marriage to the clergy.

A Return to Rome.—His early death put the Catholic Mary upon the throne, while the country in general was still halting between the rival creeds. She communicated immediately with Rome; Cardinal Pole was sent as papal legate; and both houses of parliament answered affirmatively to Mary's question whether they would return to papal obedience. They next rescinded all the anti-papal legislation of Henry VIII. and Edward VI., and revived the statutes against heresy. Mary was now free for all violent measures.

She had promised, and perhaps intended, leniency; but here was a death-struggle between two incompatible ideals, and, in an age when scarcely anybody believed in toleration, Mary had only one choice. She executed 210 Protestants in her last three years; and, at her death, this rate was rather rising than falling. This was fatal; her very first victim, John Rogers, had been so heartily cheered by the London crowd "that he seemed to be going to his marriage," so wrote the French ambassador to his master. This sympathy, strong from the first, grew in proportion as the queen's desperate efforts intensified. Moreover, a new generation was growing up which was far more widely educated than its ancestors; and this was especially noteworthy with the women.

Elizabeth.—The country welcomed Elizabeth; and, though she was not tolerant in the modern sense, she and her ministers carried through one of the most successful compromises in history, the "Reformation settlement." Elizabeth herself would possibly have preferred a moderate form of non-papal Catholicism, though one of her earliest acts was very significant; she forbade the bishop who said mass in her presence to elevate the Host, and went out of the chapel when he disobeyed. Many of her subjects were convinced and determined Catholics. But she recognized that Protestantism had come to stay; and she so managed that it should have far more freedom than in any Catholic land, while the Catholics, on the other hand, had as much liberty as the Protestant nonconformists.

Death was the legal penalty for obstinate refusal to take the oath of royal supremacy; but in fact no Catholic who refrained from political plots needed to fear more than a shilling fine for each refusal to attend Sunday service, until after the pope had excommunicated her and decreed her deposition. Scarcely one-fiftieth of the Marian clergy were deprived of their livings for refusing the oath. Therefore the nation settled down rapidly; and the result was a more rapid national advance in learning, in literature and in commerce than at any period since the Conquest. One set of figures may be quoted as typical of the rest. The religious quarrels told very heavily upon the universities. The number of degrees fell sadly at Oxford under Henry VIII., and rose again under Mary to the mediaeval average; at Cambridge, however, they fell under Mary. From 1555 to 1558 they averaged only 28 a year; but in 1570 they had risen to 170, and in 1583 to 277, or three times the mediaeval average.

Scotland and Ireland.—The Scottish Reformation went on side by side with the English; each assisted the other. John Knox and Elizabeth were far from complete agreement; but they had sufficient sense and self-control to work together. This religious Concordat went far to obliterate ancient enmities; "Knox included in his liturgy a prayer that there might nevermore be war between Scotland and England; and that prayer has been fulfilled" (F. W. Maitland in *Camb. Mod. Hist.*, vol. II.). In 1560 the Scottish parliament did what the English had done a year before; mass and papal authority were formally rejected. Knox's *Book of Discipline*, founded mainly on Calvin's *Institution* and on the organization already adopted by French Protestantism, fixed Scotland in "presbyterianism."

The democratic character of the Scottish Reformation, and Knox's own zeal for education, go far to explain the subsequent love of learning and the high level of general education in Scotland; though the greed of the barons frustrated the hope of endowing a whole system of schools and colleges from confiscated Church property.

England's treatment of Ireland is a black page in Reformation history. The country was conquered, and the conquerors dealt with it after the brutal fashion of that time. Few Catholics lost their lives for religion pure and simple, as apart from political revolts; but a series of unjust penal statutes were enacted, and these, although seldom enforced in their full theoretical strictness, were relaxed far too slowly in the face of advancing civilization; therefore, instead of weakening, they have only strengthened the attachment of the Irish to their religion.

GENERAL RESULTS

It has sometimes been argued that the present religious equilibrium, or something better, might have been obtained without revolution. But this contention seems scarcely reconcilable either with previous or with subsequent history.

We have seen how long this revolution had been brewing. It would be difficult to find any institution which has been so severely criticized by so many of its most devoted adherents, through so many centuries, as the mediaeval Church. At the very beginning of the 12th century, St. Bernard had emphasized weaknesses which, if not remedied, must necessarily bring disaster; yet orthodox churchmen of 1500 frequently quote St. Bernard's actual words as exactly applicable to the Church of their own day. Some scandals had been abated; but others were even more rampant. Such improvements as had taken place were mainly due to pressure from the laity; and friction between clergy and their flocks seemed increasing rather than decreasing.

Subsequent history, again, seems to point even more decisively in this same direction. We have seen that the real question at issue was that of private judgment. Nearly all reformers had

two fundamental points in common with the orthodox; they wanted to save souls and they believed in the inerrancy of the Bible. But on one fundamental point they differed; is the Bible to be interpreted by the individual for his own soul's sake, or by the Church for the individual's soul's sake? The reformers acted on the former principle; and this opened the floodgates for the rest; so, although the full claim of private judgment was not the basis on which the reformers consciously took their stand, yet it was implicit in their original theories and in their original actions.

Private Judgment.—Between authority and private judgment, no agreement seems possible except the agreement to differ; yet even that was essentially impossible under the mediaeval régime. To differ publicly from any solemn pronouncement of the Church was a crime; obstinately to differ was a capital crime. Therefore no orthodox mediaeval churchman could grant to others the right of nonconformity, or could really escape from the responsibility (however much he might personally shrink from it) of denouncing and punishing all dissenters. Yet, by 1500 at least, it was becoming quite obvious that considerable numbers of Christians were trusting more to private judgment, confessedly or implicity, than to the traditional teaching of their priests.

The Inquisition had driven the nonconformists underground for nearly three centuries, very much as early Christianity had been driven underground for nearly three centuries by imperial persecution; but it was now emerging with irresistible force. The pope could not now do what Constantine had done in 324, reversing at a single stroke the policy of his predecessors. To Constantine, this religious question had been only one of many debatable issues, and he may even have looked upon it as one of the least important of his political problems; therefore, a reversal at that point need not in the least imply reversal of the whole imperial machine. To the pope, on the other hand, this question of private judgment was absolutely fundamental.

Moreover, even the strongest of popes was always far more at the mercy of his predecessors' traditional policy, of his court and of his officials, than a strong emperor. The pope had no means of coming to terms with Protestantism but by accepting the basic tenet of Protestantism; the Protestants, again, could have come to terms only by abandoning a tenet which, implicitly at least, was absolutely necessary to their position. And the fact that, after a century of strife, Christendom was, and has since remained, pretty equally divided between these two irreconcilable principles, would seem to prove that no human ingenuity could have kept the parties permanently within one single fold.

And, indeed, this division of parties seems to have worked more than any other factor towards that tolerance which is one of the greatest gains of modern civilization. The general mass of European society had improved greatly, in many important respects, between 1100 and 1500; but in this one matter of toleration there had been painful and continual retrogression. The Reformers, again, at their earliest stage, were compelled to plead for impunity; but, once in power, they proved as untrue to this principle as the Christian Church had proved when the emperors raised it from a persecuted minority to a persecuting majority.

Mutual Toleration.—Lord Acton, in one of his most plain-spoken essays, has insisted on the wickedness of this *volte-face*, and has pointed out that the innovators Luther and Calvin lacked that palliation which may be pleaded for persecutors who had persecuted in defence of tradition. But, whether we agree or disagree with him in condemning the individual persecuting Protestant more severely than the individual Catholic, the fact remains that the principle of private judgment is logically inseparable from the principle of toleration, and that no institution can survive, in the face of a powerful enemy, if it acts in public and systematic and continual violation of its own fundamental principle. There is a painful truth in the contention that both sides have learned toleration only under outside pressure; yet that pressure itself has resulted from the assertion of a principle irreconcilable with mediaeval theory and practice.

Private judgment brought half of Europe into conflict with the traditions of centuries; the resultant wars were indecisive; it became evident that neither side could exterminate the other; thenceforward both were obliged to seek some way of living together in the same world. The one party has never granted the individual's right to interpret Scripture otherwise than it was interpreted by the mediaeval hierarchy. Even Protestantism, for many generations, did not advance from the claim for individual interpretation of the Bible to the wider modern claim of rejecting, when necessary, some things that are plainly written in the Bible. But Catholics and Protestants and men of many other creeds live together nowadays in far less discord than that which often reigned in the middle ages among professing Catholics.

The Reformation thus becomes one of the most remarkable episodes in world-history, whether we regard it in bulk or in detail. It is rich in striking incidents and in display of human character, both on the Catholic and on the Protestant side; we may find here the loftiest heroism and the lowest depths of turpitude. It exemplifies all the problems of daily life, magnified in proportion to the greatness of the issues here involved. And from the heat of this conflict between two irreconcilable ideals one principle has slowly emerged, theoretically repudiated by one side and too often violated by the other in practice, yet finally victorious through the mere force of circumstances; the principle of religious toleration. The experience of centuries has now suggested that the main differences which separate many minds from the teaching of the mediaeval Church are rooted in human nature itself; and that, however near the two parties may draw to each other in the distant future, no such *modus vivendi* was possible in 1517.

REFORMATORY SCHOOL, an institution for the vocational training of juvenile offenders. In Great Britain this means offenders over 12 and under 16 years of age, who have been convicted of offences which, in the case of adults, would be punishable by penal servitude or imprisonment. The period of committal to a reformatory school is for not less than three years and not more than five years, and not beyond the age of 19. The schools are supported in the main from public funds, are regulated by the Children Act, 1908, and are supervised by the home secretary. The departmental committee on young offenders recommended, in March 1927, the substitution of 17 for 16 as the upper limit of age at the time of committal to a reformatory school and the abolition of the distinction between these schools and industrial schools (*q.v.*). *See* also BORSTAL SYSTEM. (X.)

THE UNITED STATES

The reformatory system of the United States, as distinguished from the penitentiary or prison system, may be considered under two heads: (*a*) reform schools and industrial schools for youths under 16 or 18 committed for violations of the criminal law or for the want of proper guardianship, and (*b*) reformatories for adolescents between the ages of 16 or 18 and 30 convicted of criminal acts. The former is an outgrowth of the houses of refuge, which developed in the early part of the 19th century, under private and charitable organizations.

Beginning with the last quarter of the 19th century, a number of States established industrial schools or State homes for the correction and training of their delinquent youths. The reformatory for older adolescents had its birth in the United States in 1869, when the New York State legislature enacted legislation and appropriated funds to build the New York State Reformatory at Elmira. The Elmira reformatory system of academic and trade training is still regarded as the best of its kind in the United States. Almost every State has at least one reformatory. In

practically all cases the system of discipline, training and release established at Elmira has been more or less followed. The indeterminate sentence is an integral part of the American reformatory system. Beginning with 1925 there has been a decided trend towards specialized vocational training in connection with the educational work of all American reformatories. In the most progressive reformatories the academic and vocational training is being carefully guided by psychological and psychiatric work in the clinics of the institutions. This has led to marked improvement in the classification and training of prisoners. It is significant that more and more the clinical studies are being used as a basis for determining fitness for release.

The U.S. Government opened its first Federal reformatory for adolescent male offenders in March 1926, at Chillicothe, O. In 1927 the first Federal Industrial Institution for Women was opened at Alderson, W.Va. Prior to this time, Federal offenders of all types over 16 years were received at the Federal penitentiaries. The Federal Government follows the practice of boarding many of its offenders in State reformatories and county workhouses.

REFORMED CHURCHES, a name theoretically applicable to all the churches sprung from the Reformation: but historically applied to those Protestant bodies who followed Calvin, as distinguished from the Lutheran or Evangelical communities of Germany.

REFORMED CHURCH IN AMERICA, a church founded by the colonists from the Netherlands, the first settlers of New York and New Jersey. Generally known from the beginning in New Amsterdam until now as the Dutch Reformed Church, it was incorporated as the Reformed Protestant Dutch Church in 1819. This official title was changed to the Reformed Church in America in 1867. Its oldest organization is the church on Manhattan island, known as the Collegiate church of New York city, organized in 1628, the oldest Protestant church in the Middle States and probably the oldest Protestant church of settled ministry and continuous service in the United States. The first minister was Jonas Michaelius, who associated with himself Peter Minuit, director of the colony, and Jan Huygens, elders, and Sebastian Janz Krol, deacon, as the first consistory. The second church (1642) was built at Ft. Orange, now Albany; its first minister was Johannes Megapolensis, who also was missionary to the Indians. Other churches of this early time were (1654–60) Flatbush, Flatlands, Bushwick, Gravesend and Brooklyn; (1659) Kingston; (1660) Harlem; (1660) Bergen. The passing of New Netherland from Dutch to English rule in 1664 retarded Dutch colonization and increase of the churches. Growth was constant, however, as the population spread through the surrounding regions. The work of Guliam Bertholf was especially notable from 1693 to 1724 in preaching, administering the sacraments and assisting organization in New Jersey. Theodorus Jacobus Frelinghuysen, who came from Holland in 1719, gave the Church remarkable service as leader in its spiritual life and in uniting the scattered churches into a denomination.

During the middle of the 18th century the life and progress of the Church were much affected by three questions under discussion, dividing for the time the ministers and churches into two parties: whether the ministers for the Church must be educated in theology in the Netherlands, as was insisted upon up to this time, occasioning great scarcity of ministers; whether the Dutch language ought to be the exclusive language in the pulpit; whether the churches should continue under the authority, active from the beginning, of the Church in the Netherlands. The two parties were known as the coetus and the conferentie, the one favouring, the other opposing, the changes discussed. In 1764 Archibald Laidlie was installed as one of the ministers of the New York city church to preach in the English language. In 1766 a charter was secured, and in 1770 a second charter, for Queen's college, now Rutgers university at New Brunswick, N.J., with provision for a chair of divinity. In 1771 John H. Livingston, graduate of Yale and, in theology, of Utrecht, coming to the New York church as one of its ministers, proposed a Plan of Union which united the two parties and, with the consent of the Church abroad, laid the foundations for independent Church government in the United States. In the Revolutionary War at this time the ministers and people of the Church were quite wholly on the patriot side. Among the ministers especially notable in the service of the new nation was Jacob Rutsen Hardenbergh, first president of Queen's college. Dr. Livingston became the Church's first professor of theology in 1784, the divinity work at Queen's not having been established, and thus began what is now the New Brunswick seminary, the oldest theological seminary in the country.

From this time the Church's growth was not at all confined to people of the Dutch blood, or to places of early Dutch settlement. It extended somewhat westward with the moving population. The greatest increase in its numbers and strength in the mid-west, however, has been through the coming since 1847 of many Dutch people, in protest against conditions in the State Church of Holland, to establish themselves in Michigan, Wisconsin, Iowa and the Dakotas. Their two chief centres are Holland, Michigan, where they have Hope college and Western seminary, and Pella, Ia., where they have Central college. In foreign mission fields the work of the Church has been distinguished from the early part of the 19th century; pioneer work in India, China, Japan and Arabia continued as a denominational enterprise.

The Church is of the Calvinistic faith and government. It has a formal constitution, the Plan of Union (1771) being followed by adoption in 1792 of the Articles of Dort (1619) with explanatory articles, these merged into the constitution of 1833, revised in 1874 and 1916. Its doctrinal standards are the Belgic Confession, the Heidelberg Catechism and the Canons of the Synod of Dort. Its government is presbyterial with four assemblies or judicatories, the consistory (minister, elders and deacons), the classis, the particular synod and the general synod. The organization of the local Church differs from that of the Presbyterian Church in that the elders and deacons, the consistory, are the trustees. It has a very complete liturgy, the use of some of it being required, the Church being described as semi-liturgical.

The reports of 1927 show with the general synod, the particular synods of New York, New Brunswick, Albany, Chicago and Iowa, 40 classes, 741 churches, 808 ministers and 151,281 members, contributions for missions and benevolence $1,182,268, and for congregational purposes $3,905,956.

REFORMED CHURCH IN THE UNITED STATES, a German Calvinistic Church in America, commonly called the German Reformed Church. It traces its origin to Switzerland, France and Germany and especially to the great German immigration of the 17th century to Pennsylvania where the Reformed element was estimated in 1730 to be more than half the whole number of Germans in the colony. In 1709 more than 2,000 Palatines emigrated to New York with their pastor, Johann Friedrich Hager. Other early pastors (1710–40) were Rev. Samuel Guldin, Johann Philip Boehm, George Michael Weiss, Johann Heinrich Goetschius, Johann Conrad Wirtz and Johann Bartholomaeus Rieger. Michael Schlatter (1716–90), sent to America by the Synod (Dutch Reformed) of Holland, immediately convened Boehm, Weiss and Rieger in Philadelphia, and with them planned a Coetus, which first met in 1747. Many churches and pastors were independent of the Coetus, within which there were two parties. Of the Pietists of the second class, one of the leaders was Philip William Otterbein whose system of class-meetings was the basis of a secession from which grew the United Brethren in Christ (*q.v.*), organized in 1800. During the Revolutionary War the Pennsylvania members of the church were mostly attached to the American cause; but in New York and in the South there were many German Loyalists.

The Coetus actually assumed the power of ordination in 1772 and formally in 1791. In 1792 a Synodical Constitution was prepared; and in 1793 the Coetus of Pennsylvania became the Synod of the German Reformed Church in the United States. (The word "German" was dropped from the official name in 1869 by action of the General Synod.) This first Synod met in Lancaster and adopted its own constitution, thus becoming independent of Holland. Its churches numbered 178, and there were about 15,000 communicants. The strongest churches were those of Philadelphia, Lancaster and Germantown in Pennsylvania, and Frederick in Maryland. By 1825, 13 Reformed ministers were settled west of the Alleghenies. The Synod in 1819 divided itself into eight Classes. The Synod of Ohio was organized in 1824.

Franklin college was founded with much outside help, notably that of Benjamin Franklin, at Lancaster, Pa. in 1787. In 1825 the church opened a theological seminary at Carlisle, Pa. (now at Lancaster, Pa.) and later an academy which in 1836 became Marshall college at Mercersburg where the Mercersburg theology was founded. The seminary was removed in 1871 from Mercersburg to Lancaster, whither the college had gone in 1853 to form, with Franklin college, Franklin and Marshall college. The Synod of Ohio founded a theological school and Heidelberg university at Tiffin, O., in 1850. The General Synod of the church was organized in 1863 as the highest judicatory following the tercentenary celebration of the Heidelberg Catechism, the recognized doctrinal standard of the Reformed Church, published in Germany in 1563.

After a long controversy over a liturgy (connected in part with the Mercersburg movement) a Directory of Worship was adopted in 1887 and revised in 1926. The work of the Reformed Church is directed through five boards created by and responsible to the General Synod. Since 1926 the General Synod has functioned in the interim between its triennial meetings through an executive committee of 20 representative ministers and elders. In 1928 there were seven District Synods meeting annually in the fall. These include 60 classes which meet annually in the spring of the year.

The statistical reports for 1928 reported 1,744 congregations with a communicant membership of 356,093; 1,336 ministers; 39 licentiates; 312 students for the ministry; 347,256 Sunday-school scholars; total contributions for congregational purposes $5,574,547; $1,586,974 for benevolence, and church property and parsonages valued at $48,255,581.

REFORMED EPISCOPAL CHURCH, a Protestant community in the United States of America, dating from December 1873. The influence of the Tractarian movement began to be felt at an early date in the Episcopal Church of the United States, and the ordination of Arthur Carey in New York, July 1843, a clergyman who denied that there was any difference in points of faith between the Anglican and the Roman Churches and considered the Reformation an unjustifiable act, brought into relief the antagonism between the evangelical Protestant clergy and those who sympathized with the position of Carey. The struggle went on for a generation and with increasing bitterness. The climax was reached when George D. Cummins (1822–1876), assistant bishop of Kentucky, was angrily attacked for officiating at the united communion service held at the meeting of the Sixth General Conference of the Evangelical Alliance in New York, October 1873. This prelate resigned his charge in the Episcopal Church on November 11th, and a month later, with seven other clergymen and a score of laymen, constituted the Reformed Episcopal Church, and consecrated Charles E. Cheney (b. 1836), rector of Christ Church, Chicago, to be bishop.

The Church recognizes no "orders" of ministry; the Episcopate is an office, not an order, the bishop being the chief presbyter, *primus inter pares*. *See* also ENGLAND, CHURCH OF.

REFORM MOVEMENT, the name given in history to that movement towards parliamentary electoral reform, active in England between 1769 and 1832, and in France between 1832 and 1848. Different as the two movements were in character, time (the principal phase of the English struggle was over in 1832, when the movement in France was, strictly, only beginning) and result (the ultimate desideratum of manhood suffrage was achieved in France in 1848 and in England only in 1918), the march of events in either country had a profound effect upon the movement in the other. The following article sketches the course of the movement in the two countries. (X.)

THE MOVEMENT IN ENGLAND

The ultimate, if long delayed, success of "reform," embodied in the great act of 1832 was due to an unanalysable blend of political theory and the logic of concrete fact. The political, social and economic structure of Great Britain had, in short, been revolutionized between 1780 and 1830 before the revolution was expressed in a decisive formative statute. The act of 1832 did not so much impose the new system of an ardent minority on an unprepared country as it translated into the organization of self-government the appropriate machinery for achieving what a majority had already accepted as inevitable.

The System in 1714.—The system of representation existing in 1714 was, like every other major organ of the national life, the deposit of a prolonged historic development of at least eight centuries. The House of Commons in 1714 consisted of 558 members, of whom 513 represented England and Wales and 45 represented Scotland. Ireland (with 100 members) was not included until the Act of Union of 1800, which abolished the separate Irish legislature. The Scottish representation had only been introduced in 1707 by the Act of Union. Of the 513 English representatives 94 represented counties, 415 boroughs, and four the two universities of Oxford and Cambridge; 30 members represented Scottish counties and 15 Scottish boroughs. The English franchises for the counties, and the boroughs differed fundamentally. The county franchise, with trifling exceptions, was based on a 40s. freehold, assessed to the land tax. The borough franchise was amazingly varied and defied reduction to a single principle. Four groups can broadly be distinguished: (i.) The "Scot and lot" and "pot walloper" boroughs, where the voters, roughly, were residents rated to Church and poor rate; (ii.) the boroughs where every freeman, *i.e.*, enjoying the freedom of the borough, had a vote; (iii.) the burgage-boroughs with the franchise attaching to a certain holding or burgage, and (iv.) the corporation-boroughs, where a close corporation was the privileged electoral organ.

The county franchise dated back to 1430. The borough franchise was the haphazard result of five centuries of piecemeal development. The electoral map of 1714 emphasized the enormous preponderance of voting power in the borough representatives. The distribution of the boroughs roughly represented the distribution of population at the end of the 16th century. But by 1650 this distribution had altered, and since then had been altering rapidly, even before the radical redistribution and growth caused by the "Industrial Revolution" (*q.v.*). The "Reform of Parliament" embodied in "The Instrument of Government" of the Cromwellian period (1654), demonstrated very clearly by its redistribution the admitted hiatus between the existing system and the actual facts. The elaborate analyses made by the "Reformers" of the 18th century revealed these bewildering anomalies. Apart from the contradictions of the borough franchise, which allowed a vote in one borough that was denied in another, custom degenerating into caprice, or avowed manipulation, the distribution of seats resulted in the most astonishing paradoxes. Cornwall, for example, paying 16 out of 513 parts of the land-tax, returned 42 members (two county, 40 borough members); Lancashire, paying ten times as much, returned 14 (two county and 12 borough members). The City of London returned four, as did, also, the united boroughs of Weymouth and Melcombe Regis, with neither landed nor economic interests. In Yorkshire, York city and 13 boroughs, with a total of 7,000 voters, returned 28, while the county, with a total of 16,000 voters, returned two members.

The disabilities imposed by law severely restricted both the electors and the elected. Apart from women, children, lunatics, paupers or convicted criminals, the Nonconformists, the Roman

Catholics, the Quakers, the Jews and agnostics could neither vote nor be elected. In the counties neither leaseholders nor copyholders, however wealthy, could vote. Prosperous cities such as Birmingham or Manchester, which had come into existence since 1600, had no representation, while Old Sarum with seven, or Dunwich, half under the sea, with 14 voters, returned respectively two members apiece. Even in 1714 it was abundantly clear that members of parliament did not represent their constituencies, and that the constituencies still more did not represent the nation. It was estimated in 1793 that, with a population of some eight and a half millions, 257 members (*i.e.*, a majority of the House of Commons) were returned by 11,075 electors; that in 51 constituencies there were less than 50 voters, and that 130 boroughs had less than 300 electors apiece; and that whereas 92 county members were returned by 130,000 voters, 84,000 electors in the boroughs had 421 representatives. "The rotten boroughs," *i.e.*, those which were completely under the control of the Crown or a patron, were admittedly the most indefensible parts of this parody of principles and facts.

The Society of the Friends of the People undertook, in 1793, to prove that the lords of the Treasury, 71 peers and 82 commoners could together nominate 306 out of 558 members, *i.e.*, make a decisive majority. The influence of the Crown, *i.e.*, of the Government—through the patronage of the navy, army, Church, judiciary, civil and colonial services—was enormous, and secured the steady voting support in the Commons without which no administration considered itself safe or even possible. In 1770 there were 192 place-holders in the Commons. "Vested interests" in the whole system, indeed, were so strong and deeply-rooted that nothing short of a complete organic change in the social and economic structure could compel a House of Commons to accept "reform" which meant the extirpation of a half of those who sat in it, with the lucrative possibilities that membership offered. It follows from this brief summary that the would-be "reformer" of the 18th century, with so large and easy a target to attack, but which covered such a variety of interests, had really to prove that the "system" resulted in bad government, and that in the major issues of the national life the welfare of the unrepresented was more important than the welfare of the minority and was being continually sacrificed to it. Before the political theory of Locke, Blackstone and Burke could be dissolved a new political theory had to be created and absorbed. The Reform movement had by 1830 produced such a new theory, with a re-interpretation both of the ends and methods of popular government and civil society under a limited monarchy—but it was not until 1790 when Whiggism had been dissolved once and for all by the corrosive acids of the Industrial and French Revolutions that the school of Godwin, Priestley and Price, above all of Adam Smith and Bentham, had captured the best minds alike of the old gentry and the new individualists. In 1832 a true revolution was accomplished with less bloodshed and disturbance than "the glorious revolution" of 1688, and as in 1688 so in 1832, the monarchy entered on a new lease of life, influence and prestige.

The First Phase (1714–65).—In the Walpole and Bolingbroke era (1714–40) "reform" was the cry of the broken and discredited Tories or the schismatic Whigs, who denounced the corruption by which they asserted Walpole maintained his power, or who demanded the repeal of the Septennial Act and a return of the Triennial Act, or even to the annual parliaments of a "golden middle-age." The agitation, which had no support outside Westminster, had no effect on the general acquiescence in parliaments with a legal duration of seven years, and resulted only in a very limited Place bill, disfranchising a few hundreds of place-men. The elder Pitt gave a new life and a new power to the Reform movement, due to his prestige, his disinterestedness, the splendour of his achievements, and his criticism of effete or flabby government. But Pitt was neither a consistent political thinker nor a practical and constructive administrator, capable of creating and leading a party with a coherent and thought-out programme of internal reform. He accepted the Whig view that "representation was not of persons but of property," and that "the share of national burdens (*i.e.*, taxation of *property*) should decide the weight it ought to have in the political balance." He accepted "the rotten boroughs" (for one of which he had sat) as "the natural infirmity of the Constitution." "Amputation might be death." Pitt's sole remedy for "the corruption of the people and the ambition of the Crown" was to add a third member to the county representation, "the purest part of the system," and to revert to triennial parliaments. Neither of these remedies was seriously pressed, though they became a traditional formula for the Chathamite and Rockingham Whigs.

Cartwright, 1763–80.—John Wilkes, demagogue and the popular hero of the struggle against general warrants, for the rights of the electors in the Middlesex election and for the right to report debates in parliament, with John Cartwright, the brother of the inventor of the power-loom, were, in 1776, the joint but independent "fathers" of the real Reform movement, *i.e.*, a demand not merely to eliminate the rotten elements, but by an extension of the franchise and a redistribution of seats to secure "a just and equal representation of the people." Wilkes and Cartwright pinned reform down to these points—disfranchisement, enfranchisement and redistribution—on the basis of two democratic principles, that government was for the good of the governed and that rich and poor alike had equal rights and an equal interest in determining laws and government affecting their lives, fortunes and happiness. The Reform Act of 1832 was thus foreshadowed in embryo in 1776, the year of the Declaration of American Independence, of Adam Smith's *Wealth of Nations*, and Bentham's *Fragment on Government*. Cartwright, also, by founding *The Society of the Supporters of the Bill of Rights* was the parent of a new political method, the organized league for propaganda, education and consolidation of a group with a defined and agreed programme. Radicalism, in short, as a theory of political life and a constructive political machine, was born in 1776. Cartwright's society was the fruitful mother of many leagues, societies and federations down to the Free Trade League of 1837, the "Birmingham Caucus" of 1878, and the party organizations of to-day.

The Whigs and Economic Reform.—The Whigs, under the influence of Dowdeswell and of Burke, would have none of either Wilkes' and Cartwright's principles, or of "demagogic" methods. The genius of Burke, reverencing the Constitution as almost a Divine gift to a chosen people, dreading organic change as the betrayal of a mighty heritage, and already, in 1780, scenting in the political theory of the American rebels and of the English Radicals the Jacobinical poison which the French Revolution was to let loose, saw in "economic reform" the supreme remedy for purging a sound organism afflicted by a temporary but paralysing disease in the corrupting influence of the Crown. The Yorkshire Association and the famous Yorkshire Petition of 1780 were methods borrowed from the Radicals, but "the economic reform" for which they pressed kept clear of the Radical demand for organic reconstruction of the representative system. Burke and the Rockingham Whigs succeeded in disfranchising contractors and revenue officers, in abolishing sinecures and in reducing places and a swollen pension list, but in accomplishing this valuable result they had shot their bolt. They had not attempted to deal either with the legal disabilities which excluded whole classes from representation, or with the rotten boroughs which were far more demoralizing and far-reaching in their control of parliament than the "corrupt influence" of the Crown.

The Younger Pitt (1780–1785).—The mantle of Chatham fell, and the hopes of Radicalism concentrated on Chatham's son, the younger Pitt, who, in 1781, moved for "a Committee to enquire into the Present State of the Representation" and was defeated only by 20 votes—the best division the Reformers had between 1780 and 1831. As prime minister, in 1785, Pitt endeavoured to introduce a Reform bill, his intention being to disfranchise 36 rotten boroughs, establish a fund of £1,000,000 for compensating the owners of borough "property," and assign the 72 seats set free by the disfranchised 36 boroughs to the counties, London, Westminster and the chief unrepresented towns. "Leave to introduce" was, however, refused by a majority of 79 votes. Henceforward Pitt was lost to the Reform movement. It was his first and his

last effort as a constructive Reformer and the French Revolution shortly converted him into an obstinate antagonist to all or any change.

The Fourth Phase (1785–1807).—The movement really gained in the long run by this set-back. Had Pitt's milk-and-water proposals been carried the old system would have been given a new lease of existence. Pitt, equally with Burke, accepted the inherited past, and his acceptance of the rotten boroughs as a form of property, the disfranchisement of which required compensation, was rightly rejected as immoral and indefensible on any theory of national representation, by the Reformers of 1831. The Whigs had never really believed in reform, and it now became the monopoly of the "doctrinaire Radicals." For seven years the stars in their courses fought for Radicalism. The American War had given an immense stimulus to political thinking and a new school of political philosophy came into existence; the Industrial Revolution was steadily sapping the bases of 18th century society and of the economic fabric. In 1788 the centenary of 1688 was celebrated by the ardent Radicals and the young minds of the country outside politics. In 1789 the outbreak of the French Revolution galvanized all these currents into enthusiastic activity, and The London Revolution Society—the leading organization of the Reformers, of which Price and Godwin were vigorous members—entered into direct connection with the National Assembly in France and the Constitutional Revolutionists in Paris.

Fox, who hailed the French Revolution with joy, professed to be a Reformer, but he was in reality too deeply saturated with the old Whiggism to accept with conviction the new Radicalism. The real leaders in parliament were the young Charles Grey (the Earl Grey who carried the Reform Act in 1832) and Erskine. But all the ardent aspirations of 1789–91 were doomed to disastrous extinction, for which four main causes were responsible. First, the September massacres, the execution of Louis XVI. and Marie Antoinette, and the Reign of Terror not only paralyzed the moderate Reformers with a chill of disillusionment, but sent a series of waves of panic through Great Britain. Reform was promptly identified with revolution on the French model. Secondly, once Great Britain was at war with France (1793), reform was regarded as sedition and treason. Even the mildest critic of existing institutions was denounced as a Jacobin and a traitor. Thirdly, the opposition to reform found in Burke a thinker of genius whose "Reflections on the French Revolution" became the Bible, not only of Toryism, but of three-fourths of thinking or unthinking England. To Burke the new democratic philosophy of Price, Goodwin and Paine, even of Bentham and Mackintosh, was anathema, and the "Rights of Man" were exposed as the pseudo-scientific basis of a creed which would logically end in the downfall of the monarchy, a Jacobin Reign of Terror and a military dictatorship on the French model. The extremists on the Left of the Reform movement, with the bravado that extremists enjoy, were powerful allies of reaction. For 15 years Great Britain lived in the hurricane of a European convulsion, and Wyndham's phrases as to the folly "of repairing your house in the hurricane season," for all its shallowness, correctly summed up the mood of three-fourths of Great Britain, shown in the "loyalist" riots at Birmingham, Manchester and other industrial centres. Fourthly, the irreparable breach between Burke and Fox not only split the parliamentary opposition but drove one-half of the Whigs into coalition with Pitt and the Tory Party.

The war at first was popular; prosecutions for sedition followed, and the judiciary, especially in Scotland, where a great awakening of political activity had followed the French Revolution, were ready to strain the law of treason and to lay it down from the Bench that all criticism of existing institutions was calculated to bring the Government into contempt, and was, therefore, seditious treason. The proposal to hold at Edinburgh a British convention for the discussion of reform whetted the panic of the Government and the convention was dissolved. The trials and condemnation of "the Scottish martyrs," such as Tytler, Stewart, Callender, Muir, Palmer, Margarot, Gerrald, Watt and Downie, and, in England, of Frend, Frost, Eaton and Winterbotham, make a soiled page in the history of British law. Thanks to Erskine's splendid advocacy, the acquittal of Hardy and Horne Tooke brought some sanity into the supercharged atmosphere of indiscriminate terror and proscription. But until 1799 liberty of opinion ceased to exist in Great Britain, and in this valley of black shadows the numerous political societies, the chief of which were *The London Corresponding Society* and the *Society of United Scotsmen*, withered at the roots and were easily and finally suppressed by governmental action (1794–98). There would have been general and resentful astonishment could the memorial to "the Scottish Martyrs," on the Calton hill, at Edinburgh, erected by public subscription have been foreseen in 1800. Muir's "blasphemous" prediction that "the cause would ultimately prevail" was accepted as a platitude by a reformed and grateful Great Britain in 1844.

It "prevailed" for three reasons. First, the existing system of parliamentary representation provided its own condemnation when men could once more use their eyes, unblurred by panic and warfever. Secondly, every five years of the changes made by "the Industrial Revolution" threw up a new and unrepresented population, creating a new wealth which paid three-fourths of the taxes but, under the old system, was not "property" with any political rights. Thirdly, the real Reformers retained their faith, and the new and abhorred creed of "democracy" was being hammered out by powerful minds, and could be proved to have a better scientific basis for the theory of a reborn, civilized and progressive society than the philosophy of Burke. To the England of 1807 and onwards the old Whig creed of 1688 was not to be regarded as a climax and a terminus, but simply a stage in an inexhaustible development.

The Fifth Phase (1807–1815).—A new point of departure was made in 1807. The Westminster election of that year brought Sir Francis Burdett, a wealthy and ardent Reformer, into the House of Commons to be the fearless and effective champion of the new Radicalism. The indefatigable Cartwright, who lived until 1824 and saw the dawn of the new day, was ready to join with Cobbett, "orator Hunt," Bentham, the stubborn and aristocratic Whig, Coke of Holkam, the "King of Norfolk," of whose respectability and place in the great gentry there could be no doubt. Reform had, in fact, its increasing adherents alike in the peerage, the intelligentsia and "the people." It only needed now two further acquisitions—the conversion of the official Whig Opposition and a first-rate organizer. The latter was found in Francis Place, the tailor of Charing Cross, whose career and gifts make a fascinating chapter in the history of British politics. Place, if any man, was the "organizer of victory." The conversion of the Whigs, led by Grey (who had succeeded to the earldom in 1807) was accomplished in 1820, when Lord Russell definitely associated the Whig party with the cause. Russell was ably supported by Brougham, and even more effectively by the aristocratic Radical, Lambton (later Lord Durham of the "Durham report"). Cartwright, in 1823, predicted that reform would "come suddenly." He did not live to see the passing of the Nonconformist Emancipation Act in 1828, of Roman Catholic emancipation by a Tory minister in 1829, or the triumphant passage of the Reform Act of 1832, nine years after his prediction. It was, indeed, in the irony of history that the French Revolution of 1789 should have shattered "the cause," and that a second revolution in France in 1830 should convert Great Britain to enthusiastic support of the Whig Reform bill of 1831.

BIBLIOGRAPHY.—The reform movement is treated in all the general histories and text books, notably by W. E. H. Lecky, *A History of England in the Eighteenth century* (1878–90; new ed., 7 vols., 1892). The best special books are: E. and A. G. Porritt, *The Unreformed House of Commons. Parliamentary Representation before 1832*, 2 vols. (1903); G. S. Veitch, *The Genesis of Parliamentary Reform* (1913); J. R. M. Butler, *The Passing of the Great Reform Bill* (1914). *See* also T. E. May, Baron Farnborough, *The Constitutional History of England since the Accession of George the Third; 1760–1860*, 2 vols. (1861; edit. and cont. to 1911 by F. Holland, 3 vols., 1912); W. R. Anson, *The Law and Custom of the Constitution*, vol. i., "Parliament" (1886–92; 5th ed. by M. L. Gwyer, 1922). Of the numerous biographies, *see* particularly: G. Wallas, *The Life of Francis Place* (1918); and G. M. Trevelyan, *Lord Grey of the Reform Bill: being the life of Charles, second Earl Grey* (1920). (C. G. Ro.)

THE MOVEMENT IN FRANCE

If the political history of France be compared with that of England, it will be seen that the political system of both countries underwent similar changes, and arrived at approximately the same result—the main features of which were a responsible ministry and popular suffrage.

The political organization which was created both in France and in England was based on three essential elements: (1) an elected assembly capable of imposing an effective limitation on the power of the monarch; (2) a council of ministers subject to the control of the assembly; (3) an electorate capable of maintaining the control of the nation over the assembly. Three things were thus necessary in order to establish responsible government: the arbitrary power of the king must be restricted by an assembly independent of the court; the assembly must obtain effective control of the Government by transforming the king's ministers into agents for carrying out the will of the assembly; and the electoral system must be such as to ensure that the members of the assembly were representative of the will of the people.

In France the power of the king was so great that the people, who possessed no institutions through which they could exercise their action, were unable to impose any limitation on his authority. At a period when Great Britain already had a government responsible to an elected parliament, France had no political assembly, no franchise, and no check on the arbitrary power of ministers. The latter were simply the instruments through which the king exercised his personal authority.

It was impossible to modify this system, as had been done in England, by introducing successive improvements in the method of government, because there was no machinery in France through which control could be exercised. The change was made, without transition, by revolution; the old system of government was destroyed, and a new one had to be improvised. In devising a new system of government in this way it was of course necessary to proceed according to a general plan and to apply uniform rules of a legal and abstract character, whereas the British constitution was rather in the nature of a body of customs built up by a series of historical precedents. The difference in the method followed in the two countries has generally been attributed to a difference of national temperament, the Englishman being more phlegmatic, conservative and practical, and the Frenchman more passionate, revolutionary and fond of abstract ideas. It may however be more naturally explained by the different conditions under which the transformation of the political system was effected in the two countries. England already possessed an elected parliament which tended by gradual development to establish its control over the ministry; all that the English had to do was to reform their archaic electoral system. The French nation had to improvise an entire political system, and could only do so by the application of general rules.

The Revolution.—The French Revolution was initiated by the action of the royal Government itself in calling a meeting of the States General for the purpose of voting money. The meeting of the States General was not however, like the English parliament, an institution with the force of tradition behind it. The meeting called in 1789 under the old name of the States General was in reality a new assembly, summoned by a procedure created expressly for it.

Thus the question of the electoral system, which was the last to be settled in England, was in France the one which arose earliest. The system adopted was uniform for the whole country, and thus more logical than that of England. Voting was by secret ballot and by absolute majority. As the Government had extended the right to vote to all tax-payers, including the very numerous peasant class, the election of the deputies of the Third Estate was carried out by indirect suffrage. A system of indirect suffrage of two degrees, with a secret ballot and absolute majority, was applied to all elections of legislative bodies throughout the Revolution period.

The assembly, converted into a "National Assembly," declared that it would not separate until it had given France a Constitution; the royal power was thus limited by an elected body representing the nation as a whole. After the fall of Louis XVI. it became necessary to vest all powers in a single body, which was given the name of the Convention, a term borrowed from the United States. When the Convention desired to restore a regular political order conforming to the doctrine of the separation of powers, all that it could do was to replace the king by an executive Directory.

The third question, that of the qualifications and functions of ministers, had been settled under the pressure of practical necessities in 1789, when it had had to be decided whether ministers might also be members of the Assembly. The Constituent Assembly had been apprehensive of the influence which ministers might exercise over the legislative body; it feared the ambition of one of its members, Mirabeau. Ministers, as members of the executive, were therefore forbidden to be at the same time members of the Legislative Assembly; and this made it impossible to establish a system of responsible government in France.

The Restoration.—The institutions created by the Revolution were abolished by Napoleon, who reduced assemblies, elections and ministers to the position of instruments through which the absolute authority of the emperor was exercised. At the Restoration, however, a fresh attempt was made to create an organized political system. Louis XVIII. accepted the limitation of the royal power by a constitution and its control by an assembly. The three questions which had had to be considered in 1789 thus arose again in 1814; this time they were settled on lines directly copied from Great Britain.

Under the imperial regime there had been two chambers; Louis XVIII. maintained them under different names. The senate became a hereditary chamber of peers; the Legislative Assembly became the chamber of deputies, and the king had power to dissolve it, as in England. The chamber adopted a number of the practices of the British parliament, such as the King's speech, the voting of the Address, and the procedure for voting on ways and means.

The method of selecting ministers was not regulated by the Charter of 1814, just as there were no formal rules on the subject in England. Ministers were responsible, but only in the case of action contrary to the constitution, when they were liable to a procedure copied from the English system of impeachment. Thus France did not yet enjoy responsible government in the sense in which the term is understood in English-speaking countries at the present day. Louis XVIII. however generally followed the practice of forming the ministry in agreement with the majority of the chamber, and when Charles X., in 1829, appointed ministers who were definitely unpopular, the majority made an official protest, the "address of the 221," in which it enunciated the theory of responsible government.

The dispute led to an insurrection in Paris, and the Revolution of 1830 was the result. The new king, Louis Philippe, formally recognized the sovereign rights of the nation, and accordingly did not contest the principle of the responsibility of ministers to the Chamber. France thus adopted the principle of the political responsibility of ministers, according to which a minister is obliged to resign as soon as he is in disagreement with the elected Chamber.

"The Reform Movement."—The electoral system in France had been a constant subject of party controversy from 1814 onwards. The practice of holding elections had been introduced as a new departure in 1789; it was not a long-standing tradition as it was in England, and it had not struck deep root in the political life of the nation. The Charter of 1814, which was hastily drafted, only contained a single provision dealing with the electoral system; no one was entitled to vote unless he paid not less than 300 francs in direct taxes. This represented a much more limited franchise than that in force in England, and the result was to deprive the elections of their popular character.

It was not until later that legislation was adopted fixing the minimum tax payment constituting the electoral qualification and the procedure for elections. The act of 1831, which was passed after the Revolution, merely lowered the electoral qualification from 300 to 200 francs. This resulted in increasing the number

of electors from 87,000 to 166,000; a maximum of 249,000 was reached in 1847.

One section of opinion in France regarded this reform as insufficient, since the large majority of citizens were still excluded from political life. Demands for the extension of the franchise were therefore put forward. At the time when in England the reform movement which had been initiated 60 years earlier was at last achieving success in the Reform Acts of 1832, agitation for the same object in France was only beginning. It is to the movement of 1832–48 that the term "reform" is applied in France.

Neither in France nor in England were the supporters of an extended franchise able to agree on the scope of the desired reform. Universal suffrage, which had been advocated in England as early as 1780, was not at first proposed in France except by a few isolated republicans. The *Société des Droits de l'Homme,* an association consisting mainly of young Parisian students and workmen, referred to universal suffrage in its manifesto of 1833 as an instrument for bringing about social revolution and improving the position of the proletariat; this attitude corresponded to that of the English Chartists.

The supporters of a less radical measure of reform put forward their demand for an extended franchise in the form of petitions to parliament, as had been done in England. The movement did not attain real political importance until 1838, when the National Guard of Paris, in which nearly the whole of the lower middle class population was enrolled, organized a petition asking that all members of the National Guard should be given the right to vote. A committee of deputies was formed to direct operations in the provinces; public manifestations were arranged, in which the National Guards marched in procession to greet the deputy with cries of "Vive la Réforme." The same cry was raised on June 14, 1840 at a review of the National Guard by Louis Philippe. The petition obtained about 240,000 signatures.

The opposition accused the Government of corrupting those deputies who were in the Government service by promises of promotion, and the electors by granting them personal favours. As a remedy for the "corruption" of deputies it demanded "parliamentary reform," *i.e.,* that civil servants should be forbidden to sit in the chamber. As a remedy for "electoral corruption" it demanded "electoral reform." These were the terms which had been employed in England in the time of George III.

Universal suffrage was at no time demanded by more than a very small minority, much less numerous than the Chartists in England. Almost its only champion in the chamber was the lawyer Ledru-Rollin, who founded a journal entitled *La Réforme* in 1843. Ledru-Rollin represented political reform as a necessary condition for social reform. *La Réforme* did not however have a circulation of more than 2,000.

The campaign for reform was carried on in the chamber principally by the party which was opposed to the dynasty. For some years the question formed the subject of debates which led to no practical result. Guizot, the virtual head of the ministry, always replied that the introduction of reform measures was inexpedient. Louis Philippe himself took part in the dispute. "There will be no reform," he said in Jan. 1848; "I will not have it. If the Chamber of Deputies votes for it, I have the Chamber of Peers to reject it. Even if the Chamber of Peers adopted it, I have my veto."

The restrictions imposed on the press by the legislation of 1835 made it difficult for the opposition to state its views in the newspapers. A means of expression was found in the organization of a series of public dinners by opposition deputies and journalists; some 70 such dinners were held in 1847 and 1848, and toasts were drunk in honour of Reform. The Government, by prohibiting a public dinner in Paris, provoked the revolt which led to the Paris insurrection of Feb. 23 and the overthrow of the monarchy. The provisional Government, composed of deputies representing the small republican minority, at once introduced universal male suffrage. Thus electoral reform, which was only begun in England after half a century of agitation, was consummated in France in a few days in its most radical form. (C. Se.)

REFRACTION. When waves of any kind travelling in one medium enter another, in which their velocity is different, their direction is, in general, changed; the rays, *i.e.,* the lines perpendicular to the wave surfaces (in isotropic media) along which the energy travels, being bent or refracted at their point of incidence on the second medium. The change in direction is such that the sine of the angle formed by the incident ray and the normal to the surface of separation bears the same ratio to the sine of the angle formed by the refracted ray and this normal, as the velocity of the waves in the first medium to their velocity in the second. This ratio, known as the refractive index, may depend on the frequency of the wave vibrations. If such be the case, each frequency in the incident disturbance gives rise to a separate refracted ray—a phenomenon known as Dispersion. (*See* Light.)

Mirage is due to the refraction of light by layers of air of gradually varying temperature and density. A similar variation, due to convection currents, is responsible for the flickering appearance seen, *e.g.,* above asphalt and sand on a hot day, and also for the twinkling of the stars. (*See* Star.) The refraction of rays of light entering the earth's atmosphere from heavenly bodies is known as Astronomical Refraction; it has the effect of making such bodies appear higher above the horizon than they really are. (*See* Astronomy, *Spherical.*)

REFRIGERATION AND ICE MANUFACTURE. Refrigeration is understood to mean the process of securing a temperature below that of the atmosphere by the use of some mechanical device. It has three main divisions: Cold storage and food preservation (packing plants, etc.), ice making and air conditioning and cooling. The extent of these applications is extending rapidly and in addition special processes requiring refrigeration —as in the chemical industries—are being developed so that refrigeration is becoming increasingly important.

THEORY OF REFRIGERATION

The most general method of securing mechanical refrigeration is to use a reversed heat engine whereby heat is absorbed at the lower temperature and is rejected at the upper temperature with a direct acting engine or an electric motor, providing the external work required to make the cycle possible. If the Carnot heat cycle (*see* Internal Combustion Engine) is used for the production of power the reversed Carnot cycle is the one employed in the refrigerating cycle. Such a reversed cycle cannot have a greater efficiency than the direct cycle.

According to the second law of thermodynamics (*q.v.*) the efficiency of the cycle is independent of the kind of working medium used, and is dependent only on the temperature limits. If it were possible to operate according to the Carnot cycle one refrigerant would be as efficient as any other but as all practical refrigerating cycles deviate from the Carnot it will be seen later that such is not the case exactly. This deviation is mainly on account of the use of a throttle valve in order to reduce the pressure of the liquid before it enters the evaporating coils instead of an expansion motor as would be required in the reversed Carnot cycle to provide the necessary adiabatic expansion.

Heat Cycles.—Heat engine cycles can be shown graphically in a number of ways. The *P–I* (Pressure-Thermal Potential) diagram, shown in fig. 1, is the simplest and most useful diagram for representing the refrigerating cycle. The value of I is given by the expression $I=U+Apv$, where U is the energy, p the pressure, v the volume, $A=1\div 778$; therefore $di=du+Apdv+Avdp$, but $dq=du+Apdv$; therefore $di=dq+Avdp$, so that for a constant pressure process $di=dq$ or $i_1-i_2={}_1Q_2$. From the last equation it is clear that in a constant pressure process the heat absorbed is equal to the difference in the value of i at the beginning and the end of the process.

The Refrigerating Cycle.—In refrigeration the volatile liquid is permitted to pass into evaporating coils under reduced pressure and there it boils, absorbing heat from the commodities to be

cooled. The liquid at the condenser pressure is indicated by the point *a* in fig. 1 and the line *ab* is the drop of pressure in the pressure reducing (the so-called expansion) valve. Such a throttling process is one of constant *I* and is shown by a vertical line on the diagram. If an expansion cylinder had been used, the dotted line ab_1 would have indicated the process and this being reversible in the thermodynamic sense, the cycle would be more

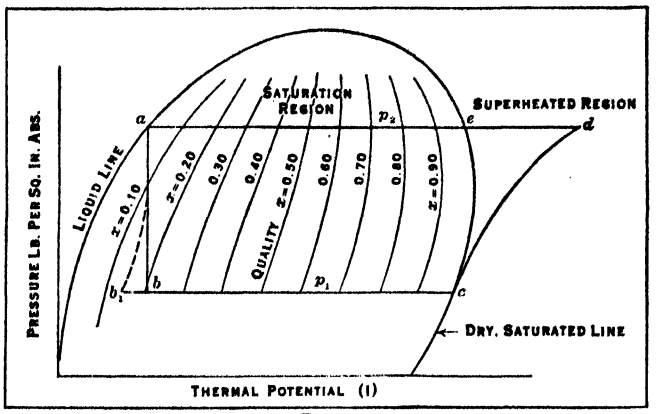

FIG. 1

efficient than the one having the expansion valve. The point *b* represents the condition of the working medium with the reduced pressure, and with the temperature corresponding to the pressure obtainable from suitable thermodynamic tables. Fig. 1 shows that the point *b* corresponds to a point having 21% vapour, or (in other words) 21% of the liquid is evaporated in cooling the liquid refrigerant from the temperature at *a* to that at *b*.

Useful refrigeration is shown by the evaporation line *bc*, during which time the heat absorbed by the refrigerant per pound is $i_c - i_b = i_c - i_a$. The point *c* represents the gas leaving the evaporator coils and entering the compressor. The compressor process is shown by the line *cd* and the work of compression per one pound of the refrigerant is given by the value of $i_d - i_c$. Finally the constant pressure line *da* represents the heat lost by the compressed gas first in the removal of the superheat *de* and then the latent heat of liquefaction *ea*. The heat absorbed by the condensing water per one pound of the refrigerant is $i_d - i_a$.

As stated, the useful refrigeration per pound of refrigerant is given by the expression $i_c - i_a$. In the United States the ton of refrigeration is defined as the absorption of 200 B.T.U. per minute. The ton of refrigeration in Great Britain is given as the absorption of one kilogram calorie per second which is larger than the United States unit by 18·8 per cent. Using the United States definition the piston displacement per ton of refrigerant per minute theoretically is

$\frac{200}{i_c - i_a} V''$ where V'' is the volume of 1 lb. of dry, saturated refrigerant at the pressure p_1.

Allowance, however must be made for the volumetric efficiency which may be as small as 50% or less under extreme conditions. This is a factor to account for the superheat in the suction gas occasioned by the absorption of heat from the cylinder walls, piston head, etc. An idea of the extent of this loss can be seen in Table I.

The preceding equation can be corrected for volumetric efficiency as follows:

$\frac{200}{i_c - i_a} \frac{V''}{E_r \times E_v}$ where E_r = the volumetric efficiency due to the effect of the cylinder walls, etc.
E_v = volumetric efficiency due to clearance.

The work done by compression, per ton of refrigeration, is

$\frac{n}{n-1} p_1 V_1 \left[1 - \left(\frac{p_2}{p_1}\right)^{\frac{n-1}{n}}\right] \frac{200}{i_c - i_a}$

where $n = 1{\cdot}28$ for ammonia and carbon dioxide, p_1 is the suction pressure in lb. per sq.ft. and V_1 is the volume of 1 lb. of dry saturated vapour at the pressure p_1.

Also referring to the figure the value $i_d - i_c$ = the work performed in the entire cycle in compressing the pound of gas. The work of compression, per ton of refrigeration, is also

$$200 \frac{i_d - i_c}{i_c - i_a} \text{ B.T.U. per minute} = 4.713 \frac{i_d - i_c}{i_c - i_a} \text{ i. hp.}$$

The formula for the work of compression and horse power should be increased by an amount $\frac{1}{E_r}$ to account for the effect of volumetric efficiency. Clearance has been found to have little effect on the *i*. hp. and is usually neglected in power calculations.

TABLE I. *Horse-power per Ton of Refrigeration (Ammonia)*

Condenser pressure lb. gauge	Suction pressure lb. gauge					
	5	10	15	20	25	30

	B	0·49	0·61	0·68	0·72	0·75
	C	0·37	0·52	0·62	0·67	0·71

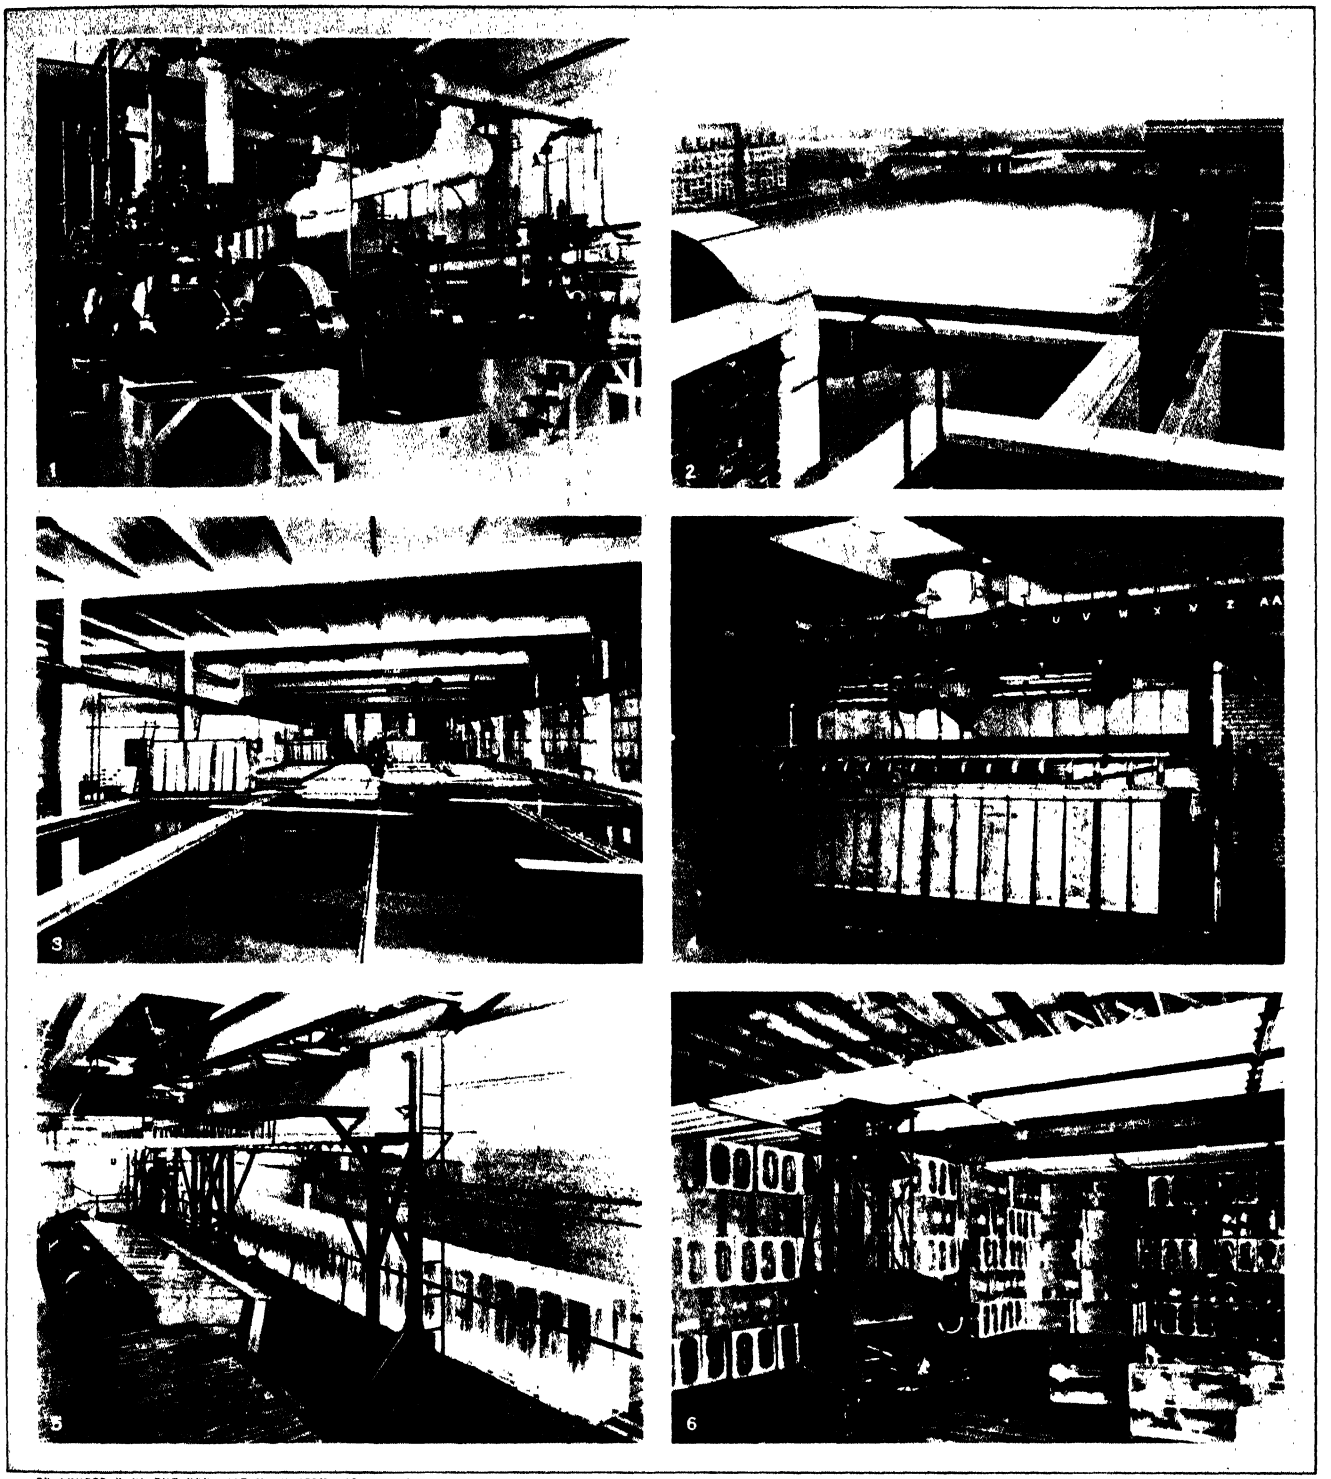
A, No clearance. B, 4% clearance. C, 6% clearance.

The water required for condensing purposes may be calculated as follows:

The heat absorbed theoretically by the condensing water per ton of refrigeration per minute is

$$\frac{200}{i_c - i_a}(i_d - i_a) = 200 \frac{i_d - i_a}{i_c - i_a}$$

and allowing for volumetric efficiency, this formula becomes



$$\frac{200}{E_r} \frac{i_d - i_a}{i_c - i_a}$$

If the water rises in temperature 10° F, then the number of gallons of condensing water will be per ton of refrigeration, per minute,

$\frac{200}{8.33 \times 10 \times E_r} \left(\frac{i_d - i_a}{i_c - i_a}\right)$ where 1 gal. weighs 8.33 lb.

REFRIGERANTS

Although the second law of thermodynamics (*q.v.*) states that equal efficiency can be obtained with all refrigerants operating between the same temperature limits, yet this is not strictly true in practice. However, the power required of the compressor per unit of refrigeration is not the only important factor in the choice of a suitable working medium, but the pressures encountered, the piston displacement per ton of refrigeration, the effect of the refrigerant on animal and vegetable life and on commodities, its dangerousness due to possible explosions and its corrosive action on the metals of the system, all have to be considered. By a system of elimination, ammonia, carbon dioxide and sulphur dioxide are the only refrigerants used to any extent. Hydrocarbons are proposed, but are not used. Ethyl and methyl chloride are used to some degree but have not come into great use, except for special purposes. Air, water vapour and mixtures of two different volatile liquids have been proposed but are not used for

BY COURTESY OF THE YORK ICE MACHINERY CORPORATION

PROCESS OF ICE MAKING

1. Ammonia compressor of the horizontal duplex type. Two compressors are coupled to a single synchronous motor between them
2. "Spray pond" for cooling water for ammonia condenser purpose. It is surrounded with louvers to conserve the supply
3. Freezing tank filled with brine. Ammonia pipes absorb heat from the brine and lower the temperature. A group of cans filled with water are placed in the tank and their contents frozen to a solid
4. Can-filling apparatus. A group of cans are conveyed to the freezing tank by means of the crane above the cans
5. Cans are emptied and the blocks of ice are transferred to storage by means of a conveyor
6. Ice storage room showing the blocks stacked by tiering machines in the foreground. Ammonia pipes in ceiling keep moderate temperature to prevent ice from melting

obvious reasons. One design of centrifugal compressor makes use of dichloroethylene with condenser sub-atmospheric pressures.

TABLE II.—*Characteristics of Various Refrigerants*
From Macintire's Handbook of Mechanical Refrigeration

Refrigerant	Thermal potential of the vapour at 5° F	Thermal potential of the liquid at 86° F	Net refrigeration per pound	Specific volume	Piston displacement theoretically per ton of refrigeration per minute	Suction pressure lb. per sq. in.	Condenser pressure lb. per sq. in.	Piston displacement, CO_2 as unity
Ammonia (NH_3)	613·3	138·9	474·4	8·15	3·44	34·3	169·2	3·82
Carbon dioxide (CO_2)	101·0	44·0	57·0	0·256	0·898	332	1,050	1·0

Ammonia.—In nearly all general refrigeration (*i.e.*, cold storage, ice making) ammonia is used as the refrigerant. Ammonia has nominal pressures, requires only a nominal piston displacement per ton of refrigeration, as shown in Table II., and is as economical in power requirements as any of the refrigerants in use. However, it does react with copper and composition if moisture is present and it is explosive with certain limited mixtures of air. Ammonia fumes in moderate amounts are extremely dangerous to animal and vegetable life. In consequence special attention has to be given to maintaining a tight system both as a safety precaution and to save the charge of the refrigerant.

Carbon Dioxide.—Carbon dioxide is almost an ideal refrigerant. It is non-explosive, inert like nitrogen in its effect on animal life and is not undesirably active chemically. However, working pressures are high, being from 900 to 1,200 lb. per sq.in. in the condenser and from 300 to 500 lb. in the evaporation coils. It has a very low critical temperature (88°), and in consequence the gas cannot be condensed in the condenser when using condenser water of 85° or more. The heat content of the liquid is large in proportion to the latent heat of vaporization and the net refrigeration per pound of carbon dioxide is small. It follows from this fact that the power required to compress carbon dioxide in the practical cycle is greater than for ammonia under identical temperature limits. Carbon dioxide is superior to ammonia for condensing water of 70° or less, and for low temperature refrigeration. Partially because it is a safe refrigerant, it is frequently used in theatre refrigeration and in marine work.

Sulphur Dioxide.—Sulphur dioxide is used to some extent in general refrigeration in Great Britain and on the Continent in capacities as large as 100 tons, but in the United States sulphur dioxide is confined mostly to the fractional tonnage compressors. In household machines it is especially successful, as the condenser pressure is less than 100 lb. per sq.in., even with the air-cooled condenser which is required in this kind of work. The gas is non-explosive, but is dangerous to animal life. It does not react with steel or copper if it is anhydrous, but acts with both if any water is present.

Methyl Chloride.—Methyl and ethyl chloride may be used to advantage as refrigerants. The main objection to their use is the difficulty in detecting leaks, a matter which in the case of the fractional tonnage compressor particularly is a very serious fault. In other respects these refrigerants have decided advantages over sulphur dioxide as they are harmless in moderate amounts in the air and are not "corrosive."

Air.—Air was one of the first refrigerants to be used successfully, being the working medium of the Bell-Coleman compressor. In the case of a perfect gas the energy is a function of the temperature only and therefore in order to get a drop of temperature an expansion cylinder must be used in place of the expansion valve. In this way a certain percentage of the work of compression can be returned to the shaft, but such a machine has been found to be inefficient and hard to keep in good operating condition.

Mixtures of several substances have been attempted with no good results. Leaks cause a variation in the relative percentage of the mixture, the result being a complete lack in uniformity in the properties of the substance.

The Compressor.—The refrigerating compressor is a reversed heat engine and is used to increase the pressure of the gas in order that liquefaction may be obtained with condensing water at or near the temperature of the atmosphere. The object of the compressor is to perform the work as efficiently as possible and to use in consequence as little power for the purpose as is practical. The gas from the evaporating coils should enter the cylinder of the compressor during the suction stroke with as little drop of pressure as is practical and there should be a minimum excess pressure developed over that due to the surface tension of the liquid in the condenser during liquefaction. Attempts have been made to reduce the amount of "wire-drawing" (*see* THERMODYNAMICS) to a minimum by the use of valves permitting a large net opening for the flow of the gas by providing large straight ports and connections to the evaporator and the condenser. As the mechanically operated suction valve is only used in a few cases and the mechanically operated discharge valve is never used it is also essential that both the suction and discharge valves should be of light weight. This requirement is even more important because of the desire in late years to increase the rotative speed from 40 to 60 r.p.m. of 20 years ago to 400, 500 and even 600 r.p.m. to be found even now in the smaller sizes. The result has been the adoption of the plate and ribbon valves, the light weight poppet valve for the discharge and the so-called balanced poppet valve in the piston of certain vertical single acting compressors.

With the increase in rotative speed has come the necessity of a positive system of lubrication, following somewhat the method employed in automotive design. The smaller single acting enclosed compressors are splash lubricated except those of high speed which have a force feed to the several bearings. The larger sizes have a filter in addition and by means of bulls-eyes there is an indication of the amount of oil going to these important bearings.

Clearance.—The amount of clearance in a refrigerating compressor is important from the point of view of the capacity of the machine but not from that of the horse-power required to perform the work of compression. Certain types of valves make it impractical to design the machine with small clearances, and the result is that little attempt is made to restrict the clearance except where this is easily accomplished. Where clearance has to be used the resultant loss of capacity may be offset readily by the addition of ½ in. or more to the cylinder bore. Recently the use of clearance pockets has become popular whereby the opening up to the cylinder of one or more clearance volumes has been permitted. These volumes may be added to the clearance at will by the opening of one or more valves on the head end of the cylinder, thereby making it possible to adjust the capacity of the compressor to the load on the machine, an ability which would not be possible with constant speed drives as is the case in oil engine, and certain electric motor connections.

Number of cylinders.—In the United States the number of cylinders connected together on the same crank shaft has seldom been more than two, although three cylinders are to be found in the case of large vertical single acting enclosed crankcase compressors which are designed for special purposes, and in some small machines. In Great Britain four cylinders are common as the capacity can be increased readily by the addition of cylinders, and this method appears to be preferred to that of the increase of the bore.

The Absorption Machine was more important about 1913 than in 1929. This refrigeration machine requires the direct application of heat instead of mechanical work in order to increase the pressure of the gas to a point where liquefaction may occur in the condenser. The heat necessary for this action may be due to the burning of gas or it may be obtained from high pressure or exhaust steam. In the United States the absorption machine is used where exhaust steam is plentifully available and also in the small fractional tonnage units.

The principle of the action of the absorption machine is that a solution of ammonia and water is used in a still or generator where heat is applied. The action of the heat is to drive out some of the gas from the solution under a pressure corresponding to the condenser pressure, and the gas is condensed, in the condenser, and passes to the evaporator in the same manner as is the case in the compressor system. However, the gas from the evaporator has to be returned as a solution, or strong aqua, to the generator. This is done by sending the weak aqua, which is at the lower part of the generator, to the absorber having cooled it previously, and there bringing it into intimate contact with the gas from the evaporator. The resulting strong aqua occupies very little volume in comparison with that of the gas from the evaporating coils, and may be pumped by means of a strong aqua pump into the generator.

The advantages of the absorption machine are the use of exhaust steam at very low cost. It is used in the United States in packing plants, oil refineries and in some hotels where a combination of the steam-driven compressor and the absorption machine works out economically at times. The absorption machine will also take a low temperature of evaporation without difficulty because the volume of the strong aqua from the absorber is not affected by the evaporator pressure in any way. However, these advantages had lost their importance by 1928 because of the economical advantage of stage compression.

The Intermittent Absorption Machine.—The absorption machine described above has one moving part, the so-called strong aqua pump. In order to eliminate all moving parts the machine may be modified in such a way that it then will operate intermittently. In the intermittent absorption machine the still or generator is also used as an absorber. During the period when heat is applied to the generator the ammonia gas is distilled off to the condenser to be condensed and finally stored in a liquid receiver. When the required amount of liquid has been accumulated the steam or gas is shut off from the generator, cooling water is turned on and the expansion valve opens. As liquid passes into the evaporating coils refrigeration is accomplished and the gas proceeds to the generator now acting as an absorber, and is kept cool by the water-cooling coils. The intermittent absorption machine has less surface than the regular absorption machine as it eliminates the absorber, the exchanger and the weak aqua cooler as well as the strong aqua pump. It cannot, however, give continuous refrigeration. The machine operates automatically.

The Platen-Munters Absorption Machine.—This is another type of machine built to eliminate the strong aqua pump (*see* fig. 2). The outstanding features are the elimination of the expansion valve by a device whereby the pressure in the system is made constant throughout the cycle and the addition of a charge of an inert gas, usually hydrogen, in the evaporating coils and the absorber. As the pressure in the absorber and the generator is the same, a force sufficient to overcome only the frictional resistance of the pipes is required. This unbalanced force is obtained by means of the difference in weights of two columns, one (the strong aqua) connected with the heating coils, and therefore of less density, and the other with the cooler and more dense weak aqua. The action of the hydrogen in the system is very interesting. The boiling temperature of the ammonia in the evaporating coils is dependent on the pressure exerted by the ammonia which in turn is determined by the proportionate amount of hydrogen present. The underlying principle is that of partial pressures by which the hydrogen is charged into the evaporating coils and the absorber in such an amount as will limit the ammonia pressure to 30 or 45 lb. per sq.in. Recently other absorbents for the gaseous refrigerants have been developed, one of which is silica gel. Such absorbers are solid materials composed of a large number of minute air cells, capable of absorbing sulphur dioxide as well as ammonia.

Fittings.—The working medium, or refrigerant, is contained in refrigeration in a closed system and is used continuously. It is dear enough to make it desirable to keep leaks down to the lowest point possible and, with ammonia, dangerous enough so that execessive leaks are to be carefully avoided. The result is that the design of the system has the prevention of even nominal leaks as a first consideration. In consequence the pipe fittings are made specially strong, and are either of dense, air furnace, cast iron or are drop forgings. The screw joint is made up with litharge and glycerine or a soldered joint is made up by tinning the screw threads. With drop forgings the fitting may be welded to the pipe, and this has been found especially advantageous in the case of carbonic systems.

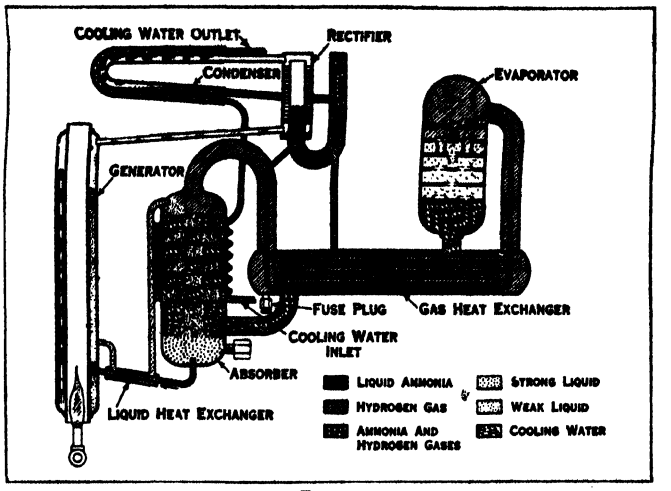

FIG. 2

The piping may be either steel or wrought iron and usually of standard weight. The pipe is usually lap-welded in sizes 2 in. or over and butt welded in smaller sizes.

Condensers.—Design has undergone considerable advancement since 1918. At first safety dictated the use of pipe condensers, arranged in stands of 30 or more pipes high and with pipes 20 ft. long, but the height of the stands has been gradually decreased until now the usual number is 12 pipes. In these pipe condensers the gas from the compressor enters at one end of the condenser, and the refrigerant is condensed during its passage through the 200 or more feet of pipe composing the condenser. Attempts to achieve counter-flow of the ammonia and the condensing water and more control in the velocity of the water have resulted in the following types of condensers: the submerged, the common atmospheric, the double pipe and the flooded designs. The more recent designs are the shell and tube single pass and the shell and tube multi-pass condensers. In the multi-pass type the water fills the tube whereas in the vertical shell and tube condenser the water is made to flow as a film on the inside of the tubes.

Research on heat transfer in ammonia condensers has developed so that there is no advantage in the counter-flow principle, whereas it is highly desirable to remove the liquid condensate as quickly as possible from the condensing surfaces. It has been found impossible to subcool the liquid unless the liquid is free of its own vapour and so the elaborate attempts to achieve the counter-flow arrangement are not worth the trouble. On the other hand the ordinary condenser has 50% of all liquefaction occurring in a small portion of the condenser where the condensing water enters the condenser. This part of the condenser is the upper 3 ft. of the shell and tube and the lower two pipes of the double pipe condenser.

Use of Brine: Direct Expansion.—There does not appear to be any definite rule in regard to the use of brine or direct expansion. The use of direct expansion means a lesser cost of

operation inasmuch as the suction pressure required will be less when cooling brine in order that the latter may be used to cool air, or other substances to be refrigerated than when the evaporating coils are used directly for the desired cooling. Such a double cooling means that more horse-power per ton of useful refrigeration is required than with direct expansion. However, brine makes it possible to have considerable flexibility and more safety. A brine spray may be used for cooling air, or brine storage may be utilized for the purpose of storing up refrigeration to be used to carry the load during a "peak" or during the intermittent operation of the refrigerating machine. The meat-packing organizations use brine in the majority of cases, whereas cold storage plants frequently use direct expansion if the system is self contained. District cooling plants, as found in certain localities in large cities, prefer brine because of the reduced danger due to leaks, loss of refrigerant and excessive pressure drop in the long suction lines.

The kind of brine is confined to calcium and sodium chloride, and the former is used where temperatures of 10° F or lower are required, because of the ability of calcium chloride to take low temperatures without freezing. The corrosive action of brine with respect to metals is a very moot point. As a rule there is little tendency for "corrosion" if the brine has a specific gravity of 1·2 and is kept neutral or slightly alkaline. The use of mixtures of several salts is very unwise as this tends to corrosion. It has been found also that any brine which is unstable in character and tends to become acid will be bound to cause excessive "corrosion." The best means of preventing corrosion in the open or closed brine systems is to use sodium dichromate in sufficient quantities to make the brine slightly alkaline. Zinc dust may be used to advantage in open calcium chloride brine circuits.

The Automatic Refrigerating Machine.—The small refrigerating machine has to be automatic in every sense of the word. In order to do this the machine must be thermostatically controlled so as to start and stop with a slight change of the temperature of the commodity to be refrigerated. The automatic controls which are required in order to have a successful automatic refrigerating machine of the compressor type are: (1) a suitable thermostat, (2) a means of controlling the evaporating pressure, (3) a condensing water control, if the water cooled condenser is used, (4) an excess pressure shut-off.

The thermostat (*q.v.*) is usually of the metallic coil or the volatile liquid bulb and bellows type. In either case a change of temperature causes a motion of a contact point or of the arm of a lever sufficient to cause the make or break of an electric circuit. The latter may be direct on the motor line or it may operate a relay switch. The evaporating pressure is controlled either by means of a float valve, operated either on the condenser pressure or the suction pressure side of the system or by means of a pressure reducing (expansion) valve. The expansion valve is of the needle valve principle, using a spring loaded diaphragm. Variation of the suction pressure may be obtained by a manual control of the tension of the spring. The water pressure control may be from the principle of the temperature of the water leaving the condenser which acts on a bellows filled with a volatile liquid or on the principle of a spring loaded diaphragm subjected to the condenser pressure. Finally the excess pressure shut off is another loaded diaphragm so connected as to break the electric circuit should the pressure become greater than the safety limit.

Household Refrigerating Machine.—The household refrigerating machine is simply an adaptation of the automatic principles just enumerated. The refrigerating machine is very nearly always a reciprocating compressor with either one or two cylinders. The use of the absorption machine with either electric or gas heat has been advocated but has not been adopted by the public to any extent. When the latter is used it is intermittent in action except in the case of the machine using an inert gas in the evaporator side in order to overcome the necessity of the use of an expansion valve.

The household machine uses sulphur dioxide nearly always as the refrigerant. (*See* REFRIGERATORS, HOUSEHOLD.)

Heat Transfer.—The subject of heat transfer is of the greatest importance in refrigerating industries. In cold storage plants it is necessary at times to install a thickness of 8 in. or more of corkboard on the walls, ceilings and floors. The best insulation for cold temperatures is one that is water-proof, that has a low value for the coefficient of heat transmission and is easily erected in place. The low value for the heat transmission is obtained by means of small air cells in the structure as is found in cork, wood and vegetable products, mineral wool and hair felt. The insulating property of the material is obtained from the effect of the air cells which are so small as to prevent convection currents, and so the statement is frequently made that the material which has the greatest number of air cells has the greatest value as an insulator. However, in refrigeration, the tendency is to absorb moisture from the air and to have it collect on the coldest surface. Therefore the material must be made waterproof if it is not so naturally. Saw-dust, shavings and materials of a compressed vegetable nature like corn stalks, sugar cane stalks, straw, etc., are suitable as heat insulators providing they are waterproofed. As this is not practical in a number of cases except by the use of waterproof paper such construction is not used in the best installations.

Formula for Heat Transfer.—If the value k of the coefficient of heat transfer is known in B.T.U. per square foot per one degree difference of temperature per hour then the total heat transfer per hour is found by $Q=Akt_m$ where Q is the total heat transfer in B.T.U. per hour, A is the area of the surface in square feet and t_m is the temperature difference on the two sides of the surface. The coefficient of heat transfer (k) must be found by experiment and certain of these are given in Table III. If a built up structure is used, composed of several thicknesses of material then the formula usually employed is:

$$k=\frac{1}{\frac{1}{F_1}+\frac{1}{F_2}+\frac{T_1}{C_1}+\frac{T_2}{C_2}}$$

where T is the thickness of each material in inches and C is the coefficient of conductivity in B.T.U. per 1 inch thick.

TABLE III.—*Coefficients Based on Heat Transmission Tests (B.T.U. per Hour)*

(From Bulletin 102, Eng. Experiment Station, University of Illinois, by Willard and Lichtz)

Material	C per 1 in. thickness per square foot per 1° F	F Still air per 1° F
Brick wall (mortar bond and dry conditions)	4·00 (5·00)	1·40
Concrete, 1–2–4 mixture	8·30	1·30
Wood (fir, one surface finished)	1·00	1·40
Corkboard	0·32	1·25
Magnesia board	0·50	1·45
Glass (actual glass 91·4% of total area)	2·06	1·5 to 2·00
2 in. tile, ½ in. plaster on both surfaces	1·00	1·10
4 in. tile, ½ in. plaster on both surfaces	0·60	1·10
6 in. tile, ½ in. plaster on both surfaces	0·47	1·10
2 in. tile, plastered as above and roofing covered	0·84	1·25
Asbestos board	0·50	1·60
Sheet asbestos	0·30	1·40
Double glass, ½ in. air space (glass 69·3% of total area)	1·50**‡	2·00
Roofing*	5·30‡	1·25
Air space†	1·00–1·70‡	..
Mortar	8·0	0·93
Shavings	0·42	..

*Calculated from values of C for 2 in. tile with and without roofing. $\left(\frac{1}{C}=\frac{1}{C_1}+\frac{1}{C_2}\right)$

†*See* "Air Spaces."

**Per square foot of actual glass set in wood frame but based on total heat transmitted.

‡For thickness and construction stated, not per 1 in. of thickness.

It has been found that the surface film offers a high resistance to the transmission of heat and in the formula the values F_1 and F_2 refer to this surface resistance. For outside weather conditions it is usual to consider the value of F_2 as equal to $3F_1$.

The coefficient of heat transfer (k) for refrigeration piping is

Material	Conductivity, B.T.U. per square foot per degree difference of temperature per hour	Density	Nature of material
Air	0·167	..	Horizontal layer heated from above
Colorax	0·221	0·064	Fluffy, finely-divided mineral material
Hair felt	0·246	0·27	Hair felt between layers building paper
Keystone hair	0·271	0·30	..
Pure wool	0·242	0·107	Firmly packed
Pure wool	0·242	0·102	Firmly packed
Pure wool	0·262	0·061	Loosely packed
Pure wool	0·292	0·039	Very loosely packed
Cotton wool	0·292	0·100	Firmly packed
Insulite	0·296	0·19	Pressed wood pulp
Corkboard (pure)	0·317	0·18	..
Granulated cork	0·34	0·100	..
Eelgrass	0·321	0·25	Inclosed in burlap
Flaxlinum	0·329	0·18	Vegetable fibres, firm and flexible

TABLE IV.—*Values for the Coefficient of Heat Transfer for Piping* (B.T.U. per sq. ft. per degree difference of temperature per hour)

	B.T.U.
Can ice making piping	
Old style feed, non-flooded	12 to 15
Flooded	20 to 40
Ammonia condensers	
Submerged	30 to 40
Atmospheric, gas entering at the top	60 to 65
Atmospheric, drip or bleeder	125 to 200
Flooded	125 to 150
Shell and tube	150 to 300
Double pipe	150 to 250
Baudalot coolers, counter-flow, atmospheric type	
Milk coolers	75
Cream coolers	60
Oil coolers	10
Water coolers (for direct expansion	60
Water coolers (for flooded	80
Brine coolers	
Shell and tube	90 to 100
Double pipe	150 to 300
Cooling coils	
Brine to unagitated air	2 to 2¼
Direct expansion	1½ to 2
Water cooler, shell and coil	15 to 25
Liquid ammonia cooler, shell and coil accumulator	45
Air dehydrator	
Shell and coil (brine in coil) (1st coil	5·0
Shell and coil (brine in coil) (2nd coil	3·0
Double pipe	6 to 7
Superheat remover, shell and tube	15 to 25

extremely important, but is known to a slight degree only. The reason for this is that a large number of values are obtainable unless exactly the same conditions exist in each case. The value of k is influenced to a very large degree by the effect of stagnant films of fluids adjacent to both surfaces, to the kind of material, the kind of fluid on either side of the metal, the amount of scale or dirt on the surfaces and particularly on the velocity of flow of the fluids receiving or giving up heat to the metal. In calculating piping the best that can be done, then, is to give average values for k or a range of values which can be obtained by altering the conditions either by the velocity of the water, brine or other fluid past the heat transfer surface, the mean temperature difference on the two sides of the surface or by cleaning the surface. Table IV. gives values usually accepted in good practice. The surface of the piping is usually taken as the outside surface, except for ammonia condensers where the surface is taken as that adjacent to the refrigerant.

Methods of Cooling.—Mechanical refrigeration as is understood at the present time means the absorption of heat by a volatile liquid in consequence of which the liquid boils. The usual method of procedure is to use direct expansion piping whereby the liquid boils in the pipes situated in the rooms to be cooled, or by first cooling brine and then by circulating the brine through the piping. The arrangement of the piping may be along the walls or under the ceiling one example of which is shown in fig. 3. In cold storage refrigeration natural air circulation is resorted to almost entirely, in which case the velocity of the air in contact with the pipes is very low thereby resulting in a low value of the coefficient of heat transfer.

In some exceptional cases a bunker room is installed. Such an arrangement of piping, which may be in an ante-room, a corridor or in a separate room, is the suitable nesting of the piping in an enclosure whereby the air may be forced past the piping and into the room. The bunker system requires, then, a forced circulation of the air. The advantages are in being able to use less pipe and in being able to keep the refrigerant out of the room if such a matter is an asset. The disadvantages are in having to provide power for circulation and in the difficulty in cleaning the piping should frostation accumulate.

At times there is an advantage in having a hold-over arrangement of tanks, as shown in the figure as 8 in. tubes. By this

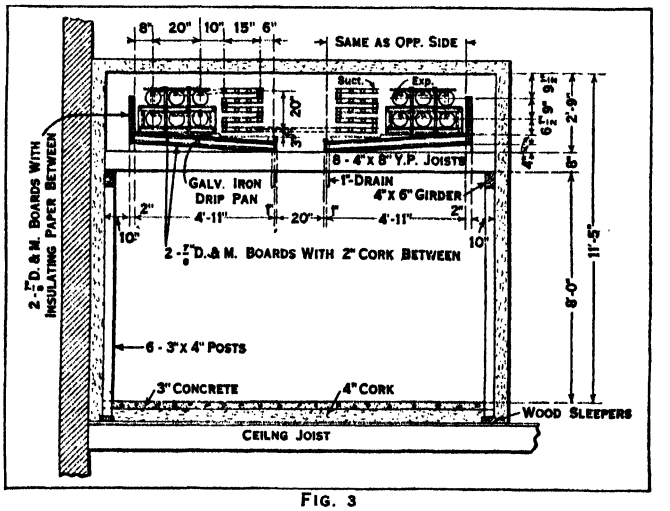

FIG. 3

scheme the brine in the tubes is cooled during the day time operation of the refrigerating machine and this cold brine will assist in holding the temperature by absorbing the heat generated by the effect of heat leakage, chemical action of the various commodities, etc.

When brine is used the method of cooling is by the use of the multi-pass shell and tube brine cooler. Such an apparatus has the brine inside the tubes, which are usually 2 in. in diameter and it is designed for 2, 4, 6 or 8 passes of the brine. The ammonia is inside the shell and its boiling action is similar to that of the

horizontal return tubular boiler in the generation of steam. The gas-releasing surface and the gas volume are sufficient to prevent the liquid returning through the suction pipe line to the compressor. Besides the shell and tube brine cooler the shell and coil and the double pipe designs are used for carbon dioxide installations and the double pipe for ammonia. In the case of carbon dioxide the unit pressure is so great that the refrigerant is kept inside the pipes.

APPLICATIONS OF REFRIGERATION

Refrigeration has developed from its application in the brewery industry and more or less academic uses in other directions to a very important economic position. The ice-making industry is now ninth in the amount of invested capital in the United States. Without it natural ice would be a luxury in all except those localities exposed to severe winter conditions, and modern meat packing, the supply of fresh fruit and vegetables out of season, marine refrigeration and modern industry, where a depressed temperature and air conditioning are required, would each be an impossibility. Some details of a few of these applications are described below.

Cold Storage.—Cold storage is one of the essential uses of mechanical refrigeration. By its means the season for fruits and vegetables is increased from a few weeks to from four to six months. Eggs may be kept from the period of great plenty in the early spring until fall if necessary, whereas the modern meat packer could not exist without refrigeration. In the latter case the animals are slaughtered under hygienic conditions and the meat is promptly chilled or frozen. Conditions of handling and holding the carcasses are as ideal as possible and shipment may be made in refrigerator cars to the retail trade. The space in the United States cooled mechanically to 40° F or lower for all kinds of cold storage work, exclusive of the packing house, is estimated at 700,000,000 cu.ft., with an estimated invested capital of $200,000,000.

Some indication as to how this may affect the modern city may be obtained from the statistics for New York city, where the following car loads of perishables are consumed each week: Dairy products 200; milk 2,200; meat 750; live stock 600; poultry 300; fruit 850; vegetables 1,750; sea food 50; totalling 6,700 car loads. The usual practice in regard to the temperatures, specific heats and tolerances will be seen by consulting the following table.

TABLE V.—*Composition and Specific Heat of Food Products and Storage Temperatures*

Product	Temperature carried	Composition, per cent		Specific heat above freezing	Specific heat below freezing	Latent heat of freezing
		Water	Solids			
Lean beef	30	72·00	28·00	·77	·41	104
Fat pork	30	39·00	61·00	·51	·30	56
Eggs	30	70·00	30·00	·76	·40	101
Potatoes	34	74·00	26·00	·80	·42	107
Cabbage	33	91·00	9·00	·93	·48	131
Carrots	33	83·00	17·00	·87	·45	120
Cream	33	59·25	30·75	·68	·38	85
Milk	35	87·50	12·50	·90	·47	126
Oysters	35	80·38	19·62	·84	·44	116
Whitefish	15	78·00	22·00	·82	·43	112
Chickens	28	73·70	26·30	·80	·42	106
Ice	28	100·00	0·00	1·00	·504	144

The Packing Plant.—The total refrigerated space in the packing plants of the United States in 1921 amounted to 258,549,000 cu.ft., which included 443 plants, of which 15,400,000 cu.ft. were held at 10° F or lower, 18,300,000 cu.ft. held at temperatures ranging from 11° to 29° F and 200,000,000 cu.ft. held at temperatures ranging from 30° to 44°. According to the U.S. Government reports 63,415,000 animals were slaughtered in 1920 under Government inspection including 7,600,000 cattle, 3,800,000 calves, 13,000,000 sheep and lambs and 39,000,000 hogs. Not less than 80% of these require refrigeration for a short time at least although the average time is between one and two months, and

Approximate Cold Storage Temperatures

Article	Temperature, degrees F	Article	Temperature, degrees F

Cold Storage Practice

Temperature of storage, degrees F	Humidity, per cent	Allowances
..	..	1 bbl. = 31½ gal. of 231 cu.in. each
..	..	1 bushel = 1·245 cu.ft. = 2,150·4 cu.in.
35	80 to 90	1 bbl. potatoes = 5 cu.ft. = 180 lb. = 2½ bu.
32 to 34	70 to 80	1 box cheese = 60 lb. = 2 cu.ft.
30 to 31	75	1 case eggs = 30 doz. = 50—70 lb. = 2¼ cu.ft. = 12×13×25
2 or lower	70	1 tub butter = 63 lb. = 1½ or 2 cu.ft. (piles not over 6 ft.)
30 to 35	85	1 bbl. apples = 150 lb., 5 cu.ft. = 2½ bu.
34	80 to 90	1 crate celery = 10 cu.ft. = 140 lb. = 24×24×30 in. (8 ft. high)
34	80 to 90	1 bbl. vegetables = 5 cu.ft., piles 5 ft. high
35	80	1 box oranges (packed on end) = 4 cu.ft., 70 lb. = boxes 15×15×30

Aisles—Allow ¼ for eggs, celery and oranges
Allow ⅓ for potatoes and vegetables
Allow ¼ for mutton, pork, poultry (4 ft. high)
Specific gravity of boned beef = 1,073 = 67·2 lb. per cu.ft.

the average time between slaughtering and the consumption of the meat is less than two months. A very small amount (5%) of the meat is frozen and is held in freezer storage.

Method of Cooling.—The method of chilling meats just received from the killing floor is not standard. As a rule the loft system is used, this upper portion being separated from the storage room below by means of a false ceiling. When brine is used it may be passed through pipe coils, or it may be made to come into actual contact with the air in the form of a finely divided spray, using a nozzle similar to that used in the washing and conditioning of air. By this means an intimate mixture of air and brine is obtained inasmuch as the air has to pass through a curtain of finely divided brine. The air in the room is kept in constant circulation by the flow of the brine and the temperatures of the air in the different parts of the room are almost uniform. Where head room does not permit the use of a spray loft, the brine tube or brine box system may be used to advantage. In these cases the brine spray is confined to a limited space and the air has a forced circulation on account of the action of the sprays. Table VI. shows some statistics in regard to existing plants. Storage space may be piped in the usual manner.

Marine Refrigeration.—Marine refrigeration has four kinds of refrigeration equipment: (1) Fruit carriers require forced circulation of cool air with some fresh air, (2) Frozen meats which require no air circulation but do require good insulation and a storage temperature of from 12° to 15° F, (3) Chilled meats require a heavy piping ratio with the pipes located under the ceilings. The temperature of the cold storage rooms must be controlled within a small temperature variation, (4) Where general cargoes are carried the frozen meats may be carried in the lower holds.

TABLE VI.—*Wholesale Meat Markets*

District Cooling.—Large cities which have segregated cold storage warehouses, commission merchants and retail markets find it convenient to have a central cold storage company which will supply refrigeration under contract. Of these the Quincy Market and Cold Storage Warehouse Company of Boston, Mass. and the Merchants Refrigerating Company of New York are the best known. The former started under the direct expansion system but as the company expanded a change was made to brine, and in 1927 there were 1,400 separate services with 1,500 tons of refrigeration of connected load, exclusive of the warehouse service. The Merchants Refrigerating Company has brine at 0° F and carries 400 services varying from 200 to 15,000 cu.ft. of cold storage of which 35% is freezer and 65% is cooler space at from 31° to 35°.

The piping, where brine is used, can be full weight steel or wrought iron pipe usually completely welded between man-holes. Expansion joints must be provided every 500 ft. at a maximum, located at man-holes, and they may be of the slip joint, the corrugated or of the U type. The pipe must be placed below the frost line, usually from 3 to 7 ft. below the surface.

Ice Making.—The manufactured ice industry of the United States is one that was estimated in 1924 to comprise an investment of $1,000,000,000. Its importance has developed because of the hot summer conditions in the United States and because of the uncertainty and the cost of transportation of natural ice. Although the fractional tonnage compressor had removed a large number of the larger ice customers and the household refrigerating machines have caused a loss of thousands of residential customers, yet the manufactured ice industry has shown an increase of output of about 10% yearly. The natural ice trade was almost negligible in 1928 except in certain regions where ice is cut for car icing or similar purposes.

There have been numerous methods of freezing manufactured ice but the only method now installed in the United States is the "can system." In the "can system" the water to be frozen is placed in galvanized iron cans which are lowered into a brine at a temperature of from 14° to 17° F. The water in the cans may be either distilled water or drinking (so-called *raw*) water. One of the peculiarities of the American requirements is that the ice must be transparent. With distilled water it is very easy to get a crystal ice, but raw water cannot be made transparent without agitation and water softening because of the air in solution as well as the bicarbonates and other solids in solution in the water.

Distilled Water Ice.—In the case of the steam driven compressor the condensate is available, after elaborate reboiling and filtering, for the filling of the ice cans. Such ice is called distilled water ice and it makes a crystal cake of ice without difficulty. However a steam plant must be used thus meaning the installation of suitable steam boilers, engines and condensers. The economy of the steam engine would not be an important factor because enough distilled water must be obtained to fill the cans unless a multiple effect evaporator is used in addition to the steam engine. This uneconomical use of power, however, does not compare favourably with other designs as for example the oil engine or the electric motor driven compressor using raw water in the cans.

Raw Water Ice.—The difficulty with raw water ice, as has been mentioned, is in the treatment of the water to be frozen. The problem is not a difficult one if the water is rain water and in some localities even the non-thermal deep wells are not objectionable, whereas in other localities as for example in Indiana, Illinois, Iowa, etc., the number of grains of bicarbonates, sulphates, etc., may be as high as 30 to 40 per gallon. As such water is frozen the solids in solution become more and more concentrated until finally some of these are precipitated. In addition there is the air in solution which of itself would cause an opaque ice should freezing be carried out without using some method to prevent the air bubbles from settling on the freezing surface and freezing into the ice.

One of the first concerns of the ice manufacturer is that of water purification and softening. The requirements of first quality ice are clearness, firmness and freedom from discoloration. One of

the best methods of securing this is by the use of the lime-soda ash filter (the water being cold of necessity), followed by a sand filter and an alum coagulator Softening with lime removes the bicarbonates effectively. It is not necessary to remove all the permanent hardness provided that the magnesium which always tends to cause whiteness in the ice is removed. As a general statement if the sum of the sulphates, chlorides and nitrates does not exceed 20 grains per gallon the water may be purified for ice making, if the number of grains range from 20 to 40 per gallon the results are doubtful but if they exceed 40 grains the water will be found to be unsatisfactory for ice making. Up to 12 grains per gallon of solids consisting of sulphates, chlorides, nitrates and sodium carbonates the so-called low pressure air agitation system will give good results whereas if the high pressure air system of air agitation is used the solids may be increased to 20 grains and as good results can be obtained as with 12 grains and low pressure agitation.

Air Agitation.—By low pressure air agitation is meant that air under about 3 lb. per square inch is supplied by means of a small seamless brass drop pipe to the water in the cans which are usually of the 300 or the 400 lb. size and have a cross section of 11 by 22 inches. The amount of air delivered to the can is about 0·5 cu.ft. of free air per minute which is supplied at about 12 in. from the bottom of the can. The drop pipes may be removed towards the last of the freezing process or they may be frozen into the cake of ice in which case they are thawed out by means of a steam needle. In the latter case the tube is perforated with small holes at several points in order that agitation of the core water may continue after the end of the tube is frozen up by the formation of ice at the bottom of the can.

If the tube is soldered into the corner of the can or along the side by crimping the can enough to permit the tube to be soldered flush with the side of the can then the air tube becomes an integral part of the can. In such a case the air has to be dehydrated for otherwise the moisture in the air will freeze and will prevent all agitation. The dehydration is achieved by means of precooling the air under a pressure of about 25 lb. gauge if the air is supplied to the cans at 15 lb. per square inch and 0·2 cu.ft. of free air is supplied per minute per can. For cooling the air usually a brine spray or brine coil is employed, the brine used being taken from the ice tank.

Harvesting.—The American practice is to lift, dump and fill with water a number of cans at a time. This number may be 5, 6, 10 or even 30 cans, in which case a can basket is used for holding the cans securely at all times.

Cooling the Brine.—The brine in the tanks may be cooled by having direct expansion piping in the brine between the cans, or by the use of brine coolers. The old form of direct expansion piping was very inefficient because of the disregard of the principles of heat transfer. Improvements have been made of recent years by reducing the length of the coils so as to permit the gas formed by evaporation of the refrigerant to return quickly to the compressor, by the use of the flooded system whereby the coils are kept much more full of liquid refrigerant and by the use of an accumulator or other device to precool the liquid from the condenser to the temperature of evaporation before the liquid enters the evaporating coils. The accumulator acts also as a liquid trap to prevent liquid returning with the suction gas to the compressor.

Cooling of Air.—One of the great applications of refrigeration is that of air conditioning and cooling. In industries a uniform relative humidity of 60% is frequently called for, combined with a dry bulb temperature of 65° or 70° F. In the case of theatres the main purpose is to make the auditorium *feel* cool. This is done best by reducing the relative humidity and at the same time cooling the air some 5° or possibly 10°. In the theatre a certain amount of air must be supplied per person; this amount being from 25 to 30 cu.ft. per minute per person. The air may be recirculated in part and the remainder may be fresh air depending on the local laws or conditions, but in either case all the air must pass through a water sprav chamber before it enters into the room to be ventilated

Milk and Ice Cream.—Milk, after being pasteurized, must be cooled from about 140° F to 70° with water and then to 40° by means of brine. The cooling of the milk should be accomplished as promptly as possible and the method has been to use the Baudolet cooler with the brine inside the pipes and the milk flowing on the outside. In ice-cream (*q.v.*) making refrigeration is used both in the freezers and in the so-called sharp freezers which are held at about 0° F. The freezers are power-driven and they may be cooled by means of brine or by direct expansion piping. (*See* also FOOD PRESERVATION; HEATING AND VENTILATION; AIR CONDITIONING; THERMODYNAMICS.) (H. J. MAC.)

REFRIGERATORS (HOUSEHOLD). These appliances may be classed in two groups: (1) those depending on natural or artificial ice as the cooling or freezing medium and (2) those fitted with a heat extracting apparatus.

In the first group are the small ice boxes or chests, low in first cost and having wood or metal cases. The cheapest of these have very little insulation and make no particular claim to efficiency. The more expensive models are better insulated and are usually lined with vitreous porcelain. Melting ice in a well insulated box, having one-third or one-half of its capacity devoted to ice storage, can maintain a temperature of from 42° to 48° Fahrenheit at a cost which compares very favourably with other methods of refrigeration.

In the second group are the various types of household refrigerators depending on some internal heat extracting equipment.

The two principal methods of artificially reducing temperature are known as the compressor system and the absorption system.

In the United States the compressor system is the one in general favour for household use. Refrigerators using this system have a small electric motor, usually of one-quarter horse power, which drives the compressor. The compressor is placed (1) under the refrigerator cabinet or (2) anywhere within 50 ft. of it, provided there is a fall from the cabinet to the compressor.

When it is desired to begin refrigeration, the electric motor is switched on, and the compressor commences the cycle of operation. The refrigerant in the cooling coils, owing to the warmer temperature in the box, vaporizes and in doing so extracts heat from its surroundings. The refrigerant, having absorbed the heat, leaves the cabinet and passes through a copper tube to the compressor or pressure pump, the action of which, in conjunction with the cooling or condenser coil, converts it back to a liquid. The heat is automatically released and the liquid refrigerant is then re-admitted to the cooling coil so extracting more heat and repeating the process.

The most widely used refrigerant is sulphur dioxide (SO_2) because it is a stable gas, is non-toxic, non-inflammable, and as a refrigerant has many advantages over other gases as it admits of low pressure operation. Other refrigerants used are ethyl chloride, ammonia, carbon dioxide and methyl chloride.

One of the principal advantages of the compressor type of household electric refrigerator is that the automatic control of the electric motor can be set to produce the temperature desired. When the temperature in the refrigerator rises slightly above the set temperature, the motor automatically starts. When the temperature in the box drops slightly below this point, the motor stops, thus maintaining an even temperature in the box.

There are two types of cooling controls in general use. One type operates with an expansion valve and is called the "dry system." The other type, in which a relatively large amount of

liquid refrigerant is retained in the evaporator, is the "flooded" system.

In these systems the gas passing through the coils is cooled by a fan attached to the motor. This method of cooling has been found to be sufficiently efficient for boxes up to 50 cubic feet capacity.

In Great Britain and Europe, a widely used method of obtaining refrigeration is an apparatus which does not require the use of motors or pumps. In this apparatus, heat is applied to a boiler containing a solution of ammonia in water, the ammonia being expelled from solution in gaseous form and then condensed to liquid by external cooling air or water. The liquid ammonia enters an evaporator located in the cabinet and there evaporates to reduce temperature. The now gaseous ammonia passes into the absorber, where it meets the water coming from the boiler, and the ammonia is absorbed again by the water, which is returned to the boiler.

The necessary difference in pressure of ammonia in the boiler-condenser part of the system and the evaporator-absorber part is provided by the use of hydrogen, which automatically circulates because of the difference in weight of two gas columns. The ammonia solution in the absorber is pumped back into the boiler through a pipe constantly heated.

The advantages of this type of absorption machine are that it can be operated by electrical, gas or oil heating. (*See* REFRIGERATION AND ICE MANUFACTURE.) (G. E. W. C.)

REFUGEES AND THE EXCHANGE OF POPULATIONS. In the early history of European civilization wars and conquests were often followed or accompanied by considerable movements of population. Sometimes the two went necessarily together, because the motive for war was the desire for richer lands on which the conquerors wished to live; sometimes the movement of population resulted from the ferocity of the invaders who drove whole populations away from the countries which they had inhabited.

REFUGEE MOVEMENTS

Temporary.—For a long period this feature of warfare disappeared, but with the World War of 1914 it once more recurred. The events of 1914–18 caused greater movements of population from one place to another than there had been for centuries before. In some cases, it is true, these movements, though large, were only temporary. For example, although the Belgian refugees who fled from the German invaders in 1914 were very numerous, and although practically all of them remained away from their homes until the end of 1918, they did not attempt to create a new life or to establish new homes outside their native land; their migration was only temporary, like that of the refugees who fled from the invaded provinces of France, Italy and Rumania, and to a smaller extent from all the territories occupied by enemy troops during the war.

Permanent.—But in other cases, great masses of refugees who left their homes when the tide of war swept over them had little prospect of ever returning or of recreating their previous life there. This has been the situation of a considerable proportion of the inhabitants of the Balkan peninsula. In that unhappy region of the world, where the population of large areas is mixed in race, great masses of people were obliged, either by fear of the invading armies or by the hostility of their immediate neighbours, to fly from the places where for centuries they and their forefathers had lived, and once they had left their homes the Governments of the countries which they had abandoned made it plain that they would not allow them to return, or would only allow them to return on conditions which the refugees considered altogether unacceptable. Faced, therefore, with prolonged, if not permanent exile, the refugees were forced to try to build up a new life in the countries to which they had fled. This happened in one case as the result, not of international, but of civil war. The struggle of 1917 to 1919 between the White and Red armies in Russia led to the emigration of one and a half million Russians who in the first instance sought refuge in the countries bordering on Russia, but subsequently, thanks to the action of the League of Nations, were for the most part enabled to settle more or less permanently in 45 countries throughout the world. In yet other cases the movement of population took place, not as the direct result of military action during a war, but in consequence of the terms of the treaties made when the war ended. But whether they came about under the terms of these so-called "exchange of population" treaties, or whether they were due to the compulsory or spontaneous flight of terror-stricken minorities while hostilities were still going on, these movements of population were due directly to the war. They all presented a number of common features, while collectively they created great economic, social and political problems for the exhausted Governments of Europe. Before indicating what has been done to deal with this problem it is necessary to say a few words about its extent.

MOVEMENTS—VARIOUS COUNTRIES

Excluding such temporary movements as those of the Belgians, the emigrations of war refugees of different nationalities were roughly as follows:—

1. **Russians.**—Between 1917 and 1920 nearly one and a half million political refugees from Russia were thrown upon the charity of Europe. Some of these refugees were prisoners taken by the Germans and Austrians during the war, who refused to return to Russia. A great number were members of the defeated armies of Koltchak, Wrangel, Denikin and others. Many of the refugees were women and children who fled from the Bolshevist revolution. In the earlier days of their exile they were dispersed as follows: Germany 300,000, Poland 400,000, France 400,000, Constantinople 100,000, Yugoslavia 50,000, Bulgaria 30,000, Czechoslovakia 26,000, Rumania and Greece 50,000, Baltic States 100,000. In addition a large number, at least 100,000, fled eastwards into China.

2. **Greeks.**—As the result of warlike operations there fled into Greece between 1915 and 1922 1,250,000 Greek refugees from Asia Minor and eastern Thrace and 50,000 from Bulgaria. In addition there came under treaties for the exchange of population from Bulgaria a further 50,000; from Asia Minor approximately 100,000.

3. **Armenians.**—From the year 1915 onwards there were expelled from their dwellings in Asia Minor some hundreds of thousands of Armenians. Great numbers of them perished in their wanderings in the mountains; some thousands succeeded in making journeys on foot as far as Mesopotamia; others sought protection in the Russian empire. In 1921 the independent Armenian republic of Erivan, with an Armenian population of 800,000, adopted the Soviet régime and became part of the Federated Union of Socialist Soviet Republics. To its original population, 300,000 to 400,000 additional refugees from Turkish Armenia were shortly added, and in spite of their great suffering, they were absorbed with remarkable rapidity into the economic system of the country. It is further estimated that more than 300,000 other Armenians are scattered more or less in destitution over Russia and the Near East, particularly Bulgaria and Greece. In 1921 100,000 fled to Syria, many of whom have now become Syrian subjects in the territory under French mandate; more than 60,000 fled in the following year to Greece, 35,000 to Bulgaria and 20,000 to 30,000 more fled to the Republic of Erivan.

4. **Bulgars.**—From 1918 onwards a large number of minorities of Bulgarian or quasi-Bulgarian race and language fled from their homes in the Dobrudja, in Macedonia and in eastern and western Thrace. It is calculated by the Bulgarian Government that their total number amounts to almost half a million. In addition, about 75,000 Bulgars have voluntarily emigrated to Bulgaria from Greece under the terms of the Greco-Bulgarian Exchange of Populations Treaty.

5. **Turks.**—Approximately 50,000 Turks fled from eastern Thrace and Smyrna when these territories were occupied by Greek forces in 1919, but returned to their homes in 1922. In addition approximately 350,000 to 400,000 Turks were moved from Greece (most of them from Macedonia, Crete and western Thrace) to Asia Minor under the terms of the Exchange of Populations Treaty made at Lausanne in 1923.

EFFECTS OF REFUGEE MOVEMENTS

Broadly speaking, the general features of these movements of population may be summarized as follows:—

The great emigration of Russian political refugees was, in the first instance, regarded as an almost unmixed evil both for Europe and for the refugees themselves. Their great suffering was not, in the early stages, compensated by any considerable political or economic gain. This is not equally true, however, of the movement of population in the Balkans and in the Near East. These movements have at least done a great deal towards the effective unmixing of the populations in these areas. The mixture of populations has led to so much political trouble in modern times that this unmixing process must be regarded as a very considerable advantage.

Further, in certain countries the influx of refugees, while at first it appeared to be a disaster, is in the long run proving to be a source of strength. This is particularly true of Greece, where, thanks to arrangements which will be mentioned shortly, the refugees were absorbed very quickly into the economic system of the country, where they have immensely increased the agricultural production and have imported industries hitherto unknown. There is no doubt that they have thus much improved the political position of Greece by giving it a homogeneous and vigorous new population and by increasing the economic wealth of the nation as a whole. It appears probable that the same result will in due course happen in Bulgaria, though there the process has been much slower, as the refugees showed less inclination to accept their exile as definitive and to settle down in new homes, than those who went from Asia Minor to Greece.

Another result of general importance which has followed the movement of population caused by the war is that Asia Minor has been left almost exclusively to the Turks. Hitherto inhabited by a very mixed population, including elements which continued the traditions of the ancient civilization of Byzantium, there are now few of these elements left. Furthermore it should be noted that the Russian emigration, which, as already stated, was regarded as an unmixed evil for the refugees and for the countries offering them hospitality, is, under the guidance of the League of Nations and the International Labour Office, beginning, in certain countries, especially France, to constitute an important reconstructive economic factor.

These changes, whether they be good or evil, have only come about at the cost of terrible suffering to all the individuals concerned. This is true even of those who have been moved under treaties of exchange though of course their sufferings have been much less than those who fled before invaders. It is the personal aspects of refugee movements which generally dominate the minds of people when they consider refugee questions; and no doubt these personal aspects are of supreme importance, not only on account of the claim of the refugees to the humanitarian sympathy of every civilized man and woman, but also because it is the personal problems of individual refugees, which, when they are taken collectively, make up the economic problems which their movements cause. And the economic problems brought upon the Governments of Europe by refugee movements since the war have been of great importance. In many countries they have seriously over-flooded the labour market, and in a number of centres the arrival of vast masses of strangers, wholly destitute and unable to find employment, threw a great burden on the financial resources of the States to which they came, whose Governments, unwilling to see them die of starvation, were literally obliged to furnish them with doles from their national funds. This part of the problem is, however, much affected by the so-called Treaties for the Exchange of Population, on which, therefore, it is necessary to say a word.

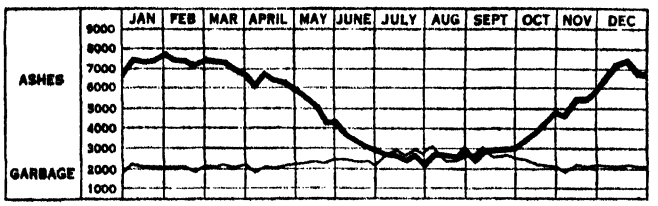
Treaties of Exchange.—Under these treaties, the most important of which are the Greco-Turkish and the Greco-Bulgarian, impartial committees, consisting of one representative from each Government and two or three impartial experts appointed by the League of Nations, supervise or actually carry out the transportation of the persons moved from one country to the other, value their property, keep an exact record of it and establish their claim for this value against the Government of the country to which they go. These treaties of exchange have worked with varying success. So far as the Greco-Turkish Treaty is concerned, its principal and most necessary effect was to make room in Greece, by the removal of 350,000 Turks, for a great part of the incoming flood of refugees, who found in the evacuated Turkish properties fields and houses ready for their use. Without this treaty of exchange, and without a refugee settlement loan floated under the auspices of the League, the absorption of the Greek refugees into productive employment in their motherland could never have been done. On the other hand, the fate of the Turks transported under the treaty from Greece into Turkey and in the absence of such a loan, appears to have been less happy. Official information cannot be had, but it is obvious that the arrival of 350,000 refugees in a country whose total population does not exceed five millions, must necessarily impose a heavy burden on its resources already straitened by many years of war.

Of the Greco-Bulgarian treaty of exchange, it is enough to say that while the working of its machinery has been slow, it has already laid the foundation for an unmixing of the population in Greek Macedonia and in parts of Bulgaria, which in the long run, though at the cost of great personal suffering, is likely to lead to satisfactory results.

WORK OF THE LEAGUE OF NATIONS

The other personal and economic problems which have been raised by the refugee movements above described have been dealt with partly by individual Governments and partly by the League of Nations. To take the Russians first, many Governments throughout Europe accorded them particular privileges and gave them much State help, estimated at £2,000,000 per annum—in particular Yugoslavia, Czechoslovakia and Bulgaria deserve mention. The League of Nations and the International Labour Office also played a considerable part through the action of the delegations established in Constantinople and in the Baltic States, Rumania, China, Bulgaria, Greece, Serbia, Germany, Poland, France and other countries, in breaking up the most disastrous congestions of refugees in places where no employment could be found, for example, in Constantinople and Greece, in placing some hundreds of thousands in employment in no fewer than 50 different countries; in securing for the refugees in many countries legal protection, freedom of movement in search of employment and a new form of so-called "League of Nations Passport" which has secured the recognition of over 50 Governments, under which they were enabled to travel from one country to another; and even in securing for a small number who desired it, repatriation to their native land. Under the auspices and with the help of these League offices, large movements of Russian refugees were carried out to France, where some thousands have been settled as tenant farmers and in industry, to the United States, to Canada, to South America and to other countries where employment could be found.

For the Greek refugees the League has done still more. Through its machinery a loan of £12,000,000 for their settlement in agricultural and other employment was obtained, and under the international control of a League commission this settlement has been carried out with remarkable success. On June 12, 1926, the Council of the League of Nations announced their intention of recommending a loan of £2,250,000 to the Bulgarian Government to assist the settlement of the Bulgar refugees. The conditions for administration and security were similar to those laid down in the case of the Greek refugee loan.



For the Armenians the same passport privileges and legal protection were obtained through the machinery of the League as had previously been obtained for the Russians. Their dispersal from places where they were concentrated in too great numbers, for example, from Greece, was also assisted by the agents of the League. This assistance took the form of an appeal for funds for the establishment of a national home in the Caucasus, and of the creation in co-operation with the mandatory Power and the International Labour Office of a series of agricultural colonies and urban settlements in Syria to relieve the congestion of the refugee

camps in Beirut, Alexandretta and Aleppo.

The effect of this League of Nations action is likely to be cumulative, and considerable as are its short period results in mitigating the sufferings of the refugees and in helping to solve the economic problems caused to the Governments concerned, its long period results are likely to be more important still. By the various kinds of action which it has undertaken, the League has helped to remove centres of disaffection and discontent; it has helped to build up the prosperity of different portions of the world; and it has helped to raise, by the distribution and settlement of industrious and highly educated refugees, the standards of civilization in various portions of the globe. It is, therefore, possible to say that, as the result of the generosity of a number of Governments and of their enlightened co-operation through the machinery of the League, the ultimate results of the refugee movements will be better than even the most optimistic could have ventured to expect.

REFUSE DISPOSAL, the general term employed in the United States to denote the solid wastes of a community, including garbage, rubbish, ashes and miscellaneous wastes. (For British practice *see* DESTRUCTORS.) Garbage may be defined as the waste matter resulting from the preparation, cooking and consumption of food. Rubbish is the miscellaneous material discarded by a community as being no longer of use or value. It includes paper, rags, old clothing, broken furniture and numerous other articles. The term ashes, as generally used, refers only to the residue resulting from the operation of heating plants in homes and small business establishments or offices. In the average city (there are wide differences in various cities) of the United States, garbage comprises about 13% by weight and 18% by volume of all refuse; rubbish amounts to only 7% by weight, but to 25% by volume; ashes form approximately 80% by weight and 57% by volume of the total. Garbage weighs from 1,000 to 1,200 lb. per cubic yard, the weight varying with the season, temperature, rainfall and other factors. Of the total weight of garbage, from 60 to 65% is moisture while the combustible matter amounts to 15 or 20%. A pound of dry garbage contains about 8,500 heat units and about 60 lb. of grease per ton can be extracted from raw garbage. Rubbish differs from garbage, which is unstable and subject to rapid decomposition, in that it breaks down slowly and relatively without objection; it has considerable fuel value, the volatile matter ranging from 40 to 70% of the total. Ashes collected from residences and small business establishments also have some fuel value.

The heavy line indicates the loads of ashes removed, light line, the loads of garbage removed

Quantity of Waste.—Where the collection service is good, the average daily amount of garbage collected ranges from 0·5 to 0·75 lb. per person. The amount of garbage appears to be increasing, and data collected from a number of cities where careful and reliable records have been kept showed that in 1927 the average production was over 200 lb. per person per year, compared to previous figures ranging from 150 to 175 pounds. The daily production varies somewhat with the season. In the Southern States, watermelon rinds form a large part of the garbage during the late summer months. The amount of rubbish collected ranges from 50 to 175 lb. per person per year, averaging about 75 pounds. The collections of rubbish remain fairly uniform throughout the year, increasing slightly during the spring and fall months. Ashes, in the Northern cities, compose a large part of the refuse collected, but where climatic conditions are milder, the amount may become unimportant. Street sweepings, night soil, manure, dead animals and other wastes vary in amount according to local conditions and local regulations governing their collection. However, the collection and disposal of these wastes are not, in most cities, functions of the general refuse collection organization, but are performed by special departments. Therefore, they will not be considered here. The total amount of refuse collected per person per year ordinarily amounts to 1,200 to 1,700 lb. but because of the many factors influencing collection, the amounts reported by typical cities range from 800 to 2,500 pounds.

Collection of Wastes.—The collection of waste is generally considered to include both the actual gathering of the garbage, rubbish and ashes, and their subsequent transportation to the point of disposal. The methods of collection vary; in *separate* collection, garbage is collected separately and apart from the other wastes which may or may not be collected together; in *mixed* collection, garbage, rubbish and ashes are collected at one time and from one receptacle. Separate collection of garbage is the general practice in the United States. A survey of 190 representative cities showed that garbage was collected separately from ashes and rubbish in 139 of them, while 51 cities collected mixed refuse. The practice of separate collection is based upon either utilization of the garbage, as in feeding to swine or reduction, or on cheaper disposal of the less objectionable components of the wastes. In many cities, rubbish and ashes, which comprise the great bulk of the refuse, may be dumped or used for filling within the city limits, while garbage disposal must be accomplished at some distant point. In such cases, the saving in hauling and handling costs may be much more than the extra cost occasioned by separate collection.

Where garbage is collected separately, it is the usual practice to collect it three times a week in the summer and twice a week in the winter, though nearly 20% of the cities make daily collections of garbage in the summer. Mixed refuse may be collected less frequently and at longer intervals because decomposition is slower and the usual practice is to make two collections a week. Ashes and rubbish are collected weekly or at longer intervals. Most of the large cities collect refuse by municipal employees.

Satisfactory collection and handling of refuse is impossible without proper receptacles for the storage of waste materials, and most cities have regulations covering the size, material of con-

struction and quality of garbage receptacles. They are usually required to be watertight, of impervious materials and to have a tight cover. The usual capacity is 9 to 15 gallons. Few cities require any special receptacle for rubbish or ashes, but generally provide that the former be tied in bundles, or placed in boxes or barrels; ashes should be placed in non-combustible, covered containers. Receptacles may be placed at the back door, at the alley

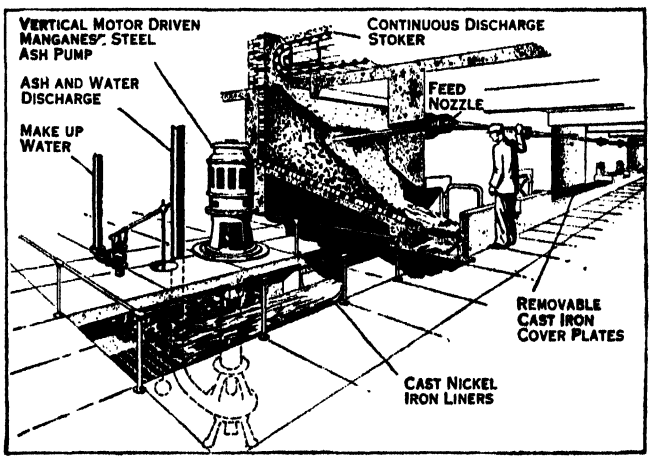
line or at the curb line. It costs more to collect from the back door, but it is the usual practice in the United States. Reports from 190 cities showed that 115 collected from the back door, 51 from the curb and 24 from either place.

Collection Equipment.—The employment of motor trucks in refuse collection is increasing and about one-half of the cities of the United States use motor equipment, though on house-to-house work in residential sections, where the amount collected from each house is small, horse-drawn equipment may operate more cheaply. For garbage collection, the 2-yd. body mounted on a 1 or 1½-ton chassis is probably the most popular, though larger bodies mounted on 2 and 3-ton chassis are used in many places. In ash and refuse collection 3- to 5-ton trucks are more economical.

Disposal.—Many methods of refuse disposal are in use in the United States, probably due to the differing conditions existing. The methods in use include dumping on land and in water, filling, ploughing under, burial, feeding to hogs, incineration, reduction, sorting and utilization. Garbage from cities is relatively rich in food values. If these values can be reclaimed, the net cost of disposal may be reduced. In addition to the food value of the garbage, the facilities for the cheap and ready disposal of rubbish and

BY COURTESY OF THE CITY OF N.Y. DEPT. OF STREET CLEANING



LOADING GARBAGE WHICH CANNOT BE BURNED ON SCOWS TO BE TAKEN 20 MILES OUT IN THE OCEAN AND DUMPED

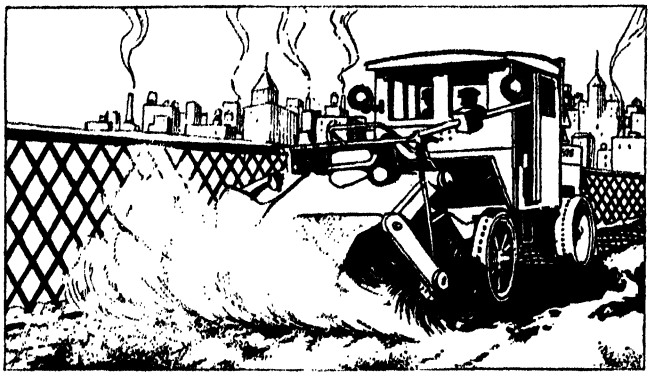
ashes and the availability of easily accessible sites for incinerators will be factors in the choice of the method to be used.

Disposal of refuse by filling low places and reclaiming marshes and swamp lands is quite common among the smaller cities; in larger places sites for dumps are rarely available except at a considerable distance, and the longer haul thus necessitated increases the cost. Garbage cannot be dumped satisfactorily, unless extreme precautions are taken, and disposal in this manner is rare, except in cases of emergency. For satisfactory disposal by dumping, garbage must be treated with a deodorant or disinfectant, spread out in thin layers, and covered immediately with earth, ashes or other inorganic material. Ashes make good filling material and are used in many cities for making fills. Rubbish is frequently dumped, but because of the time required for the fill to compact, and the miscellaneous material composing rubbish, it is not as generally satisfactory. Dumps are almost certain to catch fire, resulting in objectionable fumes. To obviate this, many cities burn the combustible matter as it comes to the dump. Paper is usually collected, baled and sold. Picking over the materials on the dump is quite a general custom and usually affords the city some revenue.

Sorting.—While in most cities, sorting is done mainly on the dumps, as previously mentioned, a more systematic procedure is employed in a number of places. A belt conveyor, upon which the refuse is dumped, and beside which a number of pickers stand, is the usual arrangement. Each picker takes from the moving belt one or more types of material from the refuse. Among the more valuable materials salvaged are paper, glass, bottles, metals, rags and tin cans. While the revenue from this work is frequently considerable, few cities have found it to be sufficient to pay for the labour and overhead of the plant.

Burial.—Few cities dispose of their garbage by burial. In case of the breakdown of other methods of disposal, burial is sometimes employed as a temporary measure. The usual practice is to place the garbage in trenches about 2 ft. deep and 4 to 6 ft. wide, the garbage being deposited in layers from 12 to 18 in. deep. Before covering, the garbage should be sprayed liberally with disinfectant

BY COURTESY OF THE ALLEN SHERMAN HOFF CO.



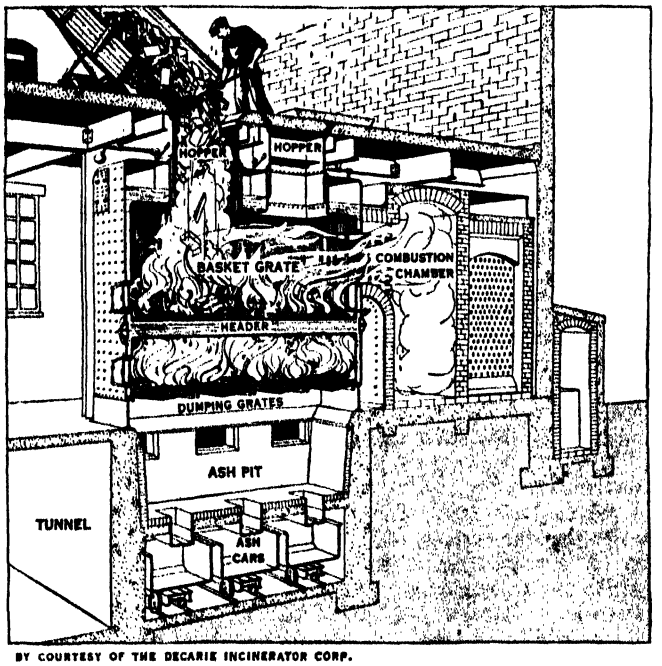
HYDRO JET SYSTEM OF REFUSE DISPOSAL, SHOWING VARIOUS PARTS

or crude oil. A cover of 12 to 18 in. of earth appears to give best results. For winter disposal, the trenches must be dug before the ground freezes, and covering can be done in early spring. Sandy, well-drained soil is most suitable, and where conditions are favourable, the land can be reused in 3 to 5 years. Ploughing under of garbage is a little used method. The cover secured is very thin, and men with hoes must follow the plough to cover particles not turned under.

Feeding to Swine.—The U.S. Department of Agriculture estimates that the garbage of more than 8,000,000 people is fed to hogs. A survey of 200 cities by *Public Works* showed that 39% of them fed all or part of their garbage to hogs. It is estimated that 50 lb. of garbage will produce 1 lb. of pork. Based on a live market price of 10 cents a pound for pork, garbage is therefore worth $4 per ton, from which must be deducted the costs of labour and hauling, interest and depreciation on equipment, and other items. While some of the food value in the garbage is utilized, in very few cases is the return sufficient to pay for both collection and disposal, though the revenue received may reduce materially these costs.

For utilization of the garbage by hog feeding, frequent collection is necessary. In the summer, collections should be made at least three times a week. Careful separation of the garbage is necessary, since its value as a food depends upon the care with which rubbish, glass, crockery, soap and other harmful materials are excluded. It is always difficult to find a suitable situation for a

farm, as there is always objection to its establishment in settled areas; as a result an isolated place usually must be chosen, with a resultant long and costly haul. Dry and well-drained sites, preferably with sandy or gravelled soil, and with plenty of water, are almost a necessity. Hogs should be fed on platforms, which should be of impervious materials, and so arranged as to reduce spillage and waste. The refuse remaining from the feeding, which,



BY COURTESY OF THE CITY OF N.Y. DEPT. OF STREET CLEANING

A SWEEPER AT WORK CLEANING THE WILLIAMSBURG BRIDGE OF SNOW

with the droppings from the pigs, amounts to 40 to 50% of the original volume of the garbage, must be removed daily. Disposal of this waste is difficult; composting, burial and incineration have been used in various places with some success. Cooking of the garbage is not desirable, as the hogs are less able to choose the materials most suited to them. Hogs fed on garbage are liable to suffer from cholera, and immunization is necessary to prevent loss.

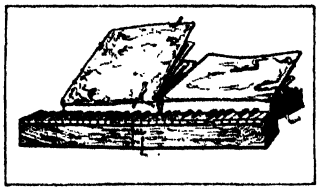
Incineration.—The complete destruction by fire of all wastes in specially constructed furnaces called incinerators has several advantages. It permits the collection of mixed refuse, thereby

BY COURTESY OF THE DECARIE INCINERATOR CORP.

A SECTION OF A GARBAGE DESTRUCTOR SHOWING DIFFERENT PARTS

reducing the complexity and difficulty of the collection service; incinerators frequently can be situated near the centres of the largest sources of production of waste, thus reducing the length of haul and the cost; the possibility of having several plants placed at suitable locations throughout the city permits still greater reduction in haul and provides insurance against complete interruption of all disposal facilities. Some slight revenue is occasionally available from steam and from clinker, but this is unimportant. In the United States incineration is employed for the disposal of mixed refuse and of garbage alone. The mixed refuse will normally burn without added fuel, but when garbage is burned, some additional fuel must be supplied. When garbage alone, or very wet refuse is to be burned, a drying hearth is provided upon which the garbage or wet refuse is placed. The flames from the burning material on the grate pass over this material, drying it.

Either natural or forced draft may be employed in operation, but, unless the refuse is unusually heavy and compact, natural draft is sufficient, the air being supplied to the furnace pre-heated to a temperature of about 400° F. The furnace is commonly mechanically charged.



Both high and low temperature incinerators are used, local conditions usually dictating the choice of type. With the high temperature plants in which the interior of the furnace is maintained at 1,600 to 2,000° F, odours are effectively destroyed; low temperature plants operate at 1,250 to 1,400° F, which does not always prevent the emission of odours. The high temperature plant, therefore, is especially suited for use in closely built up sections where discharge of odours cannot be permitted. Low temperature plants do not emit odours at all times, but may do so when the fire is cooled below the safety point. In 1927 about 40 cities in the United States installed incinerators, and this method is increasing.

Reduction.—Some of the fats and food values in garbage may be recovered by the reduction process. The products of reduction are grease and tankage. The grease, which is of low grade, is used in making soap, candles and similar products, while tankage forms a base or filler for fertilizer. Reduction is applicable only to garbage and dead animals, and other wastes must be collected and disposed of separately. Because of the costly and complicated equipment required for this process, the necessity for skilled operation, and the large overhead costs, reduction is not commercially feasible for cities having a population less than about 100,000.

There are two general processes of reduction, the *drying method* and the *cooking method.* Though the latter process is higher in first cost and operating cost, more grease is recovered and the by-products are in somewhat better condition. The yield of grease ranges from 2 to 3% of the original weight of the garbage, while from 150 to 225 lb. of tankage per ton are produced. The value of the grease varies with the market; tankage value is determined by its content of ammonia, potash and bone phosphate of lime, which carry the same values as in commercial fertilizers. To be commercially saleable, tankage must not contain more than 10% of moisture.

In the cooking method, the garbage is cooked in digester tanks for five or six hours, and then pressed. The grease that rises to the top is skimmed off and the solid matter dried and percolated with a solvent to remove the remaining grease. In the drying process, the garbage is crushed or ground and passed through driers, then being percolated to remove the grease. Odours are troublesome in both methods, but are perhaps less difficult to control in the cooking method. Washing with a fine spray of water, burning and treating with chlorine gas are among the methods employed to destroy odours, but none of these has been fully effective. Care and cleanliness in operation are important factors.

Solid and liquid wastes also result from these processes. The former consist largely of the rubbish sorted from the garbage, and are usually buried or burned. The liquid wastes include floor washings, waste liquors and drainings. They may be discharged into the sewer system or treated in an individual plant. Because of the likelihood of odours, reduction plants, like hog farms, must be situated in thinly settled areas, usually far from the city limits. This requirement of situation necessitates long hauls, which often materially increase the cost of disposal. (W. Ha.)

BIBLE REGAL, A SMALL PORTABLE ORGAN WHICH FOLDS UP LIKE A BOOK

REGAL, a small late-mediaeval portable organ, furnished with beating-reeds and having two bellows like a positive organ; also in Germany the name given to the reed-stops (beating-reeds) of a large organ, and more especially the "vox humana" stop. During the 16th and 17th cen-

turies the regal was a very great favourite, and although, owing to the civil wars and the ravages of time, very few specimens now remain, the instruments are often mentioned in old wills and inventories.

REGALIA: *see* JEWELS, CROWN; CORONATION.

REGENCE STYLE, in architecture and the decorative arts, a name sometimes given to a style transitional between the classic grandeur of the Louis XIV. work and the freely imaginative rococo of the developed Louis XV. period; so called from the fact that from 1715 to 1723 France was under the regency of Philip, duke of Orleans. (*See* LOUIS STYLES.)

REGENERATION IN ANIMALS. Like every substance, the tissues of our body are subject to wear and tear. They would soon be useless if there were no possibility of repair. The skin would rub off, the nails grind down, the hair split and fall, the muscles and nerves be worn out by fatigue. As it is, these tissues are incessantly growing but in such unobtrusive ways that we do not think much about the matter and take this physiological regeneration for granted, without inquiring into its causes. It is only in certain cases, when our skin peels off in sheets or when we trim our hair after the fashion and cut our nails, not worn enough by contact, that we become aware of this growth. In some animals the skin is periodically shed in one piece. In such creatures, for instance crayfish and snakes, growth of the whole body continues as long as these moults or ecdyses occur. Here the connection between physiological repair and growth is distinctly seen. Not only the damage done to our body by use, but also accidental injuries are made good by natural means. If we cut our finger, it will soon heal, the damaged cells being replaced by new ones. Torn-off nails may also regrow, an example of accidental regeneration in man, which exceeds mere wound healing. The loss of a whole limb, on the other hand, is irreparable by regeneration in human beings but not in other animal types. If a newt loses a leg or tail it will grow again. Even heads can be regenerated by some creatures, which are able to survive the accidental loss of the anterior part of their bodies.

Popular Belief.—Long before modern times the possibility of cut-off parts being regenerated fascinated the imagination of mankind. In Greek mythology the Hydra serpent, eventually slain by Hercules, was supposed to be able to grow two heads instead of each one cut off. Possibly this myth is founded upon the fact that not infrequently two-headed snakes are found in nature. Now, although snakes are neither able to survive the severing of the head from the trunk nor to regenerate it, the hypothesis is well substantiated that these monstrosities owe their origin to a process of splitting and regeneration in the embryo. Be this as it may, the name of the mythological serpent "Hydra" was later given to certain freshwater animalcules, when they were detected in the time of the first microscopes. The plant-like aspect of these hydras suggested experiments on multiplying them from cuttings much as gardeners do with certain plants. These animals behaved like plants, each piece growing into a perfect specimen. Moreover, when split at the anterior end they proved true to their name and regenerated two heads from one piece. The occurrence of accidental regeneration was in some cases well known in ancient Greece. The *Sauroktonos* represents a youth in the characteristic position occupied by boys in Greece and Italy even to-day, when trying to catch lizards with a grass noose. This statue shows that from olden times the ways of lizards were known to their persecutors, and the easy breakage of the lizard's tail and regenerating individuals with tails in different stages of repair must have been observed. More than two centuries ago a scientist travelling in Portugal recorded that many lizards lose their tails in this way and suggested that the not infrequent duplicities and triplicities of tails in that country might be of regenerative origin, due to complicated wounds; a suggestion since verified by various experiments. Popular belief in the regenerative powers of the indigenous animals has not always proved reliable. In some parts of Italy the custom of eating the hind legs of frogs has led to the barbarous procedure of removing the legs from the living animals and returning the latter to the pond on the assumption that the legs will be regenerated. This erroneous idea seems to have arisen from the occasional observation of frogs with much smaller hind feet than usual. But extensive experimental work has shown that such individuals only arise when the legs are removed in the tadpole; legs removed after metamorphosis are never replaced. Another fallacy is the belief of Spanish fishermen that male fiddler-crabs robbed of the big claw they carry on one side grow a small one in its place, while the one on the other side enlarges correspondingly. In reality, the big claw, if lost, is replaced as such, the small one not changing its character. We shall see later on that in other Crustacea such transposition of chelae really occurs but only in special circumstances. Before experimental methods were applied, biological science made the same mistake in the case of the lobster, transposition of the chelae being inferred to occur in the adult on account of stages found in nature showing a different degree of development in the claws. But recent experiment has proved that such reversal only occurs after removal of a claw in young stages: operations on the adult lead to a direct regeneration of the type of chela removed. Although the regeneration of claws in crustaceans was known to the ancient philosophers, experimental evidence was not obtained before the above-mentioned researches on microscopical animals led to methodical experiments with larger forms.

Theory of Selection.—Positive evidence of the regeneration of parts easily lost and therefore often found in nature as miniature structures was obtained by simple experiment. Unfortunately, before extensive research in this direction had been carried out the interest of biologists passed to the theory of evolution. Starting with the idea that useful characters would be preserved by natural selection, it was held that all characters now observed in animals were due to this agency. It was cited, as proof of this thesis, that species much exposed to the attacks of enemies and easily injured readily regenerated lost parts. Some authors tried to establish that regeneration was restricted to these cases. They observed that birds with beaks liable to get injured in use, *e.g.*, parrots and woodpeckers in pecking hard material, storks and fighting-cocks in their mating combats, were able to regenerate the injured beak. On the other hand, from a single instance of an old goose which was not able to restore the broken-off tip of its bill, it was rashly inferred that beaks like those of water-fowl, used only for handling soft substances, lacked the power of regeneration. This conclusion has not been borne out by subsequent experiments on young geese and ducks, which can regenerate the proper form of the bill when the tip is cut off. It has further been shown that homologous parts of the jaw of lizards regenerate, although in contrast to the tail they are strongly fixed to the body and scarcely ever injured. Other instances of correlation between liability to injury and capacity of regeneration have been sought in amphibians. We have already mentioned that common newts are capable of regenerating their legs. This capacity has been ascribed to the intervention of their foes. Now in some caves certain blind forms of tailed amphibians are to be found without any rapacious animals being present which would be able to prey upon them. Although former experiments had shown that the power of regeneration is possessed by this cave-dwelling *Proteus*, their inability to restore lost members has been upheld on the plea that they are not found in nature with regenerated legs or tails. But repetition of the experiments has proved their validity; and the reason for the absence of regenerates in nature is the low temperature of the caves and their proneness to infection, when the amputation has not been made under sterile conditions. If the theory of the acquisition of regenerative capacities by natural selection were correct, one would infer that rudimentary organs, whose regeneration would be of no value to their bearer, would have lost this potency. But here again the fact that hermit crabs regenerate their rudimentary abdominal legs contradicts the theory. Nevertheless, the fascination of this view is so strong that it repeatedly crops up and is tested anew. Whereas the external gills of newts are exposed to injury, the internal gills of frog-tadpoles are well protected; experiments have recently been carried out in expectation that they would prove devoid of regenerative capacity. The experimenter was disappointed by the

prompt restoration of the excised gill-filaments. Many organs being internal in all animals were supposed not to regenerate: the lungs, for instance. The first experiments on their excision in newts being negative, this has been taken as corroborative evidence. Later research on a larger scale has shown that partially extirpated lungs of salamanders and many other internal organs regenerate, provided that a small piece of the tissue is left in place. The continued discrepancy between facts and expectation made it necessary to look for some other explanation of the distribution of regenerative faculties than natural selection.

Distribution.—For the last 30 years we have witnessed a vast accumulation of experimental evidence in biology and have at last obtained enough facts on regeneration and non-regeneration in animals for a general summary. Beginning with the simplest forms, the protozoans, representing a single cell of protoplasm including one or more nuclei, we find them capable of restoring their form not only after their anterior or posterior half has been cut off, but also when they are cut into small pieces, the only condition being that each piece contains a bit of nucleus. Proceeding to the multicellular types the hydras are able to develop new individuals from cuttings, and many of the coelenterates, the group to which the hydras belong, behave in this way. Nevertheless, there are certain restrictions as to the parts that are able to restore the animal as a whole. Passing this by for the moment, the next two groups in the scale of the animal world, the echinoderms and the worms, comprise species still capable of multiplication by fission, the several parts completing themselves by regeneration. As examples, the starfish *Linkia,* which regenerates from a piece of one arm, and the freshwater worms *Lubriculus*, *Nais* and *Stenostomum* may be cited. Many of the ascidians, too, are capable of complete regeneration. All other types show a great restriction in this regard, yet in the molluscs, arthropods and lower vertebrates the appendages and sense-organs can as a rule be restored, if not lost at a late stage in life. Thus the arms of squids, the eye-bearing tentacles of snails, the legs of spiders, all the appendages of crustacea and insects and the limbs of fish and amphibians grow again after injury. In the reptiles, further restrictions occur, the regeneration of the tail and jaw being the only ones of importance. Broken-off legs are never replaced by new ones, although examples have been found in nature with a tail-like appendage arising from the stump of a leg. In warm-blooded vertebrates amputated tails or limbs are incapable of producing more than a short conical projection. The most achieved in the way of remodelling in mammals has been found in the tail of rodents, *e.g.*, dormice, the broken vertebra growing to form a tip which by a tuft of hair simulates the normal tail-end. From this brief summary three conclusions can be drawn: first that with ascent in the scale of animal types, regenerative capacities are more and more curtailed; secondly, that regeneration is an original and general faculty of living matter, becoming lost by secondary complications in the course of evolution; and thirdly that natural selection has been impotent even to maintain the power of restoring lost parts shown by low types. Therefore, correlation of regenerative faculty with the probability of loss or the survival of the fittest must prove futile. Would not the possibility of replacing lost legs be of as much value to birds and mammals as to crustaceans and newts? Can we conjecture why regeneration has been thrown overboard in the highest classes of animals? For answer, we must turn to the conditions under which the replacement of losses is possible in genera more or less gifted in this respect. The mode of growth or physiological regeneration varies in different creatures. Some types, on periodically shedding their skin, replace not only this outward covering but renew all the internal tissues too, with the exception of some cells which have lost the power to divide. Others, on the contrary, retain the great bulk of old tissue, as many of these have undergone a transformation inhibiting their further reproduction. Crustaceans, spiders and insects belong to the first, amphibians and reptiles to the second group. The former escape from the old shell or skin in a limp condition; the latter keep the skeleton, tendons and other internal parts through their moult. The higher the grade of ossification the more stable the system remains and the less it is wont to undergo renewal in physiological regeneration. Now the power of accidental regeneration wanes with increasing ossification, indicating once more its correlation with the physiological processes of growth. There appears thus to be an advantage for the rigidity of the body to be maintained through the moults even at the cost of losing the regenerative power by the incorporation of stable elements. We know, indeed, the time of moulting to be a critical one. Even the mere change of skin in the cold-blooded vertebrates and the moult of feathers in the birds is of much inconvenience, these animals being then much more sensitive to external factors. It is therefore reasonable to suppose that in mammals the method of continuous repair has been evolved to avoid the disadvantage of moulting and that the nearly total loss of regenerative power has been the price. It may also have been of advantage to warm-blooded animals to economize growth material by not changing it completely at short intervals. as they expend energy not only in their movements and growth, but also in the maintenance of their body-heat.

Memory.—Another great advantage, the most far-reaching of all, has been gained by the stabilization of the nervous ganglionic cells, which cease to divide in the mammalian brain comparatively soon after birth, thus guaranteeing a stable substratum for the preservation of memory. In several instances we have been able to prove this by experiment. Infusorians fed with carmine refuse to take the grains of this substance after a short time. But as soon as the animal has split into two new cells, this memory is lost, carmine again being taken. Certain predatory grasshoppers may be taught to take food at a selected place of their cage, but between two moults they forget what they have learnt before, probably because some ganglion-cells are renewed, as seen by histological examination. The same behaviour has been observed in amphibian larvae, when they metamorphose. This raises the question as to what influence age and stage of development may have on regeneration. If our assumption be correct, that accidental regeneration is directly connected with physiological regeneration and growth, we should expect most regeneration at those stages during which physiological processes and increase of size are at their height.

Age and Size.—The rapidity of substantial change and growth decreasing with age, young animals ought to regenerate better than old ones. This conclusion is borne out by all the facts and experiments at our disposal, as long as the removed parts are strictly comparable. From this general statement it follows that higher organisms devoid of a certain faculty to restore parts of their body in a developed state may possess this faculty in their youth. The frog is unable to replace a limb, whereas it is able to regenerate the same member as a young tadpole. The most striking example of this kind is offered by the insects, which never regenerate limbs as imagos, but do so as long as they are in the larval state. Here, with the last moult to the definitive form, growth ceases. Examples have been brought forward in which seemingly the young stages show less regenerative capacity than older ones. If the tailed larva of the tunicates be cut in two, regeneration will not take place in both pieces, whereas the metamorphosed animal may be cut in two and regenerate from both pieces. But then the cut passing transversely through the middle does not separate homologous halves in larva and imago. Again, in the starfish the developed creature restores all missing parts when cut in two, whilst the pluteus stage is incapable of regrowing its skeletal arms. Here, too, there is no homology whatsoever between the so-called pluteus arms and the rays of the developed starfish. These latter arise from a new rudiment at one side of the larva during metamorphosis. Since it is difficult to compare the regenerative capacity of larval and imaginal stages, it is necessary to restrict our research to such periods of animal life, during which growth is yet proceeding, but no change in differentiation occurs, when seeking strictly comparable quantitative data of regeneration. Such material afforded by tadpoles, by newts in their larval or in their metamorphosed state, and by crustaceans, has been treated statistically as to the increments of size in the regenerating tails, legs and claws respectively in equal periods. The increase in the size of the regenerating member is first only

small, rising in time more and more, then again falling off and subsiding to the growth-rate of the normal member, as soon as the normal size has been attained by the regenerate. This rise and fall is mainly due to the increase of regenerating material, which multiplies from a small bud, but later on lessens its rate of multiplication. If we do not take the absolute mass that has been added to the miniature regenerating member, but calculate the coefficient by which we have to multiply the size at a given time to get its size at the next, this relative value is highest when the regenerating bud begins to differentiate, and falls off first quickly, then more slowly as time goes on. The curve of regeneration is inversely proportional to the time. We may picture growth as a stream losing energy as it flows on, but on the whole not showing a great fall from one point to the next. If, on the contrary, a part of the river-bed is dug out, so that its steepness is increased, the rapidity of flow will rise at the commencement of this section, then slow off and regain its natural rate, when it reaches a normal level. If this comparison is true, we must conclude that, everything else being equal, the rapidity of regeneration ought to be greater if the cutting has been done nearer to the body than if it has been carried out further towards the tip. Now this has been observed over and over again. Unacquainted with these statements, some authors have postulated a direct correlation between distance of cut surface from the regenerating body and the quickness of regeneration, on the plea that it would be easier for the animal to repair a small injury than a big one. But this latter thesis is not in accordance with experiment, for regeneration after the amputation of several limbs is not only as rapid as that of a single limb but actually proceeds even more rapidly. There is, of course, a limit above which regeneration slackens or ceases, when the injury has been so severe that the reserves of bodily growth are not able to fill the gaps. The explanation for the increasing velocity of regeneration with increasing losses may be found in the decrease of the mass which has to be continuously overhauled by physiological repair. The less the old parts require of this process, the more material will be available for newly growing structures. It is perhaps in this connection possible to account for some observations of increasing velocity of reconstruction with repetition of the same operation. The posterior end of the worm *Amphiglena* is provided with branched gills. If these are cut off, new ones make their appearance. If these in turn are removed, they will be replaced in a shorter time, and so on, more quickly every time they have been lost. As the old tissue at the cut surface is also remoulded, less of this work will have to be done when the succeeding cuts pass through more and more rejuvenated tissue.

Function.—But there is yet another way of looking at these facts. What influence has function on morphological repair? In certain cases there is little doubt of the positive influence function may have on the quicker attainment of the normal form. When the tail of a newt is cut off by an oblique operation a bud will first grow at right angles to the cut surface, thus giving a crooked appearance. This abnormality will be adjusted quicker if the newt is allowed to swim about actively, than otherwise. The tentacles of digging forms of actinians are, after loss, not regenerated in their whole length if the animals are prevented from burrowing. In these cases it is clear that function modifies the muscles in the same way as it does during every exertion. On the other hand, the first stages of regenerating organs are often incapable of functioning. Antennae, claws and legs of crustaceans are, as regrowing buds, inclosed in a chitinous sack, thus being prevented from moving or even receiving external stimulation. Nor does function apply, when the head of a flatworm has been removed and new eyes develop in a tissue that has not before acted as a light-receiving organ.

Nerves.—Although these facts seem to prove conclusively that function cannot create form, but only strengthen the growing part, we have yet to consider the possibility that the nerves connecting a new growth with their centres pass stimuli of differentiation as they do other commands to the periphery. It has been and is still held by some biologists that there are valid proofs of such a dependence of regenerating organs on a special nerve or ganglion which normally innervates the structure which has to be restored. The stalk-eyed crustaceans have a ganglionic swelling of the eye-nerve inside the stalk. If the stalk is removed or the ganglion extracted and the eye itself taken away, no regeneration of the eye will make its appearance in adult specimens, although these will go on moulting. In place of the eye a feeler-like structure begins to grow, developing into a form most like that of the first normal antenna. This can be interpreted as a formative influence exerted by the antennal nerve on the bud in the cases where connection is made between the antennal ganglionic centre and the feeler-like structure. But this is very rare; generally no such relation appears. Moreover, the nerve grows from the regenerating structure centripetally and the outgrowth could therefore only receive the stimulation of the antennal centre through nervous contact after completion of the feeler. In young stages eyes grow even after removal of the whole stalk, and here a formative stimulus could only be supposed to act in the same way as in older animals if we suppose the optic ganglion to regenerate first and then to transmit the determining influence distally. In short, a somewhat similar replacement of one organ by another in regeneration has been shown to depend on the removal of a particular joint including a sense organ: the antenna of the stick-insects reappears as such if it is removed distally to the second joint. But if this, too, bearing the so-called Johnston's organ, has been taken away, the regrowth will resemble the first leg of the animal. This will happen even in individuals operated on immediately after leaving the egg-shell. In other insects only late stages restore a foot-like structure in such cases, whereas larvae operated on early will restore the antenna itself after total extirpation. In mantids the foot-like structure can be identified as a leg of the first pair by the broad femur and toothed tibia as compared with the slender, smooth appearance of the other two pairs. Besides the optic ganglion in crustaceans and Johnston's organ in insects, other nervous structures seem to be necessary for the growth of specialized parts; some forms of Nemertine worms do not regenerate if the brain has been removed, some flatworms do not grow new eyes before the cephalic ganglion has been restored. But in closely related species or even races there is no such restriction to be observed. Many experiments have been conducted to ascertain the rôle played by the nervous system in the regrowth of the newt's limbs. It has now been conclusively proved that a special nerve-centre or nerve-path is not necessary, but that some sympathetic nerves must reach the cut surface before differentiation of the bud begins. By deviating such a nerve the growth of a limb can be induced even in wounds made near the hind-leg but not including it. When the same nerve is made to innervate a cut in the tail it will induce an additional tail to grow. This seems to prove that the nerve does not induce a special form which is, on the contrary, inherent in the different regions of the body. Could we not suppose that this same explanation covers the above-mentioned facts concerning invertebrate animals?

Autotomy.—Whereas function cannot well have given rise to regeneration, a body of facts points towards its having induced special adaptations on the part of its owners. Some appendages are easily broken, for instance the lizard's tail. This apparently serves as a means of escape. As the reptiles, to which lizards belong, are believed to descend from amphibia-like ancestors which do not, as far as we can tell, include forms with easily-lost tails, although they are sure to have regenerated their legs as the living amphibians do, the power of easy breakage must have been acquired during evolution. The rupture of the lizard's tail is effected at preformed planes in every single vertebra, not between vertebrae. It is governed by nervous impulse inducing violent contraction of muscles which constrict and snap the vertebra. The regenerating tail does not replace the lost part of this or any other vertebra, a continuous cartilaginous rod running through it. It may be added that regeneration can also take place if a part of this new tail without preformed planes of breakage is removed or the original tail is cut off between two vertebrae, another proof of the priority of the regenerative faculty and its independence of easy loss. Similar adaptations are also presented by the legs of crayfish and some insects. Generally a furrow runs

round the second joint and furnishes the same ability of snapping as the preformed plane of the lizard's tail. In both cases, on seizure near the distal end of the appendage being felt, the animal struggles to get away, and the pull together with the reflex action suffices to get rid of the encumbrance. The constriction of the wound serves at the same time to prevent bleeding and is therefore of use for retaining the resources of restoration; moreover, regeneration can begin earlier and proceed quicker and more regularly than from irregular profusely bleeding wounds. But, on the other hand, the mechanism of this *autotomy* (self-amputation) may close the wound so thoroughly by telescoping one joint into the other that no regenerating bud can pierce its way. Thus, in grasshoppers and crickets, the hind legs are easily lost but do not regenerate after autotomy, whereas the two front pair of legs regenerate though incapable of autotomy. But if the whole hind-leg, including the first two joints, be excised, thus obviating the telescopic action, a miniature appendage makes its appearance. This proves that the regenerative faculty of the hind-legs is not really lost. In the stick insect all three pairs of legs are adapted for autotomy and regenerate not only from the preformed snapping plane, but also distal or proximal to it. It seems possible to prevent regeneration, at least in the middle leg, by removing it through a plain vertical cut, which is quickly covered over by chitinous plates smothering the underlying tissue that could otherwise grow out into the bud of the leg. Thus regeneration is always primarily present, secondary adaptations either modifying or preventing it from taking place. Autotomy serves merely its first purpose of allowing the animal to escape its foe, but is unable to restore the lost member. The adaptation might thus appear to be not worth while, as the mutilated insect, permanently encumbered in its movements, would be at a disadvantage and unable to propagate the species. Some examples show that deposition of eggs may occur shortly after the mutilation, for instance when fully-developed grasshoppers have lost a hind leg. Regeneration cannot set in, as no insect regenerates members after its metamorphosis. For the purpose of propagation all that is necessary is escape from the instant peril. In some worms autotomy directly serves the purpose of disseminating the genital products. At certain times of the year millions of pieces from the Palolo worms rise to the surface of the southern Pacific and reproduce their kind. In certain squids, a specially adapted arm of the male, the so-called hectocotylus, is detached and carries the male products to their destination. Autotomy may also lead to asexual reproduction; thus in actinians, flatworms, starfish and annelid-worms pieces give rise to new animals by regeneration. Often rudiments of structures to be renewed in the posterior piece may be seen before severance from the anterior as in the fission of infusorians.

Gonads.—What becomes of the bodies of worms which have shed the segments bearing the reproductive cells or gonads? Formerly, the theory of Weismann was widely accepted, *i.e.*, that the body of the animal was only an excrescence of the germ-cell not capable of influencing the new generation of germ-cells, descending in direct lineage from a part of the old germ-cell set apart from the beginning of differentiation and alone able to reproduce whole new individuals. After loss of all gonads the animal should then not be able to produce new germ-cells or complete individuals. But experiments on various creatures have proved beyond doubt that new germ-cells may arise and that a part of the body may in certain cases regenerate segments with gonads after total removal of the whole region that bore them before. Thus in hydrozoans, cutting off the head region inclusive of the gonads will not prevent new ones from growing. Flatworms cut into small pieces not only remodel their form but replace the gonads too. The sea-cucumber extrudes its intestine, including the ovaries, when left in stale water; on regaining normal environment everything is regenerated. When the arms of starfish are cut off, the new bud will enclose new gonads too, which do not seem to originate from the old ones situated in the remaining intact arms. Some annulate worms will, after amputation of the anterior body-region carrying ovaries and testes, grow a few segments which bear these gonads of both sexes. Curiously enough, in these regenerated anterior segments gonads and accessory sexual organs are regenerated in excess of the normal number, those of both sexes frequently appearing in the same segment, although they normally should be located in different segments. *Ctenodrilus* and *Rhynchelmis* are examples of this kind, whereas European earthworms are not known to regenerate the reproductive region. The cause of this is not apparent, especially as an Indian species seems to possess this higher regenerative faculty. In the crustaceans we know of some special cases in which the gonad degenerates when the crab is infected by the parasite *Sacculina*. (*See* SEX.) When this latter is removed from an infected male spider-crab, *Inachus*, a new gonad regenerates, but of a hermaphrodite or female type, producing eggs. In hermit crabs, *Eupagurus*, this transformation appears even without removal of the parasite. Artificial castration has not succeeded in crustaceans. No appearance of new gonads has been observed in insects. The primordial germ-cells may be sucked off from the eggs of Chrysomelid beetles in early stages, as they are then protruding at the posterior end of the embryo. Even after such an early operation as this the beetles remain sterile for life. The same has been observed in crickets, castrated as young larvae, and butterflies, the young caterpillars of which have been similarly treated. In molluscs only regeneration of the hectocotylus arm (*see* above) seems to have been observed, and here the germ-cells are carried into it from the gonad, which is not affected by the shedding of the arm. Some tunicates regrow from very small pieces, becoming sexually ripe in absence of their former reproductive glands, *e.g.*, *Clavellina*. Only a short while ago the vertebrates were thought totally incapable of replacing lost gonads. Castration and spaying has been practised so widely in many of our domestic animals and birds without fertility ever having appeared that it was held quite safe to perform experiments on the influence of a foster mother on the characteristics of the young by implantation of an alien ovary. Only when results after such transplantations in hens appeared, which, in contradiction to all other cases, seemed to prove an influence of the foster mother on the colour of her stepchildren, the suspicion arose that these chickens had, after all, been derived from eggs of her own. New tests revealed the fact that in these experiments new germ-cells had arisen from the host's tissue. But as the possibility could not be excluded that some part of the gonad had not really been totally eradicated by the operation, this alternative to the regeneration of an ovary was still left open. A better material presented itself in the mouse, the ovary of which is enclosed with the tube of the uterus in a pouch. Here the removal of the ovary is complete, if the whole pouch is taken away. It was a surprise to most biologists that experiments of this kind yielded positive results, putting the feasibility of the regeneration of ovaries even in mammals beyond doubt.

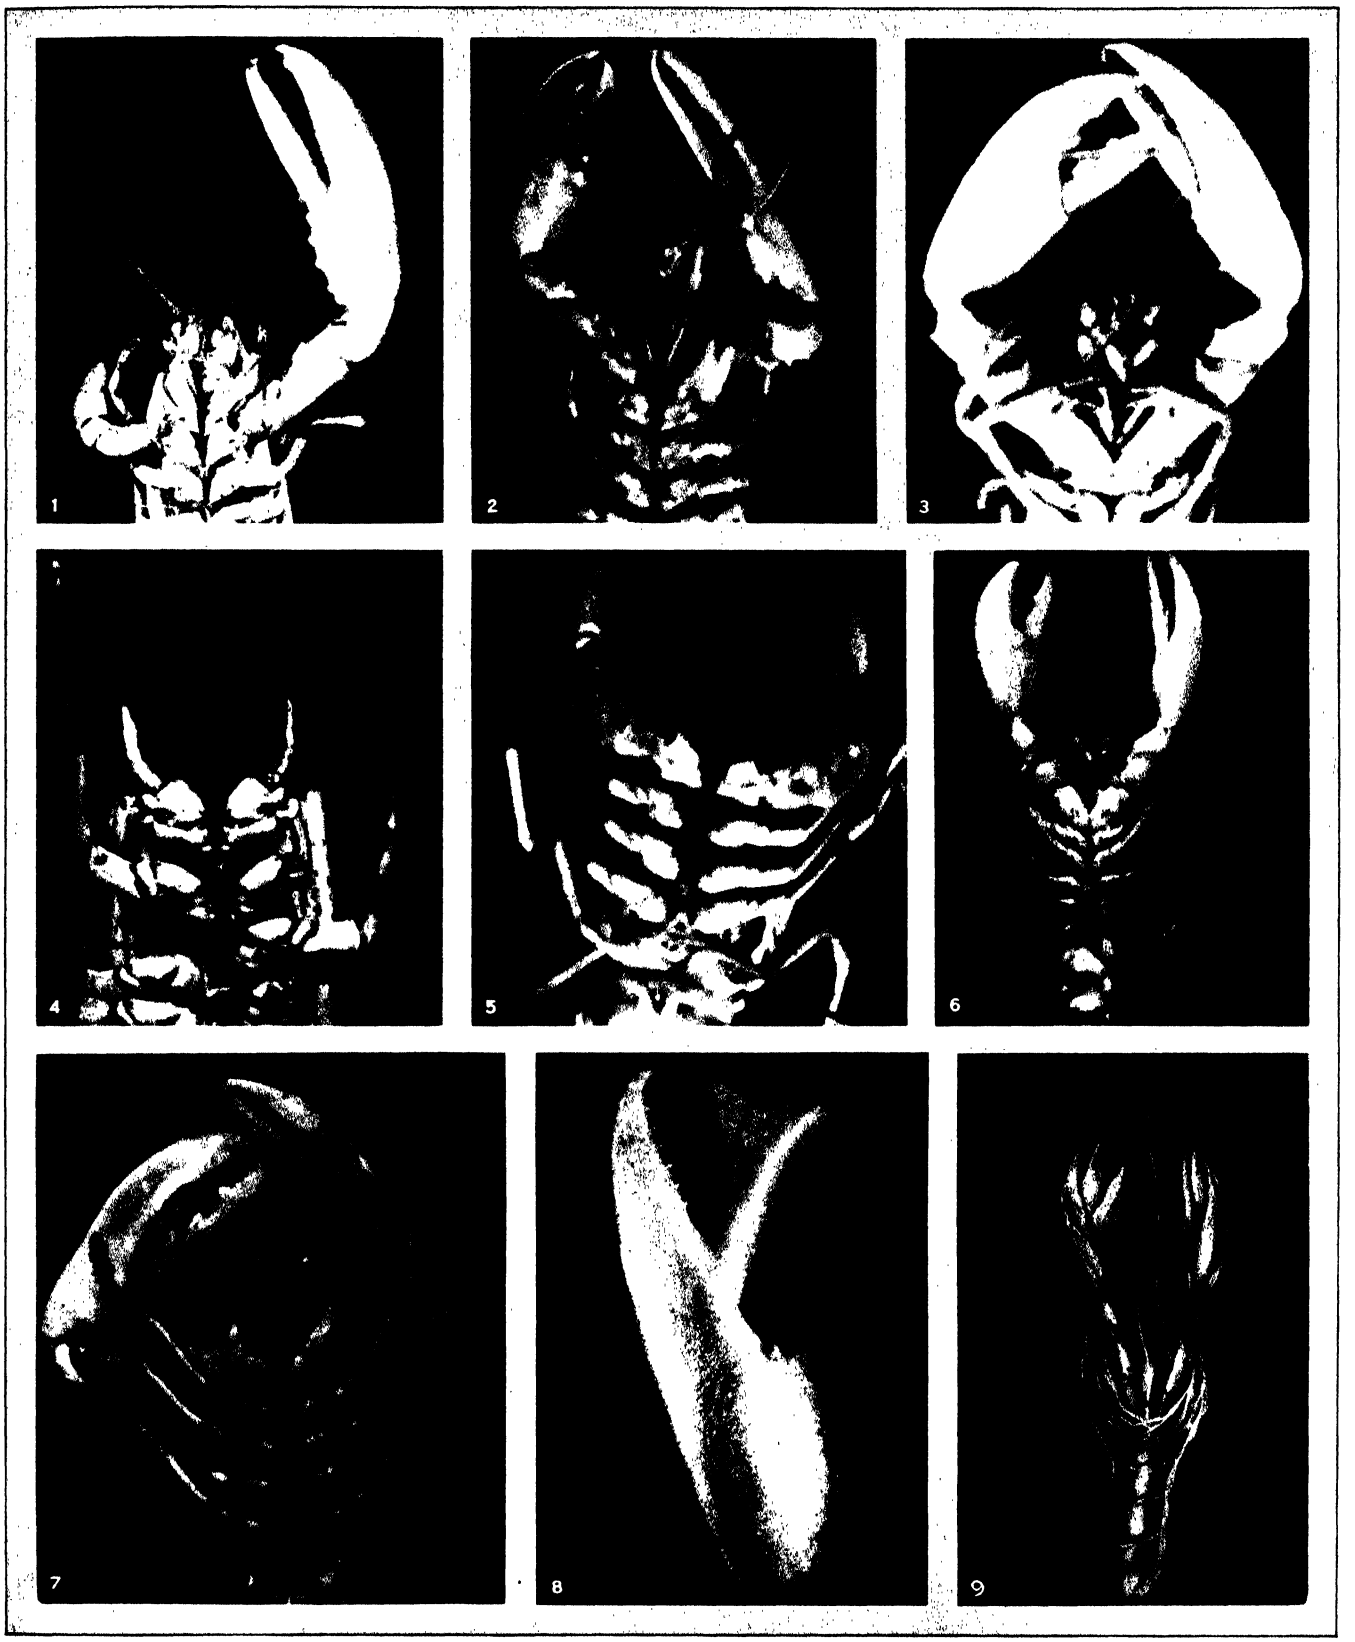
Morphallaxis.—Whereas germ-cells are the only ones in the higher classes of animals to reproduce the whole form anew, low forms are able to restore themselves entirely from small fragments. Protista may regenerate from parts 1-64th or less of their normal bulk, freshwater worms from a piece 500 times smaller than the whole body. But the reproductive cells are in many cases even less in volume compared with the entire animal. In many of the small pieces organs for ingesting food are altogether lacking, so that the restoration of form must proceed without receiving nourishment from the exterior. When the resources of the body are too small, it will not be possible for the animal to mobilize enough substance for growing regeneration buds at all the cut surfaces. Then the old tissue is remodelled to form most of the new body, which is laid down on a reduced scale in normal proportions. This phenomenon has been termed morphallaxis. It has been mostly studied in flatworms which afford a good opportunity for the gradual reappearance of the normal proportions and the shifting of structures from a peripheral position in the cut piece towards its normal place in the remodelled worm. The eyes and the pharynx are especially noticeable. In one kind of planarian a row of small eyes runs along the anterior margin not extending backward beyond the pharynx. When a piece of this animal, including the marginal eyes, has been cut off, the posterior eyes degenerate, thus ridding this part of its differentiation and making

room for the pharynx and tail to develop.

Cell-size and Number.—The size of the single cells does not vary much with the size of the planarian. In regeneration and morphallaxis the size of cells is retained too. Thus the flatworm remodelled on a small scale is not composed of smaller cells in the same number as before, but of fewer cells. We see how the different organs from the old piece have to be overhauled that they may be composed of fewer cells, if the proportionate number in the various structures is to be regained. In other animals, for instance the rotifers, the number of cells remains constant after the embryo has hatched. Here regeneration can only set in, when a part of a cell is removed. Artificially, this has been achieved by cutting away some rays of the "wheel," from which the rotifers take their name. If, on the contrary, whole cells are killed or only the nucleus of a single cell, then the structure to which these cells ought to give rise will never develop. Where now do the cells come from which in planarians, hydras, and other forms with great regenerative faculties are necessary to complete the individual? Several possibilities have to be taken into account. Either differentiated cells may undergo dedifferentiation, or those not yet differentiated migrate to the places of need; lastly, special cells may be in store for the purposes of restoring the lost parts. It is probable that all three methods are practised in nature, but by far the commonest method seems to be the one mentioned second of so-called interstitial or indifferent cells widely spread through the body offering a plastic material for every kind of regeneration. These cells are derived from layers of tissue which, since the development of the embryo, have not undergone any special alteration or served for other purposes than connecting different regions of the body. This raw material does not contain special rudiments for the organ it is to build up, but may be used at any point needed. Even the faculty to start the structure wanted does not reside in the undifferentiated cells; the regeneration bud must have its destination stamped on it by differentiated cells lying proximally to the cut surface. The proof of this fact has been given by the experiment of grafting regenerating buds to different parts of the body. When the buds are very young, taken shortly after regeneration has begun, they will differentiate not in relation to the place from which they were taken, but in relation to that where they are grafted. In a flatworm a bud taken from anywhere will form a head if it has been transplanted to the head-region, the regenerating bud of the hind-leg of a salamander grafted in place of an amputated fore-leg will grow into a fore-leg; even the tail-bud of a newt removed to a site near the fore-leg will grow out in the form of this leg. But all this is changed if buds a little older are taken as grafts. Then, be the bud attached to any place whatsoever, and it will yet give rise to the form it would have attained if left where it had originated.

Orientation.—Applying the technique of grafting to animals (*see* GRAFTING IN ANIMALS) it has been possible to test experimentally whether a structure already determined to form a special organ can be influenced by the place to which it has been transplanted, in regard to its orientation. If regenerating limbs are simply left growing, nobody would expect them to be oriented differently from the original limb they are replacing, therefore no special interest attaches to the fact that the regenerates always are in accord with the whole animal in respect to their orientation. But when young regenerating buds were first grafted without their fate being known, the question arose if a regulation would set in to give the bud the proper orientation towards the host independently of the way in which it had been artificially oriented to the host's stump. The answer seemed to be in the affirmative, when it was found that not only the orientation but also the differentiation itself conformed to the place where the graft had been attached. Only when older buds yielded the result already mentioned, was the observation made that with the determination to form a special organ the orientation had also been stamped on them. When, for instance, an old regenerating bud is taken from a newt's limb it will develop a dorsal surface looking ventrally if it has been grafted upsidedown; such a limb will, of course, be of no use to its bearer. Any sort of oblique and twisted limb can thus be produced by transplanting at different angles of rotation. The direction of growth always remains restricted to the long axis which runs proximodistally along the member. It remains restricted, but it need not proceed in the original direction. If a bud, already determined as to the sort of differentiation it is to undergo, be taken from a regenerating limb, its tip be cut off and this new cut surface adapted to the stump of the host's limb, it is of course prevented from growing in the right direction by the contact of the stump. Its free surface now grows in an opposite direction and something occurs that could be taken for a regulation: the differentiation proceeds as if the body were dictating the wanted orientation. Yet this is only apparent. One need only to change the dorso-ventral orientation, together with the reversion of the bud, to find the lack of influence on the part of the body as a whole, for no regulation towards the normal position will assert itself regarding the limb's back and palm. Further insight is given by experiments in which regenerating buds are not severed at their base but amputated together with a portion of old tissue. In grafting, this latter tissue is fixed to the host-stump and regeneration always proceeds along the lines originally laid down by the orientation of the old portion of tissue. Not only does this apply to cases in which the regenerating bud was old at the time of grafting, but also to young buds. These must then be determined by the orientation inherent in the old tissue immediately adjoining the regenerating cells, no influence from the body of the host coming into play. Moreover, it is not necessary that any regenerating bud be present at the time of transplantation for the same result to appear. When a portion of a newt's limb is grafted in a reversed position, so that the originally distal cut surface becomes proximal, outgrowth of all distal joints of the member will occur at the free surface, which before the amputation had been in contact with the proximal part of the limb. Here again, since the superfluous leg is only orientated by the direction of its original outgrowth and free end, we see that there is no regulation exerted by the body itself. If we want then to arrive at an explanation of the phenomena in reversed grafts, it is necessary to take into account the faculties residing in the parts and set free, when opportunity arises, of growing in the opposite direction by the exposure of cut surfaces. Not all parts are able to keep living when they have been totally separated from the animal, so that in many cases it is necessary to resort to grafting for keeping the parts alive long enough to watch their behaviour in regeneration. In these cases it is often difficult to decide if a given result has been influenced by the host or if the graft has exclusively used its inherent faculties.

Heteromorphosis.—On the other hand, animals which may be cut into several parts transversely to the length of the body without dying, afford the opportunity of observing structures growing from cut surfaces in a reversed direction. Let a flatworm be cut into three pieces, the head-end with the eyes, the body to where it narrows in to the tail, and the tail. Then the middle piece will regenerate a head with eyes at its anterior, and a tail at its posterior cut surface. The head-piece will not regenerate a tail posteriorly but a second head will appear directed backwards. Similarly, the tail will grow no head anteriorly but develop a second tail. This example of the flatworm shows conclusively that the faculty of producing a structure opposite in direction to that of normal growth is inherent in the head-piece and in the tail-piece independently of the organism as a whole, for the latter is not present in the experiment. Similar results have been obtained with hydroids and also with annelid worms.



The regrowth of tissue, which does not exhibit the form of the missing part but substitutes another familiar form of the same species instead, is termed heteromorphic regeneration (*see* HETEROMORPHOSIS); reproduction of the opposite body-end is called axial heteromorphosis. When a transverse cut is made near the eyes of a flatworm without totally severing the head from the body, the latter may remain attached to the trunk by a small connection, the borders of the wound gaping. From each of its free surfaces a bud of regeneration will arise. The one from the anterior margin of the trunk will of course develop a head looking in the same direction as the old one. But the bud from the posterior margin of the head behaves as if it were arising from a

piece totally severed from the body, developing into a head pointing in the opposite direction to the other two. By taking a triangular piece out of the body-side near the eye, the tip of the triangle reaching in to the middle line, the two cuts will again try to produce heads. These will grow at right angles to the edges of the wound, but not having room enough they will impede each other in their development and more or less coalesce.

Triplicity.—We are now in a position to give a more satisfactory interpretation of monstrosities which consist of the triplication of parts and conform to Bateson's rule—viz., that the three components lie in the same plane, the middle one being the mirror-image of the other two. Such triplications have not only been found in lower animals but also in arthropods and vertebrates. Generally, they affect in these types not the long axis of the body but lateral appendages. Only in one instance, the tail of the lizard, the monstrosity is not rarely found in the form of a threefold ending of the long axis. Now we may remember that long ago these abnormal tails were ascribed to accident and in our days their regenerative origin has been proved by experiment. It is of course not possible to keep the lizard's tail alive by itself, but the orientation of the three tails in the monstrosities conforms so exactly to what would be expected, if a tail nearly broken off regenerated, one in a forward direction and a second one growing backward, that there can be no doubt of the analogy between the faculty of the tail in flatworms and lizards of producing axial heteromorphosis by themselves. Passing over to the lateral appendages, we find triplicity occurring most often in animals with rigid external skeleton, such as crayfish and beetles, or with internal skeleton of hard bone, like frogs, birds and mammals. This correlation indicates the origin by breakage, because plastic, soft parts will easily join up again after having been wounded, whereas rigid structures will remain gaping when they have been broken, thereby giving opportunity for regrowth from the two lips of the wound. In several instances it has been possible to observe the two supplementary components arising in this way; triplicated horns have arisen after centrifuging the unicellular *Ceratium;* treble legs appear in lobster or praying mantis after appropriate injury; trefoil form has been induced in the newt's leg by preventing a cut from reuniting by insertion of a thread and in the arm of the sea-lily *Antedon* by a deep rupture. These observations all refer to animals and stages capable of regeneration. When specimens of frogs with a supernumerary pair of legs are found in nature, they cannot have arisen by regeneration of the frog after its metamorphosis because, as we have mentioned before, this stage is incapable of regrowing members. Here experiments on tadpoles had to be performed in their early stage, when the hind-legs were beginning to appear and they were still capable of regeneration. By an appropriate operation this rudiment was made to develop endings in two different directions, a pair of supernumerary legs, mirror-images of each other, being the result. There can scarcely be a doubt that triplications of a member in other animals incapable of regeneration in their developed state are also due to the severing of cells in the larval or embryonic stage. The fruit fly *Drosophila* has yielded a race in which not unfrequently treble legs appear in the imago. As the maggot has no legs that could break, this deformity must be ascribed to a weakness in the compound of cells developing into the imago's leg, which makes them fall apart, thus making multiple growth possible. In warm-blooded animals the artificial production of triplications has not yet been achieved. Nevertheless, all cases found in nature, to be seen at shows or in museums, conform exactly to Bateson's rule, so that we need not hesitate to see their cause in the rupture of embryonic tissues. In the last few years biologists have begun to make operations on embryos inside the maternal uterus, and will by this technique be able to decide at what stage a given mammal will be able to regenerate an arm or a leg. The few experiments so far conducted on rats indicate that this period lies relatively far before the day of birth. In fowls, the method of grafting pieces from early developmental stages to the chorio-alantoic membrane of the egg, has enabled us to see what becomes of these pieces nourished by the host's blood. This method will make it possible even in birds to test the faculty of embryonic limbs to produce terminal structures at both ends. Everybody is acquainted with the fact of our limbs being mirror-images of those on the other side of the body. It was therefore thought that when supernumerary pairs of legs are found in vertebrates they might represent a bud containing a leg of the left and one of the right side of the body. Apart from the improbability that a left and right member should arise without interposition of the vertebral column, we have been able to collect proofs of both supernumerary members belonging to the same body-side.

Reversal of Claws.—The clue was afforded by some crayfish, which normally possess claws of different size and form on the right and left side of the body. Instances of this heterochely occur in the pistol-crab *Alpheus,* the common lobster *Homarus,* the hermit-crab *Pagurus,* the shore-crab *Carcinus,* the swimming-crab *Portunus,* the fiddler-crab *Gelasimus* and others. When the large crushing shaped claw is removed from a pistol-crab the small cutting claw of the opposite side will, after one or two moults, assume the size and form of its former opponent, whilst a small cutting claw regenerates in place of the latter. When the same loss has befallen a lobster this reversal in the type of claws, as we have observed, will not occur, a crushing claw arising directly by regeneration, the cutting claw remaining as it was. As the type of a given body-side is thus not changed in the claw, we are able to decide in triplicities of a lobster's claw, if one of the components belongs to the other body-side by its type. Fortunately, this sort of monstrosity is not rarely found in lobsters and related species, so that comparisons can be made between supernumeraries on the crushing and cutting claws. On the latter they are always cutters, on the former typical crushers or transitional forms. These latter are easily explained as an earlier stage in the development of every crushing claw. So we can conclude that not only the components with the asymmetry proper to the body-side on which the triplication has appeared, but also the one between these, notwithstanding its mirror-image orientation, is not to be regarded as a limb belonging to the other side, but simply as a proximal outgrowth from a wound of the claw on the same side. The mirroring is accounted for by the anterior margin of the original claw always giving rise to an anterior margin again, the posterior to a posterior one, the dorsal to a dorsal, the ventral to a ventral. Although this example and most regenerations after amputation of parts or whole members by transverse cuts seem to indicate that not only will every tissue produce its own kind, but also the special differentiation it has undergone itself, such a sweeping statement would not be in accord with other facts.

Dual Faculty.—We have already treated of cases in which a dual faculty is revealed by heteromorphic regeneration. Another classical object is the lens of the newt's eye, which during embryological development is formed by the infolding of external skin, but if extracted later is replaced by regeneration from the iris. When bones are totally removed from limbs of newts or salamanders, leaving all the other parts in place, no regeneration of the excised bone is observed. But if now the limb is severed, the plane of amputation passing where the distal end of the removed bone should have been a blastema of regenerating cells will make its appearance. Although no bone is present at its base, this blastema will not only regenerate the general form of the limb, but also all the bones which normally lie distal to the plane of amputation. It is then clear that we have long been cheated by the coincidence of all tissues being present at a cut surface and the orientation of the margins remaining constant to believe in a necessity of the presence of tissues for regeneration which in reality may arise anew in the undifferentiated cells of the regeneration-bud. Remembering the use lower animals make of interstitial cells for restoring their form, we are again led to the conclusion that indifferent material is moulded by a formative agency. It is at present not possible to decide what category of force may be involved. Therefore, in order not to bias further investigation, the term field of force, as used by physicists and chemists, has been applied to regions where formative influences are at play in the organism. Many views have been taken as to the nature of these influences, starting from a crude predetermina-

REGENERATION IN THE LOBSTER (*HOMARUS VULGARIS*)

1, 2 and 3. Three stages of regeneration in the big or crushing claw

4, 5 and 6. Three stages of regeneration of both claws

7. Regeneration stage of the small or nipping claw

8. Triplicity of the penultimate segment or propodite from a lobster's claw found in nature, probably due to regeneration

9. Lobster lying on its back, showing triplicity of the last segment, or dactylopodite in the right crushing claw

In figs. 1–7, the lobsters are represented lying on their backs: The crusher is on the right body-side, the abdomen is not shown. In figs. 8 and 9 note the conformation of three components in the triplicate structure to Bateson's rules; the middle structure being the mirror-image to the others, all three belonging to one plane

tism and merging into conceptions of processes not acting point by point, but more after the manner of electric or magnetic induction, every point of the system being connected with the other by quantitative relations not altered when the size is changed. It has been pointed out how this view harmonizes with the regeneration from a cut surface after extraction of the bone or when a complete structure appears at the end of both parts of a split wound.

Defective Regeneration.—Other facts apparently supporting this conclusion have been found in defective or incomplete regeneration. We have till now only been describing new formations in which either the loss has been totally repaired or another structure taken its place or, lastly, supernumerary parts have arisen. Yet there are typical regenerative phenomena in which none of these possibilities are realized, the restorative process stopping before completion. The earthworm, when its head-region is amputated, does not regenerate as many segments as have been cut off. Stick-insects and other orthoptera with five-jointed tarsi in their limbs replace as a rule only four joints after autotomy. In water-fleas (*Daphnia*), joints in the second antenna are omitted during regeneration. Now in all these instances the terminal endings are always present, the defect resulting from the omission of basal segments. This also occurs in the newt's leg when insufficient material is available for regeneration. This has been especially observed when small regeneration buds are transplanted to another field of regeneration. If the regenerate were growing step by step we would rather expect the basal structures to be present, the distal to be inhibited, when there is a shortage of material. A field of force, on the contrary, could be imagined first laying out the margins and filling up the gaps as best possible afterwards. Captivating as this appears, yet there are other modes of explanation. If we take the direction of growth into account, we find that in the cases cited normal growth does not proceed all the time from the base towards the apex but reverses its direction after the most basal segments have been formed, so that the apex has grown before the segments just in front of it have developed. Therefore the segments omitted in regeneration are those which ought to be last constricted off and would be stopped first in case of deficiency. It is then not necessary to invoke a special action of the field as a whole.

Physiological Gradients.—Regions of active growth may be recognized by high rates of metabolism and physiological gradients made apparent by placing organisms into solutions which change colour on being acted on by the products of metabolic processes. (*See* AXIAL GRADIENT.) In the lower animals, with high regenerative capacities, these gradients are seen to be directed from the head backwards, so that some authors have ventured to attribute the reversion of polarity in cases of heteromorphosis to a high gradient arising through isolation of the head-piece at its new free surface in connection with the higher metabolic rate induced by the external stimuli. But it has not been possible to identify the head-formation with a special magnitude of metabolism, and as a second gradient is normally present passing from the tip of the tail forward it does not seem as if the special forms of head or tail could be explained by one sort of gradient.

Intimate Structure.—It seems necessary to postulate differences of a qualitative sort in the intimate structure of the body-regions to explain the different result, when an anterior or when a posterior piece has been isolated and has in the first case produced a reversed head, in the second a reversed tail, although in both cases the exposure to external stimuli was the same. It may well be that the physiological gradients are set up by differences in this intimate structure. It is also clear that fields of force must arise from a heterogenous source if they are to be able to produce such complicated forms as we see developing in the long axis and in the members of organisms. What remains to be discovered is how such an intimate structure is able to evolve from protoplasmatic cells which must at the beginning (for instance in the egg) contain all potentialities, as experiments with division of eggs producing several whole embryos show. (*See* EXPERIMENTAL EMBRYOLOGY.) Thus there is a gradual decrease in regenerative potencies with increasing development, whether this be taken as the succession of different stages during the ontogeny of an animal or as the differentiation of regions from the centre of the body towards its periphery or even the attainment of a higher level during evolution of the species. The underlying principle may then be stated as a differentiation of special potencies from an originally unspecialized mass. If we consider different formative processes going on at the same time with different velocities in the developing organism, we have still to account for the orientation the structures show towards each other, when they arise by the various morphogenetic phenomena proceeding with unequal velocity in different directions of the body. This problem, however, does not need a special solution in the realm of regeneration, as here we are always dealing with masses showing in part the definite orientation of the axes in the animal. There can be no doubt that these already definitely oriented systems induce the blastemas of regeneration to conform to their scheme. (*See* also HETEROMORPHOSIS; GRAFTING IN ANIMALS; GROWTH.)

REGENERATIVE FURNACE: *see* FURNACES, METALLURGICAL.

REGENSBURG (RATISBON), a city and episcopal see of Germany, in the republic of Bavaria, and the capital of the Government district of the Upper Palatinate. Pop. (1925) 76,948. It is situated on the right bank of the Danube, opposite the influx of the Regen, 86 m. by rail N.E. from Munich, and 60 m. S.E. of Nürnberg. The pre-Roman settlement of *Radespona* was chosen by the Romans, who named it *Castra Regina*, as the centre of their power on the upper Danube. It afterwards became the seat of the dukes of Bavaria, and was the focus from which Christianity spread over southern Germany. St. Emmeran founded an abbey here in the middle of the 7th century, and St. Boniface established the bishopric about 100 years later. Regensburg acquired the freedom of the empire in the 13th century, and was for a time the most flourishing city in southern Germany. It became the chief seat of the trade with India and the Levant, and the boatmen of Regensburg are frequently heard of as expediting the journeys of the crusaders. Numerous imperial diets were held here in the middle ages, and, after 1663, it became the regular place of meeting of that body. The Reformation found only temporary acceptance at Regensburg, and was met by a counter-reformation inspired by the Jesuits. Before this period the city had almost wholly lost its commercial importance owing to the changes in the great highways of trade. Regensburg is said to have suffered in all no fewer than 17 sieges. In 1810 the town and bishopric were ceded to Bavaria. In 1809 the French reduced a great part of the city to ashes.

Across the river is Stadt-am-Hof, connected with Regensburg by a stone bridge of the 12th century. One of the most characteristic features in its architecture is the number of strong loop-holed towers attached to the more ancient dwellings.

The cathedral, though small, is a very interesting example of pure German Gothic. It was founded in 1275, and completed in 1634, with the exception of the towers, which were finished in 1869. Adjoining the cloisters are two chapels of earlier date than the cathedral itself, one of which, known as the "old cathedral," goes back perhaps to the 8th century. The church of St. James—also called Schottenkirche—a plain Romanesque basilica of the 12th century, derives its name from the monastery of Irish Benedictines ("Scoti") to which it was attached. The old parish church of St. Ulrich is a good example of the Transition style of the 13th century. Examples of the Romanesque basilica style are the church of Obermünster, dating from 1010, and the abbey church of St. Emmeran, built in the 13th century, and remarkable as one of the few German churches with a detached belfry. The cloisters of the ancient abbey, one of the oldest in Germany, are still in fair preservation. In 1809 the conventual buildings were converted into a palace for the prince of Thurn and Taxis. The town hall, dating in part from the 14th century, contains the rooms occupied by the imperial diet from 1663 to 1806. Among the chief manufactures are pottery, parquet flooring,

musical instruments, furniture, sugar, chemicals, tobacco and lead pencils.

REGENT, one who rules or governs, especially one who acts temporarily as an administrator of the realm during the minority or incapacity of the king. This latter function, however, is one unknown to the English common law. "In judgment of law the king, as king, cannot be said to be a minor, for when the royal body politic of the king doth meet with the natural capacity in one person the whole body shall have the quality of the royal politic, which is the greater and more worthy and wherein is no minority." But for reasons of necessity a regency, however anomalous it may be in strict law, has frequently been constituted both in England and Scotland. The earliest instance in English history is the appointment of the earl of Pembroke with the assent of the loyal barons on the accession of Henry III.

Lord Coke recommends that the office should depend on the will of parliament (*Inst.*, vol. iv. p. 58), and in modern times provision for a regency has always been made by Act of parliament. As late as 1704 provision was made for a regency after the death of Anne. The earliest regency in England resting upon an express statute was that created by 28 Hen. VIII. c. 7, under which the king appointed his executors to exercise the authority of the crown till the successor to the crown should attain the age of 18 if a male or 16 if a female.

The Act of 5 Geo. III. c. 27 vested in the king power to appoint a regent under the sign manual, such regent to be one of certain named members of the royal family. Owing to the king's insanity in 1810 the Act of 51 Geo. III. c. 1 was passed, appointing the prince of Wales regent during the king's incapacity. The royal assent was given by commission authorized by both Houses of Parliament. By this Act no council of regency was appointed. There was no restriction on the regent's authority over treaties, peace and war, or over giving assent to bills varying the Act of Settlement or the Act of Uniformity, as in the previous Regency Acts, but his power of granting peerages, offices and pensions was limited. At the accession of William IV. the duchess of Kent was, by 1 Will. IV. c. 2, appointed regent, if necessary, until the Princess Victoria should attain the age of 18. By 10 Geo. IV. c. 7 the office of regent of the United Kingdom cannot be held by a Roman Catholic. A similar disability is imposed in most, if not all, Regency Acts.

REGER, MAX (1873–1916), German composer, was born at Brand, Bavaria, on March 19, 1873. He studied at Weiden, Sondershausen and Wiesbaden, and taught at the Royal academy, Munich, from 1905–07, when he became a teacher at the Leipzig conservatorium, a post which he retained until his death, on May 11, 1916. His early piano works, Variations on a Theme from Bach, Variations on a Theme from Beethoven, the Passacaglia and Fugue, and later the violin sonata in F sharp minor, which show already his individuality and remarkable technical powers, were followed by his first orchestral work, *Sinfonietta* (1906). After moving to Leipzig he wrote the violin concerto and piano concerto, with the powerful Symphonie Prologue to a Tragedy and the Comedy Overture, a number of choral pieces including *Die Nonnen, Der römische Triumphgesang* and *Die Weihe der Nacht,* the fine motets written for the Thomaner-Chor and the *Schlichte Weisen* sonatinas. From the period 1911–13, when he was also director of the court orchestra at Meiningen, there dates the Romantische Suite, Böcklin Suite, Ballet Suite, and later, Variations on a Theme from Mozart. From 1914 onwards his numerous compositions include many chamber works, pieces for choir and orchestra, for the piano and for the organ, and songs.

Reger was one of the most prolific and, in some respects, remarkably gifted composers of his day. His fertility was extraordinary, and he turned out work after work, often on the largest scale and in the most complex forms, with astonishing ease. His powers as a contrapuntist were especially noteworthy, and the fugue was one of his favourite forms. But as to the value of his immense output critical opinion is sharply divided.

A list of Reger's works is given in Grove's *Dict. of Music* (3rd ed., 1928). *See* also K. Hasse, *Max Reger* (Leipzig, 1921); E. Segnitz, *Max Reger* (Leipzig, 1922); and R. Würz, *Max Reger* (Munich, 1920).

REGGIO CALABRIA (anc. *Regium, q.v.*), a town and archiepiscopal see of Calabria, Italy, capital of the province of Reggio, on the Strait of Messina, 248 m. S.S.E. from Naples by rail. Pop. (1921) 53,959 (town); 59,430 (commune). It is the terminus of the railways from Naples along the west coast, and from Metaponto along the east coast of Calabria. The straits are here about 7 m. wide, and the distance to Messina nearly 10 m. The ferryboats to Messina therefore cross by preference from Villa S. Giovanni, 8 m. N. of Reggio, now included within its communal boundary, whence the distance is only 5 m. In 1894 the town suffered from an earthquake, though less severely than in 1783. It was totally destroyed, however, by the great earthquake of December 1908; in the centre of the town about 35,000 out of 40,000 persons perished. The cathedral, which dated from the 17th century, and the ancient castle which rose above it, were wrecked. Great damage was done by a seismic wave following the shock. (*See* MESSINA.)

REGGIO EMILIA, a city and episcopal see of Emilia, Italy, the capital of the province of Reggio Emilia (till 1859 part of the duchy of Modena), 38 m. by rail N.W. of Bologna. Pop. (1906) 19,681 (town) 64,548 (commune); (1921) 49,524 (town) 82,915 (commune). The town is in the shape of a diamond. The cathedral, originally erected in the 12th century, was reconstructed in the 15th and 16th; the façade shows traces of both periods, the Renaissance work by Prospero Spani (1516–1584) being complete only in the lower portion. The Madonna della Ghiara, built in 1597–1619 in the form of a Greek cross, is beautifully proportioned and finely decorated in stucco and with frescoes of the Bolognese school of the early 17th century. S. Prospero has a good façade of 1753. There are several good palaces of the early Renaissance, a fine theatre (1857) and a museum containing important palaeo-ethnological collections, ancient and mediaeval sculptures, and the natural history collection of Lazzaro Spallanzani. Lodovico Ariosto, the poet (1474–1533), was born in Reggio, and his father's house is still preserved. The industries embrace the making of railway locomotives and carriages and tramcars, and of cheese.

Regium Lepidi was probably founded by M. Aemilius Lepidus during the construction of the Via Aemilia (187 B.C.), on which it lay half-way between Mutina and Parma. It was during the Roman period a flourishing town. The bishopric dates perhaps from the 4th century A.D. Under the Lombards the town was the seat of dukes and counts; in the 12th and 13th centuries it formed a flourishing republic, busied in surrounding itself with walls (1229), controlling the Crostolo and constructing navigable canals to the Po. About 1290 it first passed into the hands of Obizzo d'Este, and the authority of the Este family was finally recognized in 1409.

REGICIDE, the name given to anyone who kills a sovereign (Lat. *rex*, a king, and *caedere*, to kill). Regicides is the name given in English history at the Restoration of 1660 to those persons who were responsible for the execution of Charles I. The number of regicides was estimated at 84, this number being composed of the 67 present at the last sitting of the court of justice, 11 others who had attended earlier sittings, four officers of the court and the two executioners.

The trial of the regicides before a court of 34 commissioners took place in Oct. 1660. Twenty-nine were condemned to death, but only ten were actually executed, the remaining 19 with six others being imprisoned for life. The ten who were executed at Charing Cross or Tyburn, London, in Oct. 1660, were Thomas Harrison, John Jones, Adrian Scrope, John Carew, Thomas Scot and Gregory Clement, who had signed the death-warrant; the preacher Hugh Peters; Francis Hacker and Daniel Axtel, who commanded the soldiers at the trial and the execution of the king; and John Cook the solicitor who directed the prosecution.

In Jan. 1661 the bodies of Cromwell, Ireton, and Bradshaw were exhumed and hanged at Tyburn, but Pride's does not appear to have been treated in this way. Of the nineteen or twenty regicides who had escaped and were living abroad, three, Sir John Barkstead, John Okey and Miles Corbet, were arrested in Holland and executed in London in April 1662; and one, John Lisle, was

murdered at Lausanne. The last survivor of the regicides was probably Edmund Ludlow, who died at Vevey in 1692.

BIBLIOGRAPHY.—Ludlow's *Memoirs*, edited by C. H. Firth (Oxford, 1894), give interesting details about the regicides in exile. *See* also D. Masson, *Life of Milton*, vol. vi. (1880), and M. Noble, *Lives of the English Regicides* (1798); L. E. Welles, *History of the Regicides* (1927).

REGILLUS, an ancient lake of Latium, Italy, famous in the legendary history of Rome as the lake in the neighbourhood of which occurred (496 B.C.) the battle which finally decided the hegemony of Rome in Latium. Of the various sites proposed, the best is Pantano Secco, some 2 m. N. of Frascati.

REGINA, the capital city of the province of Saskatchewan, Canada, situated at 104° 36′ W. and 50° 27′ N., and 357 m. W. of Winnipeg. Pop. (1926), 37,329. After the Canadian Pacific railway was completed in 1885, the necessity for a place of government on the railway line pressed itself upon the Dominion government. The North-West Territories were but little settled then, but a central position on the prairies was necessary, where the mounted police might be stationed and where the numerous Indian bands might be easily reached. The minister of the interior at Ottawa, afterwards Governor Dewdney, chose this spot, and for a number of years Regina was the seat of the Territorial government. The governor took up his abode on the adjoining plain, and the North-West Council met each year, with a show of constitutional government about it. On the formation of the province of Saskatchewan in 1905 the choice of capital was left to the first legislature of the province. Prince Albert, Moose Jaw and Saskatoon all advanced claims, but Regina was decided on as the capital.

The city has a large distributing trade and is the central market for an agricultural region. It is on the Canadian Pacific and Canadian National railways, and has 12 radiating lines. There are many mills, banks, wholesale houses and factories, including a large oil refinery. Regina is the western headquarters of the Royal Canadian Mounted Police.

REGINON, or **REGINO OF PRÜM,** mediaeval chronicler, was born at Altripp near Spires, and was educated in the monastery of Prüm. Here he became a monk, and in 892, just after the monastery had been sacked by the Danes, he was chosen abbot. In 899, however, he was deprived of this position and he went to Trier, where he was appointed abbot of St. Martin's. He died in 915, and was buried in the abbey of St. Maximin at Trier, his tomb being discovered there in 1581.

Reginon wrote a *Chronicon*, dedicated to Adalberon, bishop of Augsburg (d. 909), which deals with the history of the world from the commencement of the Christian era to 906, especially with the affairs in Lorraine. The chronicle was first published at Mainz in 1521; another edition is in Band I. of the *Monumenta Germaniae historica. Scriptores* (1826); the best is the one edited by F. Kurze (Hanover, 1890); German trans. by W. Wattenbach (Leipzig, 1890). Reginon also drew up at the request of his patron, Radbod, archbishop of Trier (d. 915), a collection of canons, *Libri duo de synodalibus causis et disciplinis ecclesiasticis;* this is published in Migne's *Patrol. Lat.* t. 132.

See H. Ermisch, *Die Chronik des Regino bis 813* (Göttingen, 1872); P. Schulz, *Die Glaubwürdigkeit des Abtes Regino von Prüm* (Hamburg, 1894); C. Wawra, *De Reginone Prumensis* (Breslau, 1901).

REGIOMONTANUS (1436–1476), German astronomer, was born at Königsberg in Franconia on June 6, 1436. His name originally was Johann Müller, but he called himself, from his birthplace, Joh. de Monteregio, an appellation which became modified into Regiomontanus. At Vienna, from 1452, he was the pupil and associate of George Purbach (1423–1461), and they jointly undertook a reform of astronomy rendered necessary by the errors they detected in the Alphonsine Tables. In this they were much hindered by the lack of correct translations of Ptolemy's works; and in 1462 Regiomontanus accompanied Cardinal Bessarion to Italy to study a copy of the *Almagest*. He rapidly mastered Greek at Rome and Ferrara, lectured on Alfraganus at Padua, and completed at Venice in 1463 Purbach's *Epitome in Cl. Ptolemaei magnam compositionem* (printed at Venice in 1496), and his own *De Triangulis* (Nuremberg, 1533), a treatise on trigonometry. In 1468 he returned to Vienna, and was thence summoned to Buda by Matthias Corvinus, king of Hungary, for the purpose of collating Greek manuscripts. He also finished his *Tabulae Directionum* (Nuremberg, 1475), essentially an astrological work, but containing a valuable table of tangents.

In 1471 Regiomontanus settled at Nuremberg. Bernhard Walther, a rich patrician, became his pupil and patron; and they together equipped the first European observatory, for which Regiomontanus himself constructed instruments of an improved type (described in his posthumous *Scripta*, Nuremberg, 1544). His observations of the great (Halley's) comet of 1472 supplied the basis of modern cometary astronomy. At a printing-press established in Walther's house by Regiomontanus, Purbach's *Theoricae planetarum novae* was published in 1472 or 1473; a series of popular calendars issued from it, and in 1474 a volume of *Ephemerides* calculated by Regiomontanus for thirty-two years (1474–1506), in which the method of "lunar distances," for determining the longitude at sea, was recommended and explained. In 1472 Regiomontanus was summoned to Rome by Pope Sixtus IV., to aid in the reform of the calendar; and there he died on July 6, 1476.

See P. Gassendi, *Vita Jo. Regiomontani* (Parisiis, 1654); and the general histories of astronomy.

REGIONAL PLANNING, a term used by community planners, engineers and geographers to describe a comprehensive ordering of the natural resources of a community, its material equipment and its population for the purpose of laying a sound physical basis for the "good life." In America the term has also been used to describe plans for city extension over wide metropolitan areas; this type of planning should properly be called metropolitan planning. Regional planning involves the development of cities and countrysides, of industries and natural resources, as part of a regional whole.

The programme of regional planning has grown out of a multitude of fresh initiatives; the activities of foresters and conservationists with forest working plans, of engineers with water power plans, of municipal engineers with plans for city extensions and parkways, and finally, of a great school of regional geographers, who, under Vidal de la Blache in France, Herbertson in England, Fenneman, Smith and others in the United States, have established the region as a definite unit, with its special individuality of geologic formation, climate, vegetation, landscape and human culture. The method of the regional plan can perhaps best be grasped by considering its simpler prototype, that which covers but a single aspect of regional life. Take an actual forest working plan for an area in the State of Washington, between the Cascade range and Puget sound: it is about the size of Rhode Island. Except for the mountain barrens and narrow strips of agricultural land along the rivers, the whole region is under forest. The plan divides this area into six "cutting-blocks," each block to be cut within a ten year period and the logs hauled to a central saw mill. When the last block has been cut over the first is ready to be cut again. The central mill and the houses provided for its working force are permanent fixtures.

This plan brings out the essential characteristics of every regional plan, whether specialized or comprehensive. (1) It deals with a geographic area; (2) it surveys that area and discovers its natural characteristics and resources; (3) it suggests a method of conserving its resources and developing its economic life; (4) it erects relatively permanent seats of human habitation, with all the social facilities that derive from such stability. Lacking such a plan and such a public policy, current commercial methods of exploitation would cut over the entire area in one operation, would provide only temporary employment and temporary habitations, would make no provision for natural reforestation, and would, as a result, permit the soil of the timber-mined area to be washed away, degrading the whole region and making further human activity difficult, if not impossible in it.

The Means to an End.—A regional plan, if it is really a plan and not a description, deals not only with a geographic area but with a force or "flow" or group of activities taking place within it. This flow may consist of water or electricity or commodities like lumber, wheat, dairy produce, manufactured articles—some product required for human sustenance. The flow may also be that of population; this includes industrial plant and social institutions—schools, libraries, churches, colleges, museums, hospitals

—in short, a flow of civilization. We usually regard these things as static; actually, they are always in motion, improving, deteriorating, changing their position, if not from year to year, then from decade to decade. Regional planning would direct and modify these changes to the advantage of the whole community, instead of simply letting them "happen." A comprehensive regional plan involves not merely the forces of man's industrial life but his cultural activities as well; for plans that concern themselves solely with the means of life are in danger of defeating man's cultural activities, which express his aims or objectives. In contrast to the view of industrial production almost universally accepted during the 19th century, regional planning recognizes that the means must be subordinate to the ends. Thus, in utilizing sites along a river, the regional planner may reserve for recreation a spot that would ordinarily be dedicated to heavy manufacturing; or between two possible types of industry, he may select that which has a higher civilization-value. Regional planning, following Ruskin, recognizes as the ultimate product of industry not money or commodities but human life. Briefly, regional planning deals with the ecology of the human community. Just as plant ecology treats of the climate, soil, the plant and insect partnerships necessary to the existence of a species of plants, so regional planning deals with the climate, vegetation, minerals, power resources, landscape, economic and social institutions necessary to a flourishing human community. It is not an effort to make a region self-subsistent; it *is* an attempt to bring it into the highest state of economic and human cultivation. No region is a self-contained unit. Except for islands and isolated mountain areas, there are no self-contained units even in the narrow geographic sense, whilst economically and culturally no region has existed without contact with other regions. Inter-regional relationships are just as important as internal ones, and of as much concern to the regional planner. Thus it has been pointed out that the only fundamental solution of New York's congestion of population and traffic involves a redistribution of the flow of commodities through the Atlantic ports, decreasing the share that now falls to New York, and redistributing part of New York's growing population in regional cities outside the immediate metropolitan area. Such a programme was partly sketched out in the final report of the New York State Housing and Regional Planning commission (1926).

Aspects.—In the countries where there is regional planning one aspect or another has usually been dominant, although regional planning involves every aspect of a region's life. In France, for example, the necessity for political administrative units that bear some relation to economics, history and geography has made the political side dominant; similar considerations have governed the drawing up of new governmental units in Siberia. Regional survey brings out the arbitrary nature of a great many political boundaries, and suggests the possibility of re-drawing them, or of co-operatively ignoring them, as in the constitution of the New York-New Jersey port authority. Economically, regional planning seeks the fullest development of local resources and skills, without the extravagant waste and degradation that accompanied this process in the past; in America this aspect of regional planning has been uppermost in the work of foresters and conservationists like Gifford Pinchot and Liberty Hyde Bailey. Socially, regional planning attempts to curb the growth of metropolitan slums and to create independent cities in more effective relationship with nature and industry and to take care of further increments of population: in England, the garden city movement, which has built Letchworth and Welwyn, has emphasized this side of regional planning. In reports on the Deeside and the Doncaster districts in England, and the newly found coal-areas in Kent, as well as in the final report of the New York State Housing and Regional Planning commission, these various aims have been co-ordinated and focussed. Regional rather than metropolitan development has been aided by motor transport and the aeroplane, by the radio, telephone, and giant power; and regional planning tends to make the fullest use of these. Similar reports and surveys have been made for the Ruhr district in Germany, for the French Alps, and, on a smaller scale, for agricultural communities in the Caucasus.

Among the precursors and intellectual preceptors of the modern regional planning movement, one must note Auguste Comte and Frédéric Le Play in political decentralization, Henry Thoreau in philosophy, George Perkins Marsh, author of *The Earth as Modified by Human Action*, Reclus, Ratzel and Shaler in geography, Kropotkin in economics, and Patrick Geddes, whose social studies and technical initiatives as city planner have touched every part of it. The first conception of dealing with the administration of modern utilities like electricity on a regional, rather than a national or local scale, was embodied in a Fabian pamphlet in the "New Heptarchy Series" on *Municipalization by Provinces;* the first definitive project for a regional city was that issued by Sir Ebenezer Howard in *Tomorrow* (*see* GARDEN CITIES) while numerous books and reports have appeared during the last twenty years.

REGIUM, a city of the territory of the Bruttii in South Italy, on the east side of the strait between Italy and Sicily (*see* REGGIO). A colony, mainly of Chalcidians, partly of Messenians from the Peloponnesus, settled at Regium in the 8th century B.C. About 494 B.C. Anaxilas, a member of the Messenian party, made himself master of Regium (apparently with the help of the Samians: *see* MESSINA) and about 488 joined with them in occupying Zancle (Messina). In 433 Regium made a treaty with Athens, and in 427 joined the Athenians against Syracuse, but in 415 it remained neutral. An attack which it made on Dionysius I. of Syracuse in 399 was the beginning of a great struggle which in 387 resulted in its complete destruction and the dispersion of its inhabitants as slaves: but it soon recovered its prosperity. In 280, Pyrrhus invaded Italy, the Regines admitted within their walls a Roman garrison of Campanian troops; these mercenaries revolted, massacred the male citizens, and held the city till in 270 they were besieged and put to death by the Roman consul Genucius. The city remained faithful to Rome throughout the Punic wars, and Hannibal never succeeded in taking it. It took the name Regium Iulium under Octavius (Augustus); and the pedestal of a statue erected in his honour (as Augustus) has recently been found there. It continued to be a Greek city even under the Empire. Towards the end of the Empire it was made the chief city of the Bruttii.

See P. Larizza, *Rhegium Chalcidense* (Rome, 1905); Orsi in *Notizie degli scavi,* 1922, 151 *sqq.*

REGIUM DONUM or ROYAL GIFT, an annual grant formerly made from the public funds to Presbyterian and other Nonconformist ministers in Great Britain and Ireland. In 1690 William III. made a grant of £1,200 a year to the Presbyterian ministers in Ireland as a reward for their services during his struggle with James II. Owing to the opposition of the Irish House of Lords the money was not paid in 1711 and some subsequent years, but it was revived in 1715 by George I., who increased the amount to £2,000 a year. Further additions were made in 1784 and in 1792, and in 1868 the sum granted to the Irish Presbyterian ministers was £45,000. The Regium Donum was withdrawn by the act of 1869 which disestablished the Irish church. Provision was made, however, for existing interests therein, and many Presbyterian ministers commuted these on the same terms as the clergy of the church of Ireland.

In England the Regium Donum proper dates from 1721, when Dr. Edmund Calamy (1671–1732) received £500 from the royal bounty "for the use and behalf of the poor widows of dissenting ministers." Afterwards this sum was increased to £1,000 and was made an annual payment "for assisting either ministers or their widows," and later it amounted to £1,695 per annum. It was given to distributors who represented the three denomina-

tions, Presbyterians, Baptists and Independents, enjoying the grant. Among the Nonconformists themselves, however, or at least among the Baptists and the Independents, there was some objection to this form of state aid, and it was withdrawn in 1857.

See J. Stoughton, *History of Religion in England* (1901); J. S. Reid, *History of the Presbyterian Church in Ireland* (Belfast, 1867); and E. Calamy, *Historical Account of my own Life*, edited by J. T. Rutt (1829–30).

REGLA, formerly an important suburb of Havana, Cuba, opposite that city, on the bay; now a part of Havana. Pop. (1926) about 30,000. It was formerly the scene of the Havana bull-fights. The church is one of the best in Cuba; the building dates substantially from 1805, but the church settlement goes back to a hermitage established in 1690. Regla is the shipping-point of the Havana sugar trade. It has enormous sugar and tobacco warehouses, fine wharves, a dry-dock, foundries and an electric railway plant. It is the western terminus of the eastern line of the United Railways of Havana, and is connected with the main city of Havana by ferry. A fishing village was established here about 1733. At the end of the 18th century Regla was a principal centre of the smuggling trade, and about 1820 was notorious as a resort of pirates. It first secured an *ayuntamiento* (city council) in 1872, and after 1899 was annexed to Havana.

REGNARD, JEAN FRANÇOIS (1655–1709), French comic dramatist, was born in Paris on Feb. 7, 1655. His masterpieces are *Le Joueur* (Théâtre Français, Dec. 19, 1696), and *Le Légataire universel* (1708). Regnard died on Sept. 4, 1709.

Besides many plays Regnard wrote miscellaneous poems, the autobiographical romance of *La Provençale*, and several short accounts in prose of his travels, published posthumously under the title of *Voyages*.

The first edition of Regnard's works was published in 1731 (5 vols., Rouen and Paris). There is a good selection of almost everything important in the Collection Didot (4 vols., 1819). A selection by L. Moland appeared in 1893. *See* also a *Bibliographie et iconographie des oeuvres de J. F. Regnard* (Paris, Rouquette, 1878); *Le Poète J. F. Regnard en son chasteau de Grillon*, by J. Guyot (Paris, 1907).

REGNAULT, HENRI (1843–1871), French painter, born at Paris on Oct. 31, 1843, was the son of Henri Victor Regnault (*q.v.*). He studied successively under Montfort, Lamothe and Cabanel, and in 1864 exhibited two portraits at the Salon. In 1866, he gained the *Grand Prix* with "Thetis bringing the Arms forged by Vulcan to Achilles" (Beaux-Arts). In Rome Regnault came under the influence of the modern materialistic Hispano-Italian school. His paintings include an imaginative picture of Marshal Prim at the head of his troops, inspired by a glimpse of his subject, received when travelling in Spain; "Judith" (1870), "Salome" and the realistic "Execution without Hearing under the Moorish Kings," painted at Tangiers. Regnault was killed in the Franco-German War on Jan. 19, 1871, while serving under Buzenval.

See *Correspondance de H. Regnault;* Duparc, *H. Regnault, sa vie et son œuvre;* Cazalis, *H. Regnault, 1843–1871;* C. Blanc, *H. Regnault.*

REGNAULT, HENRI VICTOR (1810–1878), French chemist and physicist, was born on July 21, 1810, at Aix-la-Chapelle. His early life was a struggle with poverty, he worked in a drapery establishment in Paris until 1829. Then he entered the École Polytechnique, and passed in 1832 to the École des Mines. A few years later, after studying under Liebig (*q.v.*), he was appointed to a professorship of chemistry at Lyons. His most important contribution to organic chemistry was a series of researches, begun in 1835, on the halogen and other derivatives of unsaturated hydrocarbons. He also studied the alkaloids and organic acids, introduced a classification of the metals and effected a comparison of the chemical composition of atmospheric air from all parts of the world. In 1840 he became professor of chemistry in the École Polytechnique, Paris; he was elected a member of the Academie des Sciences, and in 1841 he succeeded Dulong (*q.v.*), professor of physics in the Collège de France. In 1847 he published a four-volume treatise on *Chemistry* which has been translated into many languages. Regnault's work in physics was remarkably accurate and painstaking. He designed apparatus for a large number of measurements which is the standard apparatus of the present.

Regnault executed a careful redetermination of the specific heats of many solids, liquids and gases. (*See* CALORIMETRY.) He investigated the expansion of gases by heat, and showed that, contrary to previous opinion, no two gases had precisely the same coefficient of expansion. By delicate experiments he proved that Boyle's law is only approximately true for real gases. He studied the subject of thermometry (*q.v.*) critically; he introduced the use of an accurate air-thermometer, and compared its indications with those of a mercurial thermometer, determining the absolute expansion of mercury as a step in the process. He also paid attention to hygrometry and devised Regnault's hygrometer.

In 1854 he was appointed as director of the porcelain manufactory at Sèvres. He carried on his great research on the expansion of gases in the laboratory at Sèvres, but all the results of his latest work were destroyed during the Franco-German War, in which also his son Henri (noticed above) was killed. Regnault never recovered from the double blow, and, although he lived until Jan. 19, 1878, his scientific labours ended in 1872. Regnault's most important work is collected in vols. 21 and 26 of the *Mémoires de l'Académie des Sciences.*

RÉGNIER, HENRI FRANÇOIS JOSEPH DE (1864–), French poet and novelist, was born at Honfleur (Calvados) on Dec. 28, 1864, and was educated in Paris for the law. In 1885 he began to contribute to the Parisian reviews, and his verses found their way into most of the French and Belgian periodicals favourable to the symbolist writers. Having begun, however, to write under the leadership of the Parnassians, he retained the classical tradition, though he adopted some of the innovations of Moréas and Gustave Kahn. His gorgeous and vaguely suggestive style shows the influence of Stéphane Mallarmé. His first volume of poems, *Lendemains*, appeared in 1885, and among numerous later volumes are *Poèmes anciens et romanesques* (1890), *Les Jeux rustiques et divins* (1890), *Les Médailles d'argile* (1900), the most famous and the most read of his books of verse, and *La Cité des eaux* (1903). He is also the author of a series of realistic novels and tales, among which are *La Canne de jaspe* (2nd ed., 1897), *La Double Maîtresse* (5th ed., 1900), and *Les Amants singuliers* (1905).

His later works include: *L'Amphisbène* (1912); *La Pécheresse* (1920); *Vestigia Flammae* (7th ed., 1921); *Le Divertissement Provincial* (1925); *Proses datées* (1925); *L'Escapade* (1926).

See also E. Gosse, *French Profiles* (1905); van Bever and Leautaud, *Poètes d'aujourd'hui* (1900); H. Berton, *Henri de Régnier, le poète et le romancier* (1910); A. Lowell, *Six French Poets* (1915); and R. Honnert, *Henri de Régnier, son oeuvre* (1923).

RÉGNIER, MATHURIN (1573–1613), French satirist, was born at Chartres on Dec. 21, 1573, the son of Jacques Régnier, and Simone Desportes, sister of the poet. Little is known of his youth, except that he received the tonsure at eight years old, and it is chiefly conjecture which fixes the date of his visit to Italy in a humble position in the suite of the cardinal, François de Joyeuse, in 1587. Régnier found his duties irksome, and when, after many years of constant travel in the cardinal's service, he returned definitely to France about 1605, he took advantage of the hospitality of Desportes. In 1606 Desportes died and Régnier obtained a pension of 2,000 livres, chargeable upon one of Desportes' benefices. He was also made in 1609 canon of Chartres through his friendship with the lax bishop, Philippe Hurault, at whose abbey of Royaumont he spent much time in the later years of his dissipated life. The death of Henry IV. deprived him of his last hope of great preferments. He died at Rouen at his hotel, the Écu d'Orléans, on Oct. 22, 1613.

His undoubted work falls into three classes: regular satires in alexandrine couplets, serious poems in various metres, and satirical or jocular epigrams and light pieces, which often, if not always, exhibit considerable licence of language. The real greatness of Régnier consists in the vigour and polish of his satires, contrasted and heightened as that vigour is with the exquisite feeling and melancholy music of some of his minor poems. In these Régnier is a disciple of Ronsard (whom he defended brilliantly

against Malherbe), without the occasional pedantry, the affectation or the undue fluency of the Pléiade; but in the satires he seems to have had no master except the ancients, for some of them were written before the publication of the satires of Vauquelin de la Fresnaye, and the *Tragiques* of D'Aubigné did not appear until 1616. Régnier was an acute critic, and the famous passage (Satire ix., *À Monsieur Rapin*) in which he satirizes Malherbe contains the best denunciation of the merely "correct" theory of poetry that has ever been written. All his merits are displayed in the masterpiece entitled *Macette ou l'Hypocrisie déconcertée,* which does not suffer even on comparison with *Tartuffe;* but hardly any one of the sixteen satires which he has left falls below a very high standard.

Les Premières Oeuvres ou satyres de Régnier (1608) included the *Discours au roi* and ten satires. There was another in 1609, and others in 1612 and 1613. The author had also contributed to two collections—*Les Muses gaillardes* in 1609 and *Le Temple d'Apollon* in 1611. In 1616 appeared *Les Satyres et autres oeuvres folastres du sieur Régnier,* with many additions and some poems by other hands. Two famous editions by Elzevir (Leiden, 1642 and 1652) are highly prized. The chief editions of the 18th century are that of Claude Brossette (printed by Lyon & Woodman, London, 1729), which supplies the standard commentary on Régnier, and that of Lenglet Dufresnoy (printed by J. Tonson, London, 1733). The editions of Prosper Poitevin (Paris, 1860), of Ed. de Barthélemy (Paris, 1862), and of E. Courbet (Paris, 1875), may be specially mentioned. The last, printed after the originals in italic type, and well edited, is perhaps the best. *See* also Viancy's *Mathurin Régnier* (1896); M. H. Cherrier, *Bibliographie de Mathurin Régnier* (1884); Jean-Marc Bernard, *L'introducteur de la satire en France: Mathurin Régnier* (1913); Emile Roy, *Notes sur les deux poètes Jean et Mathurin Régnier* (1910).

REGNITZ, a river of Germany, 126 m. long, and a left-bank tributary of the Main. It rises in the Jurassic rocks of the Frankish Jura, but its course is along the Trias, through an undulating vine-clad country, past Fürth, Erlangen, Baiersdorf and Forchheim, from which point it is navigable, and joins the Main at Bischberg, below Bamberg. The Ludwigs canal connects it with the Main and the Danube. Its main tributaries are the Pegnitz, on which is Nurnberg, the Gründlach and the Wiesent (right) and the Zenn, the Aurach and the Aisch (left). (*See* MAIN and RHINE.)

REGRATING, in English criminal law, was the offence of buying and selling again in the same market, or within four miles thereof (O. Fr. *regrater,* to sell by retail). (*See* ENGROSSING.)

REGULA, the Latin word for a rule, hence particularly applied to the rules of a religious order. (*See* MONASTICISM.) In architecture the term is applied to a rule, a square and the short fillet or rectangular block, under the taenia (*q.v.*) on the architrave of the Doric entablature. (*See* ORDER.)

REGULAR (Lat. *regularis,* from *regula,* a rule, O.Fr. *reule*), orderly, following or arranged according to a rule, steady, uniform, formally correct. Until the sixteenth century the adjective was applied exclusively to the discipline and customs of religious orders bound by a rule, and to their members, who constituted the "regular" as opposed to the "secular" clergy. Thus, as a substantive, "regular" means a monk or friar; while there were bodies of canons regular and canons secular. In more recent military usage, the regular forces was the name for the standing army organised on a permanent system, as opposed to "irregulars," levies raised on a voluntary basis.

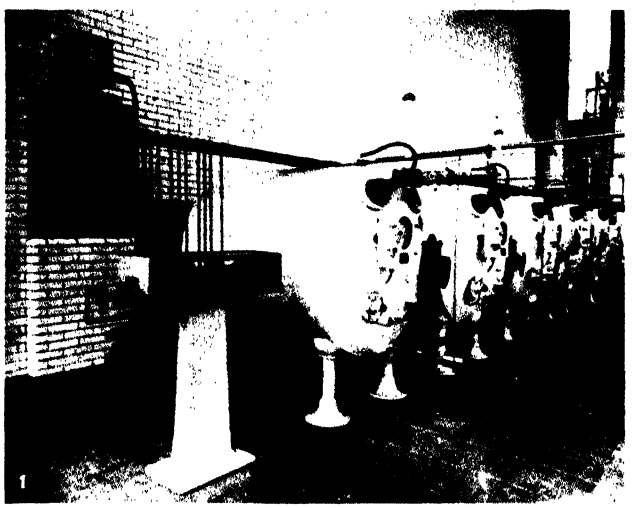
REGULATION, AUTOMATIC. Modern processing is required in the production of most of the articles of clothing, foodstuffs, and other items that are used in every day life. Processing requires proper conditions not only in workrooms but in the endless variety of boilers, ovens, furnaces, dryers, sterilizers and other types of apparatus. To insure the proper conditions the automatic regulation of *temperature, pressure, humidity, timing, liquid level, flow, specific gravity* of the substance being processed and *speed of moving parts* is of great importance. These eight conditions will be dealt with. *Voltage* (which must be regulated in many devices), *current density* (in electroplating, etc.) and other electrical conditions are discussed under INSTRUMENTS, ELECTRICAL, and ELECTRICITY. No discussion is here given of the regulators, controllers or governors incorporated in engines, turbines, generators and other such machines, since these devices as conceived, designed, built, sold, installed and maintained with the machines, belong to their machines and seldom can function on others.

Automatic regulation of the eight conditions listed above is, however, a science, and the proper application of standardized automatic regulators to improve products and effect economies is a prominent branch of engineering.

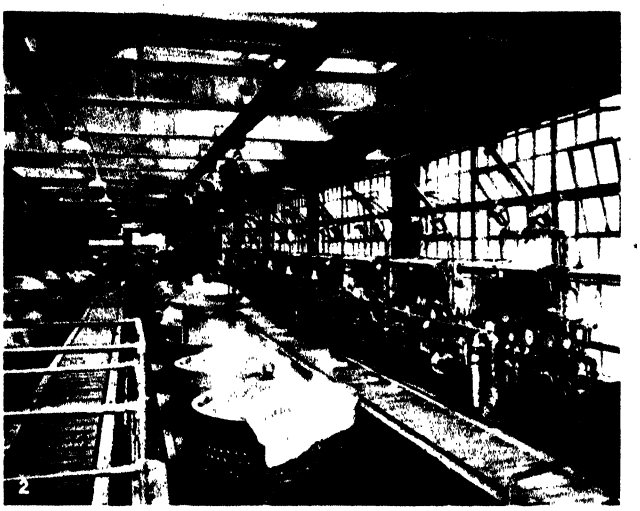
Development of Automatic Regulation.—For every industry it has been established that there is one best set of conditions for operation and manufacture. Before the World War, in searching for this "one best way," workers were frequently required to watch indicators and manipulate valves and levers constantly in order to maintain proper conditions, until a fairly suitable automatic device was purchased or painstakingly contrived. Today (1929) specialists may install the required automatic devices as soon as the particular requirements are known. One of the factors that have made this possible is the spread of knowledge of formerly secret processes. This has led to "professional divisions" within the larger engineering societies and to co-operative industrial "institutes" and research bureaux. Competition between industries has also led to the exchange of formulae and data on automatic processes. Instrument-makers have pursued an increasingly active policy of scientific research into processes, with two objectives: (1) the development and standardization of classes and types of automatic regulators, based on industrial requirements; (2) the improvement and standardization of processes through methods worked out by their research staffs.

All these tendencies point to the need of an agency for the systematic utilization of scientific achievements. A central "institute" under the auspices of instrument makers may ultimately be developed. The progress of the last decade will undoubtedly be eclipsed when manufactu: 's thus combine their research and present their united facilities to the instrument-using industries. For example, the standardization of bulbs, connections, protective sockets, thermocouples, charts, scales, ranges, etc., has been initiated in the United States, but as yet only on a small scale.

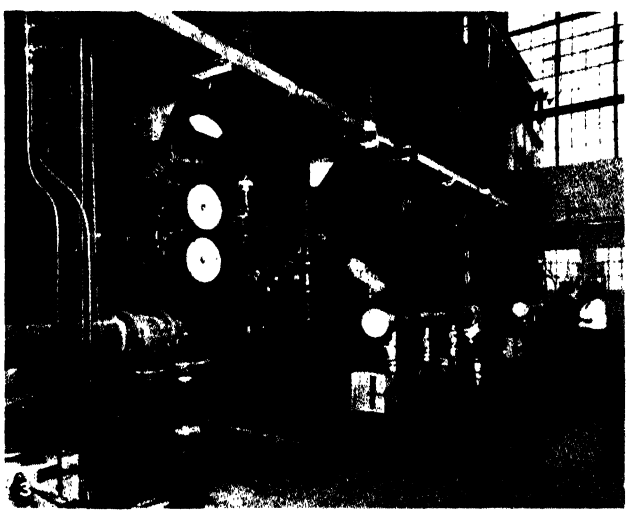
Types of Automatic Regulators.—All regulators require some form of power to operate a valve, damper, etc., in order to maintain the optimum condition.



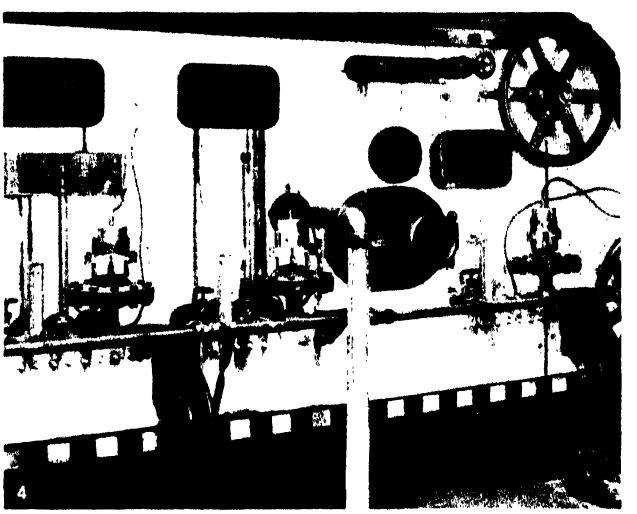
Self-operating regulators requiring no auxiliary power are directly installed (*i.e.*, on a steam line) and usually consist of a globe or balanced valve operated by a bellows; the expansion of the bellows being obtained in temperature regulators by the dilation or evaporation of a liquid in a sensitive bulb, and in pressure regulators by the pressure which is to be regulated. This group of devices includes thermostats and damper regulators.



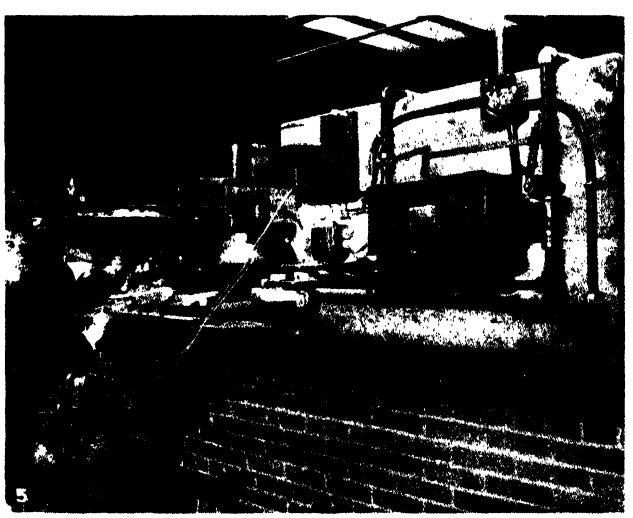
Air-operated regulators are the most wide-spread in industrial process service. They utilize the ample and flexible power of compressed air, controlling its flow to an operative mechanism which usually embodies an elastic diaphragm. Pilot valves add extreme sensitiveness to ample power, obviating the use of bellows—a small capsular or spiral spring or Bourdon tube being sufficient. (*See* Plate, figs. 6 and 7.)



Electrically operated regulators function on the relay principle and actuate standardized electrical mechanisms. Heavy work may be performed through their agency but their on-and-off action produces the frequently objectionable "saw-tooth" record. On a temperature application, for instance, the steam valve would "hunt" whereas air-operated regulators can provide exact throttling regulation. (*See* Plate, fig. 1.)



Steam-operated regulators utilize the power of the steam which they control. They embody the sensitive bulb, capillary tube and capsular spring. This latter operates a pilot valve so located that the pressure above a steam diaphragm may be varied with respect to the pressure below it. Pressure fluctuations of the steam supply cannot destroy accuracy, for the differential principle is used. Valves up to 4 in. are successfully operated by diaphragms up to 11 in. diameter. (*See* Plate, figs. 3 and 4.)



Temperature Systems. *Fixed Stem.*—It is sometimes possible to use the "solid expansion" principle, and the sensitive member then consists of a bimetallic stem (or of a carbon or quartz rod

BY COURTESY OF (1, 2, 4) THE C. J. TAGLIABUE MANUFACTURING COMPANY, (5) THE BROWN INSTRUMENT COMPANY, (3) THE REPUBLIC FLOW METERS COMPANY, (6, 7) THE FOXBORO COMPANY

INSTALLATIONS OF AUTOMATIC CONTROLLERS IN VARIOUS INDUSTRIES

1. Process controller in milk pasteurization. The automatic cycle controller, on the pedestal to left, regulates the filling of each of the separate pasteurization vats, to the right, with the proper quantity of milk; holds the fluid for the required length of time; maintains the proper heat at a uniform temperature, and empties the vats when the cycle has been completed. 2. Process controller in tyre manufacturing. Automatic combination controllers which maintain the correct cure temperature and the time in tyre vulcanization. 3. Regulating and indicating instruments in a modern boiler room, indicating and regulating the flow of steam, air, water and gas. 4. Steam-operated temperature controllers on a bottle washing machine. 5. Decorating lehr, or heated oven, in a glass plant. High grade perfumery bottles are pressed through the lehr for annealing and burning on the enamel decorations. An automatic control pyrometer governs the motor driven valve in the rectangular box to the right. 6. Interior of a temperature recorder-controller. Air-operated recorder showing helical tubes which actuate a flapper valve, one for heat control and the other for vapour or humidity control. All temperature variations are recorded graphically. 7. Diaphragm temperature control valve, air-operated. Among other uses the valve may be installed in an oil still, dyeing machine, tyre press, or pasteurization vat

within a metal tube) to which the instrument "head" with its graduated dial is directly attached. The great majority of applications, however, demand a *remote* bulb or thermocouple with either a closed system or an electrical system.

Closed Systems consist of bulb, capillary tube and Bourdon tube or capsular spring. They are either *completely* filled with mercury, another liquid or a gas; or *partially* filled with a volatile liquid the vapour pressure of which is utilized.

Electric Systems possess three advantages: (1) applicability to high temperature work, (2) practicability of long distance regulation, (3) replaceability of sensitive element. *Radiation Pyrometric Systems* are seldom used for automatic regulation. *Resistance Systems* are applicable for temperatures up to 300° F with base metal (nickel) elements and up to 1,500° F with platinum. *Thermoelectric Systems* may be of the galvanometric or potentiometric type. The latter has several advantages for "medium" temperatures. Usual range limitations are 300° to 1,800° F with base metal and 1,000° to 2,500° F with rare metal couples.

Other Conditions. *Pressure.*—The majority of pressure regulators are of the self-operating type, but for process work the air-operated type is being increasingly adopted. "Absolute pressure" and "differential pressure" regulators are in use in gas and by-product plants.

Humidity.—In general, instruments regulating the humidity in dryers consist of a pair of automatic temperature regulators of the closed system type—the bulb of one being affected by "air temperature" while the bulb of the other is enclosed in a constantly moistened porous sleeve exposed to the cooling effect of fairly rapid air circulation. The dry-bulb regulator unit controls the source of heat, while the wet-bulb unit controls the "spray." Many ingenious humidity regulators have recently appeared, including models which provide a "drying schedule."

Timing.—The first automatic regulators for this purpose were "modified alarm clocks." Modern ones dependably perform the complex cycles of operations required in vulcanization, dyeing, pasteurization of milk, etc. (*See* ROBOTS.)

Liquid Level.—An "automatic liquid level regulator" is to be found in every modern bathroom, but the industrial types necessarily differ. They utilize auxiliary power to operate large valves. Extra heavy and corrosion-resisting models are used in petroleum refineries and chemical plants under severe temperature and pressure conditions.

Flow.—While flow meters are being increasingly adopted in power plants and numerous industries, the demand for automatic regulation of flow has not as yet brought about the full development of special instruments.

Specific Gravity.—Two types of devices which automatically regulate the density of the substance being processed are commercially manufactured. One utilizes the hydrometric principle and embodies a float chamber; the other utilizes the electrical resistance of the substance being processed.

Speed.—Standardized commercial devices consist essentially of tachometers provided with electric contacts or other means of operating levers, rheostats or other appliances.

See *The Instrument World* (London) and *Instruments* (Pittsburgh, Pa.). (M. F. BÉ.)

REGULUS, MARCUS ATILIUS, Roman general and consul (for the second time) in the ninth year of the First Punic War (256 B.C.). He was one of the commanders in the naval expedition which shattered the Carthaginian fleet at Ecnomus, and landed an army on Carthaginian territory (*see* PUNIC WARS).

The other consul was recalled, Regulus being left behind to finish the war. After a severe defeat at Adys near Carthage, the Carthaginians were inclined for peace, but the terms proposed by Regulus were so harsh that they resolved to continue the war. In 255, Regulus was completely defeated and taken prisoner by the Spartan Xanthippus. There is no further trustworthy information about him. According to tradition, he remained in captivity until 250, when after the defeat of the Carthaginians at Panormus he was sent to Rome on parole to negotiate a peace or exchange of prisoners. On his arrival he strongly urged the senate to refuse both proposals, and returning to Carthage was tortured to death (Horace, *Odes,* iii. 5). The story is insufficiently attested; it may have been invented to excuse the treatment of Carthaginian prisoners at Rome but it served to make Regulus the type of heroic endurance to the later Romans.

See Polybius i. 25–34; Florus ii. 2; Cicero, *De Officiis,* iii. 26; Livy, *Epit.* 18; Valerius Maximus ix. 2; Sil. Ital. vi. 299–550; Appian, *Punica,* 4; Zonaras viii. 15; *see* also O. Jäger, *M. Atilius Regulus* (1878).

REHAN, ADA (1860–1916), American actress, whose real name was Crehan, was born in Limerick, Ireland, on April 22, 1860. Her parents removed to the United States when she was five years old. She made her first stage appearance in *Across the Continent* at Newark (N.J.), in 1874. She was with Mrs. John Drew's stock company in Philadelphia, John W. Albaugh's in Albany and Baltimore, and other companies for several seasons, playing a variety of minor parts, until she became connected with Augustin Daly's theatrical management in 1879. Under his training she soon showed her talents for vivid, charming portrayal of character in modern and older comedies.

She was the heroine in all the Daly adaptations from the German, and added to her triumphs the parts of Peggy in Wycherly's *Country Girl,* Julia in the *Hunchback,* and especially Katharina in *The Taming of the Shrew,* besides playing Rosalind and Viola. Miss Rehan accompanied Daly's company to England (first in 1884), France and Germany (1886). She died in New York city, on Jan. 8, 1916.

REHOBOAM, son and successor of king Solomon (*q.v.*), began to reign *c.* 937 B.C. He was not acceptable to the northern tribes of Israel, who recalled Jeroboam from his exile in Egypt and made Rehoboam's contemptuous refusal of their demands the occasion for instituting a rival kingdom under Jeroboam (1 Kings xii.). It is probable that this was done with the encouragement of Egypt. Shishak of Egypt attacked the kingdom of Judah *c.* 930, and despoiled the temple at Jerusalem of its treasures. Rehoboam's reign was marked by constant conflict with the kingdom of Israel. An unfavourable judgment is pronounced on him by the editor of Kings because he favoured customs connected with Baal worship. The fact that his mother was an Ammonitess may in some measure account for this. He was succeeded after a reign of 17 years by his son Abijah (in I Kings, Abijam) of whom little is known save a victory over Jeroboam.

REICHENAU, a picturesque island in the Untersee or western arm of the lake of Constance, 3 m. long by 1 broad, and connected with the east shore by a causeway three-quarters of a mile long. It belongs to the Republic of Baden. It had 2,055 inhabitants in 1925. The soil is very fertile, and excellent wine is produced in sufficient quantity for exportation. The Benedictine abbey of Reichenau, founded in 724, was long celebrated for its wealth and for the services rendered by its monks to the cause of learning. In 1540 the abbey, which had previously been independent, was annexed to the see of Constance, and in 1799 it was secularized. The abbey church, dating in part from the 9th century, contains the tomb of Charles the Fat (d. 888), who retired to this island in 887, after losing the empire of Charlemagne.

REICHENBACH, a town in the Prussian province of Silesia, situated on the Peile, at the foot of the Eulengebirge, a spur of the Riesengebirge, 30 m. S.W. of Breslau by rail. Pop. (1925) 16,093. Among its industries are dyeing, brewing and machine building and the manufacture of chemicals and glass buttons, and there is a considerable trade in grain and cattle. Here was held, in 1790, the congress which resulted in the convention of Reichenbach—between Great Britain, Prussia, Austria, Poland and Holland—guaranteeing the integrity of Turkey. Here, too, in 1813, was signed the treaty for the prosecution of the war against France.

REICHENBACH, a town in the republic of Saxony, situated in the Vogtland, 11 m. S.W. of Zwickau, at the junction of the main lines of railway Dresden-Leipzig-Hof. Pop. (1925) 30,862. The earliest mention of the town occurs in a document of 1212. The woollen manufacture was introduced in the 15th century, and took the place of the mining industry. The industries include the manufacture of textile goods and machinery and dyeing.

REICHENBERG: *see* LIBEREC.

REICHENHALL, a town in the republic of Bavaria, on the river Saalach, 1,570 ft. above sea-level, 9 m. S.W. of Salzburg Pop. (1925) 8,274. The brine springs of Reichenhall are mentioned in a document of the 8th century and were perhaps known to the Romans; but almost all trace of antiquity of the town was destroyed by a conflagration in 1834. The brine conduit to Traunstein dates from 1618. The water of some of the springs, the sources of which are 50 ft. below the surface, is so strongly saturated with salt (up to 24%) that it is at once conducted to the boiling houses, while that of the others is first submitted to a process of evaporation. Reichenhall is the centre of the four chief Bavarian salt-works: Berchtesgaden, Traunstein and Rosenheim. Reichenhall has become within the last century an important health-resort.

REICHSBANK. The Reichsbank is the central bank of Germany, corresponding to the Bank of England. It was founded in 1875, following upon the unification of the German empire. Under its original constitution, its management was divided between its shareholders, acting through a committee, and the Government, but the latter exercised the real control.

In considering the pre-war duties and functions of the Reichsbank, it must be remembered that it did not "grow up" like the Bank of England, but was founded as part of the set scheme of the German empire. Hence the close control exercised by the State, and hence the fact that it assumed certain duties which in England were performed by other organisms.

The chief points of difference were: (*a*) that the Reichsbank did not confine itself to being a bankers' bank; and (*b*) it performed the functions of the London provincial bankers' clearing houses. From these two points follows the fact that the Reichsbank had as many as 400 to 500 offices and agencies situated in every part of the empire, and was also accustomed to discount paper which did not invariably possess the standing required in London by the Bank of England.

The "giro" or clearing system was based on that of the Hamburg clearing house, which was absorbed by the Reichsbank on its foundation. The clearing system of the Bank of Prussia was taken over a year later. Clients, who might be other banks or private individuals, had to maintain a minimum "giro" balance with the Reichsbank, which, in 1913, averaged mks.25,000, and could then have money due to them paid in by their debtors at any office of the Reichsbank and remitted to their credit free of charge. This system was inaugurated with the deliberate object of facilitating trade, and its success is measured by the fact that 1913 witnessed 26·5 million "giro" entries in the books of the Reichsbank. It must be remembered that during the last century, cheques in Germany were hardly in use. Hence the need for this system.

Prior to 1871, the note issue was in the hands of various State and private banks. Political and other considerations made it unwise to attempt to suppress these, but the Reichsbank was given the right of issue, and its notes eventually outweighed in number and importance those of other banks. As has happened in England, some private banks allowed their right of issue to lapse, and immediately prior to the war, only five banks were entitled to issue notes beyond the limits of their gold cover. These were:—

Reichsbank could issue, uncovered, mks. . . .	470,000,000
Bank of Saxony could issue, uncovered, mks. . .	17,000,000
Bank of Bavaria could issue, uncovered, mks. . .	32,000,000
Bank of Würtemburg could issue, uncovered, mks. .	10,000,000
Bank of Baden could issue, uncovered, mks. . .	10,000,000
Mks.	539,000,000

The predominance of the Reichsbank is apparent.

The Reichsbank was in theory bound to redeem its notes in gold on demand, but in practice it discouraged applications. This was a matter of national policy, as the Government was continually adding to the country's gold stocks in preparation for future events.

The existence of a fixed limit to the fiduciary issue of 470 million marks placed the Reichsbank in a similar position to the Bank of England (*q.v.*) under Peel's Act of 1844. There was, however, one vital point of distinction. The Bank of England could not exceed the limit without special authority from the Government, and so only did so four times in the 70 years 1844–1914. The Reichsbank could always exceed its limit on payment of a five per cent. tax on the excess issue, and so habitually did so as a matter of course.

Reichsbank and the World War.—On the outbreak of war in 1914, the Reichsbank obligation to redeem notes in gold and its liability to tax on its excess note issue were suspended, while Treasury bills and bonds, with less than three months to run, were authorized to be used as cover to the note issue. (Cover was originally limited to Treasury notes redeemable in cash on demand, notes of the issuing banks which were allowed to be reckoned as specie and bills carrying at least two good names and maturing within three months.) A vigorous propaganda was instituted to concentrate gold in the hands of the Reichsbank, and this met with some measure of success. On the other hand, the bank was bound to discount such Treasury bills and bonds as the State required it to, and to issue notes against them. This was the method by which currency inflation was carried out in Germany.

Dr. Schacht, in his book *The Stabilisation of the Mark*, states that the war inflation was such as to raise the *per capita* note circulation from mks.110 to mks.430. The history of the post-war inflation period is told elsewhere (*see* CURRENCY; GERMANY; MARK), but for the first few years the Reichsbank was under the control of the Government, and had to discount such Treasury bills as were presented to it and to issue notes against them. The amendment of the Bank Law of July 8, 1926, authorizes the Bank to discount Treasury bills of the Reich with a maturity of not more than three months, and to grant advances against such bills up to 400,000,000 Reichsmarks.

In 1922 the Reichsbank was freed by legislation from Government control and so gained its nominal independence. For a few months it tried to arrest the fall in the mark, but the pressure of events was too much for it. The occupation of the Ruhr in early 1923 gave the mark its death-blow.

During most of 1923, the Reichsbank was perforce a passive spectator of the general collapse, and the first step to recovery, namely the institution of the Rentenmark, was taken by an organization nominally independent of the Reichsbank. Later on the Reichsbank was able to take definite and decisive action. At the end of 1923, it forced the Government to abandon its policy of ceaseless borrowing from the bank by the discount of Treasury bills; in early 1924, under the presidency of Dr. Schacht, it promoted the establishment of the Gold Discount Bank; and in April 1924, it put into force a general rationing of credit. (*See* MARK.)

Reconstitution of 1924.—During these months, the Dawes commission was at work, and among its duties was that of the reconstitution of the Reichsbank. In effecting this, the Dawes commission had two objects. One was the economic reconstruction of Germany, and the other was the organization of adequate reparations payments. As regards the last, the scheme was for the German Government to pay the sums due into the accounts held by the agent-general for reparations at the Reichsbank, for him in his turn to transfer to the recipient nations in such amounts and at such times as the state of the foreign exchanges permitted.

This second objective had a marked effect upon the new constitution of the Reichsbank. Foreign control was clearly necessary, and yet due regard had to be paid to German claims. Dr. Schacht gives in his book a very clear account of the negotiations. In sum, a council was set up, composed of an equal number of German and foreign representatives. This had certain powers, including the appointment of the directors of the bank, who exercised the executive control. These last, however, had to be Germans, and the president had to have his appointment confirmed by the president of the State. In case of dead-lock, the president could reject the first two nominees of the council, but the third choice of the council could be appointed over his head.

The new note issue was based on the American ratio system, and the relation between the various notes was fixed at 1 new Reichsmark=1 Rentenmark=1,000,000,000,000 old marks. The right of the Reichsbank to issue notes was extended from 10 to

50 years, during which period the State could not abrogate it. Of the note issue 40% had to be covered by gold or "gold exchange" (30% to be gold), and this cover was provided initially by the German loan floated internationally in the autumn of 1924. Furthermore, 40% of deposits had to be covered by "liquid assets," such as short-term bills. The compulsory redemption by the bank of notes in gold was postponed pending a general return by other nations to the gold standard.

Issue of uncovered notes beyond the 40% ratio is permitted, subjected to a graduated tax on the excess and regulations as to the bank's discount rate. If by the issue of additional notes the ratio falls to 37–40%, the tax is 3%; between 35 and 37%, 5%; and between 33⅓ and 35%, 8%, rising by a point for every point fall below 33⅓%. The discount rate must be at least 5%, rising above this by at least one-third of tax payable. Other provisions included the organisation of the State's debt to the bank, the reduction and fixation of the bank's capital, the allocation of profits between the shareholders and the State, and the retirement of Rentenmark and other temporary notes. The independence of the bank from the State is definitely maintained.

The new Bank law came into force on 11th October, 1924. The subsequent history of the Reichsbank is part of the general economic history of Germany (*q.v.*). It is sufficient to add that the Reichsbank has played its part in the economic resettlement of the world. (N. E. C.)

REICHSTADT, NAPOLEON FRANCIS JOSEPH CHARLES, DUKE OF (1811–1832), known by the Bonapartists as Napoleon II., was the son of the Emperor Napoleon I. and Marie Louise, archduchess of Austria. He was born on March 20, 1811, in Paris at the Tuileries palace. He was at first named the king of Rome, after the analogy of the heirs of the emperors of the Holy Roman Empire. By his birth the Napoleonic dynasty seemed to be finally established; but in three years it crumbled in the dust. At the time of the downfall of the empire (April 1814) Marie Louise and the king of Rome were at Blois with Joseph and Jerome Bonaparte, who wished to keep them as hostages. This design, however, was frustrated. Napoleon abdicated in favour of his son; but events prevented the reign of Napoleon II. from being more than titular. While Napoleon repaired to Elba, his consort and child went to Vienna; and they remained in Austria during the Hundred Days (1815), despite efforts made by the Bonapartists to carry off the prince to his father at Paris. In the settlements of 1814 and 1815 (*see* MARIE LOUISE)—the powers opposed all participation of the prince in the affairs of his mother's duchy of Parma. He therefore remained at Vienna. From this time onward he became, as it were, a pawn in the complex game of European politics, his claims being put forward sometimes by Metternich, sometimes by the unionists of Italy, while occasionally malcontents in France used his name to discredit the French Bourbons. In November 1816 the court of Vienna informed Marie Louise that her son could not succeed to the duchies. This decision was confirmed by the treaty of Paris of June 10, 1817. The title of "duke of Reichstadt" was conferred on him on July 22, 1818 by way of compensation. Thus Napoleon I., who once averred that he would prefer that his son should be strangled rather than brought up as an Austrian prince, lived to see his son reduced to a rank inferior to that of the Austrian archdukes.

His education was confided chiefly to Count Dietrichstein, who found him precocious, volatile, passionate and fond of military affairs. His nature was sensitive, as appeared on his receiving the news of the death of his father in 1821. The upheaval in France in 1830 and the disturbances which ensued led many Frenchmen to turn their thoughts to Napoleon II.; but though Metternich dallied for a time with the French Bonapartists, he had no intention of inaugurating a Napoleonic revival. The duke's indulgence in physical exercise far beyond his powers aggravated a natural weakness of the chest, and he died on July 22, 1832.

REID, SIR GEORGE (1841–1913), knighted in 1902, Scottish artist, was born in Aberdeen on Oct. 31, 1841. He was apprenticed in 1854 for seven years to Messrs. Keith & Gibb, lithographers in Aberdeen. In 1861 Reid took lessons from an itinerant portrait-painter, William Niddrie, who had been a pupil of James Giles, R.S.A., and afterwards entered the school of the Board of Trustees in Edinburgh. His first portrait of interest was that of George Macdonald, the poet and novelist, now the property of the university of Aberdeen. In 1865 he went to Utrecht to study under A. Mollinger, whose work he admired for its unity and simplicity. For some years after this his work failed to please the Scottish authorities, but after his further studies under Yvon in Paris and Josef Israëls at The Hague, Reid's success was assured. A typical landscape is his "Whins in Bloom," which combines great breadth with fine detail. His flower-pieces, such as "Roses," were brilliant, but his most individual work is found in his portraits, which show great insight.

REID, SIR GEORGE HOUSTON, K.C.M.G., 1909 (1845–1918), Australian politician, was born on Feb. 25, 1845, at Johnstone, Renfrewshire, and emigrated in 1852 to Australia. He practised as a barrister in Sydney and was elected to the New South Wales parliament in 1880. In 1883–84 he was minister of public instruction and from 1891–94 was leader of the free trade party. In 1894 he became premier and retained office until 1899. Reid played a conspicuous part in the federation movement and was a member of the first Commonwealth parliament in 1901, leading the free trade opposition to Sir Edmund Barton. In 1904 he became Prime Minister, but he stood for a programme which was unacceptable to a predominantly protectionist country, and after his fall in the following year he never again held office. He led the opposition from 1905–08 and in the latter year retired from Australian politics. In 1909 he was appointed high commissioner in London; and on the expiration of his term entered the House of Commons as Conservative member for St. George's, Hanover Square, London. He published *My Reminiscences* in 1917. He died on Sept. 12, 1918.

REID, ROBERT (1862–), American artist, was born at Stockbridge (Mass.), on July 29, 1862. He studied at the art schools of the Boston Museum of Fine Arts, the Art Students' League, New York, and under Boulanger and Lefebvre in Paris. His early pictures were figures of French peasants, painted at Étaples, but subsequently he became best known for mural decoration and designs for stained glass. He contributed with others to the frescoes of the dome of the Liberal Arts Building at the Columbian Exposition, Chicago, in 1893. Other work is in the Congressional Library, Washington, the Appellate Court House, New York, and the State House, Boston, where are his three large panels, "James Otis Delivering his Speech against the Writs of Assistance," "Paul Revere's Ride," and the "Boston Tea Party." He executed a panel for the American pavilion at the Paris Exhibition, 1900, and in 1906 he completed a series of ten stained glass windows for a church at Fairhaven (Mass.), for the Rogers memorial. In 1906 he became a full member of the National Academy of Design. He is a member of the National Institute of Arts and Letters and of the Ten American Painters.

REID, SIR ROBERT GILLESPIE (1840–1908), Canadian railway contractor, was born at Coupar-Angus, Scotland. When a young man he spent a few years in Australia gold-mining, and in 1871 he settled in America, where he began his career as a contractor. He built one section of the Canadian Pacific railway, and was responsible for the erection of the international bridge over the Niagara river, the international railway bridge over the Rio Grande river and the Lachine bridge over the St. Lawrence. In 1893 Reid signed a contract with the government of Newfoundland by which he undertook to construct a railway from St. John's to Port-aux-Basques and to work the line for ten years in return for a large grant of land. In 1898 he further contracted to work all the railways in Newfoundland for 50 years on condi-

tion that at the end of this time they should become his property. This bargain, which included other matters such as steamers, docks and telegraphs, was extraordinarily favourable to Reid, who, by further enormous grants of land, became one of the largest landed proprietors in the world; public opinion was aroused against it, and eventually the terms of the contract were revised, being made more favourable to Newfoundland, and Reid's interests were transferred to a company, the Reid Newfoundland Company, of which he was the first president (*see* NEWFOUNDLAND, *Roads and Railways*). Reid was knighted in 1907. He died on June 3, 1908.

REID, THOMAS (1710–1796), the founder of the "Scottish School" of philosophy, was born on April 26, 1710, at Strachan in Kincardineshire, where his father was minister. He graduated at Aberdeen in 1726, remained there as librarian for ten years, and was presented to the living of Newmachar near Aberdeen in 1737. His first philosophical work, *Essay on Quantity, occasioned by reading a Treatise in which Simple and Compound Ratios are applied to Virtue and Merit,* denying the possibility of mathematical treatment of moral subjects, appeared in the *Transactions* of the Royal Society (1748). In 1740 Reid married a cousin, the daughter of a London physician. In 1752 he became professor of philosophy at King's college, Aberdeen. The Aberdeen Philosophical Society (the "Wise Club"), which numbered among its members Campbell, Beattie, Gerard and Dr. John Gregory, was mainly founded by Reid, who was secretary for the first year (1758). Reid propounded his point of view in the *Enquiry into the Human Mind on the Principles of Common Sense* (1764). In this year, Reid succeeded Adam Smith as professor of moral philosophy at Glasgow.

After 17 years he retired to complete his philosophical system. The *Essays on the Intellectual Powers of Man* appeared in 1785, and their ethical complement, the *Essays on the Active Powers of the Human Mind,* in 1788. These, with an account of Aristotle's *Logic* appended to Lord Kames's *Sketches of the History of Man* (1774), conclude the list of works published in Reid's lifetime. He died of paralysis on Oct. 7, 1796.

The key to Reid's philosophy is to be found in his revulsion from the sceptical conclusions of Hume. In several passages of his writings he expressly dates his philosophical awakening from the appearance of the *Treatise of Human Nature.* In the dedication of the *Enquiry,* he says: "The ingenious author of that treatise upon the principles of Locke—who was no sceptic—hath built a system of scepticism which leaves no ground to believe any one thing rather than its contrary. His reasoning appeared to me to be just; there was, therefore, a necessity to call in question the principles upon which it was founded, or to admit the conclusion." Having decided that the rationalist philosophy was subversive of religion and morals he examined the doctrine, which he declared to be contrary to experience. He appealed not to eternal truths, but to the testimony of experience. He maintained that we do not start with "ideas," and afterwards refer them to objects; we are never restricted to our own minds, but are from the first immediately related to a permanent world. There are certain presuppositions unassailable by doubt which are older and more authoritative than any philosophy. Among these he places the belief in a material external world and in the existence of the soul. Reid has a variety of names for the principles which, by their presence, lift us out of subjectivity into perception. One of these, "principles of common sense," which became the current one, conveyed a false impression of Scottish philosophy. Reid did not merely appeal from the reasoned conclusions of philosophers to the unreasoned beliefs of common life. His real mode of procedure is to redargue Hume's conclusions by a refutation of the premises inherited by him from his predecessors. Reid everywhere unites common sense and reason, making the former "only another name for one branch or degree of reason." Reason, as judging of things self-evident, is called common sense to distinguish it from ratiocination or reasoning. And in regard to Reid's favourite proof of the principles in question by reference to "the consent of ages and nations, of the learned and unlearned," it is only fair to observe that this argument assumes a much more scientific form in the *Essays,* where it is almost identified with an appeal to "the structure and grammar of all languages." "The structure of all languages," he says, "is grounded upon common sense." To take but one example, "the distinction between sensible qualities and the substance to which they belong, and between thought and the mind that thinks, is not the invention of philosophers; it is found in the structure of all languages, and therefore must be common to all men who speak with understanding" (Hamilton's *Reid,* pp. 229 and 454).

BIBLIOGRAPHY.—The best edition of Reid's *Works* is that by Sir William Hamilton (2 vols.). *See* also "Reid and the Philosophy of Common Sense" in J. F. Ferrier's *Lectures,* ed. Grant and Lushington (1866); A. C. Fraser, *Thomas Reid* ("Famous Scots Series," 1898); K. Peters, *Thomas Reid als Kritiker von David Hume* (Leipzig, 1909); O. M. Jones, *Empiricism and Intuitionism in Reid's Common Sense Philosophy* (1927).

REID, THOMAS MAYNE (1818–1883), better known as MAYNE REID, British novelist, the son of a Presbyterian minister, was born at Ballyroney, Co. Down, Ireland, on April 4, 1818. His own early life was as adventurous as any boy reader of his novels could desire. When 20 years old he went to America in search of adventure. He traded on the Red river, studying the ways of the red man and the white pioneer; he made acquaintance with the Missouri in the same way. In Philadelphia, where he was engaged in journalism from 1843 to 1846, he made the acquaintance of Edgar Allan Poe. When the war with Mexico broke out in 1846 he obtained a captain's commission, was present at the siege and capture of Vera Cruz, and led a forlorn hope at Chapultepec, where he sustained such severe injuries that his life was despaired of. In one of his novels he says that he believed theoretically in the military value of untrained troops, and that he had found his theories confirmed in actual warfare. He offered his services to the Hungarian insurgents in 1849, raised a body of volunteers, and sailed for Europe, but arrived too late. He then settled in England, and began his career of a novelist with the publication, in 1850, of the *Rifle Rangers.* This was followed next year by the *Scalp Hunters.* He never surpassed his first productions, except perhaps in *The White Chief* (1859) and *The Quadroon* (1856); but he continued to produce tales of self-reliant enterprise and exciting adventure with great fertility. He died in London on Oct. 22, 1883.

See *Memoir* (1890) by his widow, Elizabeth Mayne Reid.

REID, WHITELAW (1837–1912), American journalist and diplomatist, was born of Scotch parentage, near Xenia, O., on Oct. 27, 1837. He graduated at Miami University in 1856, and spoke frequently in behalf of John C. Frémont, the Republican candidate for the presidency in that year. In 1860 he became legislative correspondent at Columbus for several Ohio newspapers, including the Cincinnati *Gazette,* of which he was made city editor in 1861. He was war correspondent for the *Gazette* in 1861–62, serving also as volunteer aide-de-camp to generals Thomas A. Morris, William S. Rosecrans in West Virginia, and was Washington correspondent of the *Gazette* in 1862–68. In 1868 he became a leading editorial writer for the New York *Tribune,* in the following year was made managing editor, and in 1872, upon the death of Horace Greeley, became the principal proprietor and editor-in-chief. In 1905 Reid relinquished his active editorship of the *Tribune,* but retained financial control. He served as minister to France in 1889–92, and in 1892 was the unsuccessful Republican candidate for vice president on the ticket with Benjamin Harrison. In 1897 he was special ambassador of the United States on the occasion of Queen Victoria's jubilee; in 1902 was special ambassador of the United States at the coronation of King Edward VII., and in 1905 became ambassador to Great Britain. In 1881 he married a daughter of Darius Ogden Mills (1825–1910), a prominent financier. He died in London on Dec. 15, 1912.

His publications include *After the War* (1867); *Ohio in the War* (1868); *Some Consequences of the Last Treaty of Paris* (1899); *Our New Duties* (1899); *Later Aspects of Our New Duties* (1899); *Problems of Expansion* (1900); *The Greatest Fact in Modern History* (1906); *How America Faced its Educational Problem* (1906); *The Scot in America and the Ulster Scot* (1912), and posthumously, *American and English Studies* (1913).

See Royal Cortissoz, *The Life of Whitelaw Reid* (1921).

REIDSVILLE, a town of Rockingham county, North Carolina, U.S.A., in the northern part of the State, at an altitude of 822 ft.; on the Southern railway and Federal highway 170, 20 m. S.W. of Danville, Va. Pop. 5,333 in 1920 (37% negroes); estimated locally at over 7,800 in 1928. It is an important tobacco-shipping point, and has cotton and silk mills, and factories making 60,000,000 cigarettes daily. The town was founded about 1860 and incorporated in 1873. It has a commission-manager form of government.

REIGATE, a market town and municipal borough in Surrey, England, 24 m. S. by W. of London by the S.R. Pop. (1921) 28,914. Reigate (*Cherchefelle, Regat, Reygate*), at a cross-road on the Pilgrim's Way, at the foot of the North Downs, had a castle, a stronghold of the De Warennes in the 12th, 13th and 14th centuries. On the death of Edith, the widow of Edward the Confessor, to whom it belonged, William I. secured the manor of Cherchefelle, as it was then called. It was granted by William Rufus to Earl Warenne, through whose family it passed in 1347 to the earls of Arundel. The name Reigate occurs in 1199. Burgesses of Reigate are mentioned in a close roll of 1348, but no early charter is known. The town was incorporated in 1863. It returned two members to parliament from 1295 till 1831, and afterwards one member only until 1867, when it was disfranchised for corruption. It is situated at the head of the long valley of Holmsdale Hollow. Of the old castle built before the Conquest, there only remains the entrance to a cave beneath, 150 ft. long and from 10 to 12 ft. high, excavated in the sandstone, which was used as a guardroom. The grounds are laid out as a public garden. Near the market house is the site of an ancient chapel dedicated to Thomas à Becket. In the chancel of the parish church of St. Mary (Transitional Norman to Perpendicular) is buried Lord Howard, the commander of the English navy against the Spanish Armada. Above the vestry is a library containing manuscripts and rare books. The grammar school was founded in 1675.

REIMARUS, HERMANN SAMUEL (1694–1768), German philosopher and man of letters, was born at Hamburg, on Dec. 22, 1694. He was educated by his father and by the famous scholar J. A. Fabricius, whose son-in-law he became, and later at Jena. He was professor of Hebrew and Oriental languages in the high school of his native city from 1727 till his death. His house was the centre of the highest culture, and a monument of his influence in that city still remains in the *Haus der patriotischen Gesellschaft,* where the learned and artistic societies partly founded by him still meet. He died on March 1, 1768.

Reimarus's reputation as a scholar rests on the valuable edition of Dio Cassius (1750–52) which he prepared from the materials collected by J. A. Fabricius. He also published *Abhandlungen von den vornehmsten Wahrheiten der natürlichen Religion* (Hamburg, 1754, 6th ed. 1791); *Vernunftlehre* (Hamburg and Kiel, 1756, 5th ed., 1790); *Betrachtungen über der Kunsttriebe der Thiere* (Hamburg, 1762, 4th ed., 1798). But his best-known work is his *Apologie oder Schutzschrift für die vernünftigen Verehrer Gottes* (carefully kept back during his lifetime), from which, after his death, Lessing published certain chapters under the title of the *Wolfenbüttel Fragments* (*see* LESSING). Other portions were published by "C. A. Schmidt" (1787) and D. W. Klose (1850–52). The original MS. is in the Hamburg town library.

The standpoint of the *Apologie* is that of pure naturalistic deism. Miracles and mysteries, with the exception of the Creation, are denied, and natural religion is put forward as the absolute contradiction of revealed. The essential truths of the former are the existence of a wise and good Creator and the immortality of the soul. These truths are discoverable by reason, and are such as can constitute the basis of a universal religion and lead to happiness. A revealed religion could never obtain universality, as it could never be intelligible and credible to all men.

See the "Fragments" as published by Lessing, reprinted in vol. xv. of *Lessing's Werke,* Hempel's edition; D. F. Strauss, *H. S. Reimarus und seine Schutzschrift für die vernünftigen Verehrer Gottes* (1862, 2nd ed., 1877); C. Voysey, *Fragments from Reimarus* (1879) (a translation of Strauss's book, with the second part of the seventh fragment, on the "Object of Jesus and his Disciples"); R. Schettler, *Die Stellung d. Philos. Reimarus zur Religion* (Leipzig, 1904), and J. Engert, *Reimarus als Metaphysiker* (Paderborn, 1909).

REIMS (RHEIMS), a city of north-eastern France, chief town of an arrondissement of the department of Marne, 98 m. E.N.E. of Paris, on the Eastern railway. Pop. (1926) 97,825. Reims stands in a plain on the right bank of the Vesle, a tributary of the Aisne, and on the canal which connects the Aisne with the Marne. South and west rise the "montagne de Reims" and vine-clad hills.

Before the Roman conquest Reims, as *Durocortorum,* was capital of the Remi, from whose name that of the town was subsequently derived. The Remi made voluntary submission to the Romans, and by their fidelity secured the special favour of their conquerors. Christianity was established in the town by the middle of the 3rd century, at which period the bishopric was founded. The consul Jovinus, an influential supporter of the new faith, repulsed the barbarians who invaded Champagne in 336; but the Vandals captured the town in 406 and slew St. Nicasus, and Attila afterwards put it to fire and sword. Clovis, after his victory at Soissons (486), was baptized at Reims in 496 by St. Remigius. Later kings desired to be consecrated at Reims with the oil of the sacred phial which was believed to have been brought from heaven by a dove for the baptism of Clovis and was preserved in the abbey of St. Remi. Meetings of Pope Stephen III. with Pippin the Short, and of Leo III. with Charlemagne, took place at Reims; and here Louis the Débonnaire was crowned by Stephen IV. Louis IV. gave the town and countship of Reims to the archbishop Artaldus in 940. Louis VII. gave the title of duke and peer to William of Champagne, archbishop from 1176 to 1202 and the archbishops of Reims took precedence of the other ecclesiastical peers of the realm.

In the 10th century Reims had become a centre of intellectual culture, Archbishop Adalberon, seconded by the monk Gerbert (afterwards Pope Silvester II.), having founded schools where the "liberal arts" were taught. Adalberon was also one of the prime authors of the revolution which put the Capet house in the place of the Carolingians. The most important prerogative of the archbishops was the consecration of the kings of France—a privilege which was exercised, except in a few cases, from the time of Philip Augustus to that of Charles X. Louis VII. granted the town a communal charter in 1139. The treaty of Troyes (1420) ceded it to the English, who had made a futile attempt to take it by siege in 1360; but they were expelled on the approach of Joan of Arc, who in 1429 caused Charles VII. to be consecrated in the cathedral. A revolt at Reims, caused by the salt tax in 1461, was cruelly repressed by Louis XI. The town sided with the League (1585), but submitted to Henry IV. after the battle of Ivry. In the foreign invasions of 1814 it was captured and recaptured; in 1870–71 it was made by the Germans the seat of a governor-general and impoverished by heavy requisitions.

In the World War.—Reims suffered severely during the war of 1914–18. The town was heavily bombarded by the Germans in September 1914, and the population took shelter in the huge subterranean wine cellars, occupying old chalk quarries, where dormitories were made, schools were held, and a daily paper was published. In 1917 the civilian population which remained was evacuated; in 1918 the town was one of the objectives of the Germans, but it was held until freed by the allied offensive in October. Reims was then in ruins, and the cathedral was severely damaged, especially on the south-west side. The work of restoration of the cathedral, to the cost of which there was a large American contribution, took many years to complete. The statue of St. Joan of Arc, which stood in front of the cathedral, was removed during the war for safety, and replaced in 1921; many of the art treasures, tapestries, etc., were also saved.

The oldest monument in Reims is the Mars Gate (so called from a temple to Mars in the neighbourhood), a triumphal arch 108 ft. in length by 43 in height, consisting of three archways flanked by columns. It is popularly supposed to have been erected by the Remi in honour of Augustus when Agrippa made the great roads terminating at the town, but probably belongs to

the 3rd or 4th century. In its vicinity a curious mosaic, measuring 36 ft. by 26, with thirty-five medallions representing animals and gladiators, was discovered in 1860. To these remains must be added a Gallo-Roman sarcophagus, said to be that of the consul Jovinus and preserved in the archaeological museum in the cloister of the abbey of St. Remi.

The cathedral of Notre Dame, where the kings of France used to be crowned, replaced an older church (burned in 1211) built on the site of the basilica where Clovis was baptized by St. Remigius. The cathedral, with the exception of the west front, was completed by the end of the 13th century. That portion was erected in the 14th century after 13th-century designs—the nave having in the meantime been lengthened to afford room for the crowds that attended the coronations. In 1481 fire destroyed the roof and the spires. The façade was one of the most perfect masterpieces of the middle ages. The three portals are laden with statues and statuettes. The central portal, dedicated to the Virgin, was surmounted by a rose-window framed in an arch itself decorated with statuary. The rose-window, the statue of the smiling angel, the still more famous "Beau Dieu" statue were all severely damaged in the World War. The gallery of the kings above the rose-window survived but the angel spire was destroyed.

The archiepiscopal palace, built between 1498 and 1509, and in part rebuilt in 1675, was almost completely destroyed. The church of St. Remi (11th, 12th, 13th and 15th centuries) still retains intact its façade and two Romanesque towers; the nave and choir were ruined, and the mausoleum of St. Remigius (1847), containing the reliquary of the saint, behind the high altar, had to be reconstructed.

Reims is the seat of an archbishop, a court of assize and a sub-prefect, and a tribunal and a chamber of commerce. It is an important centre for the combing, carding and spinning of wool and the weaving of flannel, merino, cloth and woollen goods of all kinds. The manufacture of and trade in champagne are also very important. The wine is stored in large cellars tunnelled in the chalk. Other manufactures are linoleum, safes, capsules, bottles, casks, candles, soap and paper. The town is well known for its cakes and biscuits.

REINACH, JOSEPH (1856–1921), French author and politician, was born in Paris on Sept. 30, 1856. After leaving the Lycée Condorcet he was called to the bar in 1887. He attracted the attention of Gambetta by articles on Balkan politics published in the *Revue bleue*, and in Gambetta's *grand ministère* Reinach was his secretary. In the *République française* he waged a steady war against General Boulanger which brought him three duels, one with Edmond Magnier and two with Paul Déroulède. Between 1889 and 1898 he sat for the Chamber of Deputies for Digne. He brought forward many reform bills, advocated complete freedom of the theatre and the press, the abolition of public executions, and denounced political corruption. But he is best known as the champion of Captain Dreyfus. At the time of the original trial he attempted to secure a public hearing of the case, and in 1897 he allied himself with Scheurer-Kestner to demand its revision. He denounced in the *Siècle* the Henry forgery, and Esterhazy's complicity. His articles in the *Siècle* aroused the fury of the anti-Dreyfusard party, especially as he was himself a Jew and therefore open to the charge of bias. He lost his seat in the Chamber of Deputies, and, having refused to fight Henri Rochefort, eventually brought an action for libel against him. Finally, the "affaire" being terminated and Dreyfus pardoned, he undertook to write the history of the case, the first four volumes of which appeared in 1901. This was completed in 1905. In 1906 M. Reinach was re-elected for Digne. He died in Paris on April 18, 1921.

SALOMON REINACH (1858–), born at St. Germain-en-Laye on Aug. 29, 1858, brother of Joseph Reinach (*q.v.*), was educated at the École Normale Supérieure, and joined the French school at Athens in 1879. He made valuable archaeological discoveries at Myrina near Smyrna in 1880–82, at Cyme in 1881, at Thasos, Imbros and Lesbos (1882), at Carthage and Meninx (1883–84), at Odessa (1893) and elsewhere. He received in 1886 an appointment at the National Museum of Antiquities at St. Germain; in 1893 he became assistant keeper, and in 1902 keeper of the national museums. In 1903 he became joint editor of the *Revue archéologique*, and in the same year officer of the Legion of Honour. The lectures he delivered on art at the École du Louvre in 1902–3 were published by him under the title of *Apollo*.

His other works include: *Manuel de philologie classique* (1880–1884); *La Nécropole de Myrina* (1887), written with E. Pottier; *Répertoire de la statuaire grecque et romaine* (3 vols., 1897–98); *Répertoire de peintures du moyen âge et de la Renaissance 1280–1580* (1905, etc.); *Répertoire des vases peints grecs et étrusques* (1900). In 1905 he began his *Cultes, mythes et religions;* and in 1909 he published a general sketch of the history of religions under the title of *Orpheus.*

REINCARNATION, the belief that the soul after death returns to human life after a period of existence elsewhere, perhaps in animal or plant form or in some separate place, is found in many parts of the world. For an account of this doctrine in its social, religious and historical aspect see *Metempsychosis.*

REINDEER, a large Arctic and sub-Arctic deer, the American species of which is called caribou. The reindeer constitutes the genus *Rangifer,* characterized by the possession of antlers by both sexes, though those of the male are larger and more complex. Reindeer are clumsily built animals, with large lateral hoofs, hairy muzzles, and a curious type of antler with the brow-tine directed downwards. The compact, dense coat is clove-brown in colour above and white below, with a white tail-patch. The ears and tail are short and the throat is maned. A tarsal gland is present. The lateral metacarpal bones are represented only by their lower extremities (*see* DEER).

BY COURTESY OF THE N.Y. ZOOLOGICAL SOCIETY

REINDEER (RANGIFER TARANDUS) It inhabits arctic and sub-arctic regions

The type of the genus (*R. tarandus*) is the Scandinavian wild form. Two main distinct races, possibly species of the American form (*R. caribou*), are found—the woodland caribou, the largest of all reindeer, and the barren-ground caribou of the more northerly tundra, with a smaller body but larger antlers. The latter migrates south in huge herds at the approach of winter. A small species (*R. platyrhynchus*) inhabits Spitzbergen and Novaya Zembla. The reindeer has been domesticated by the Lapps and introduced as a domestic animal into Arctic Canada and Alaska. Reindeer feed largely on lichens, one species of which is the so-called "reindeer moss." It is a mistake to suppose that the brow-tine is used to scrape away snow; this is done with the hoofs, the horns being shed at the beginning of winter.

See M. Grant, "The Caribou," *7th Annual Report, New York Zoological Society* (1902); J. G. Millais, *Newfoundland and its Untrodden Ways* (1908).

REINDEER MOSS (*Cladonia rangiferina*), a species of lichen found in great abundance in Arctic lands. It is an erect, much branched plant, a few inches in height, which covers immense areas somewhat in the manner of pasture grasses in the temperate regions. In many districts it forms the chief food of the reindeer, and it also provides forage for the barren-ground caribou and the musk-ox. (*See* LICHENS.)

REINFORCED CONCRETE is a structural system utilizing fine concrete strengthened or reinforced in places by means of steel bars embedded within its mass. The concrete is so disposed as to resist the compressive or crushing stresses and form the general binding material while the steel bars act to prevent rupture at places where tension develops. The system is economical, durable and fire resisting and is adapted to an infinite variety of purposes in engineering and building construction. *See* FERRO-CONCRETE and CONCRETE.

REINFORCED GLASS: *see* GLASS, SAFETY.

REINHARDT, MAX (1873–), Austrian theatrical producer, was born in Raden, near Vienna, Austria, on Sept. 9, 1873. He was educated at the Untergymnasium, and then entered a

bank, where he remained until 17 years of age. He studied for the stage under Emil Burde, and in 1890 at the School of Acting of the Vienna Conservatorium. He began his professional career in 1893 at the Stadt theatre in Salzburg, where his characterization of elderly rôles attracted the attention of Otto Brahm, who engaged him for the Deutsches theater, Berlin, in 1894. There he met with notable success, creating such rôles as Baumert in Hauptmann's *The Weavers;* Akim in Tolstoy's *The Power of Darkness;* Engstrand in Ibsen's *Ghosts;* and many others. In 1903 he left the Brahm ensemble to begin his career as a director at the Neues theater, Berlin, with the production of Shakespeare's *A Midsummer Night's Dream,* in which he assumed leadership of the neo-romantic movement against the prevailing school of naturalism. He soon transferred his activities to the Deutsches theater, where, during the following years, he produced practically all the plays of Shakespeare, Molière, Goethe, Strindberg, Wedekind, Ibsen, Shaw and others, as well as musical comedies and operas, turning from the purely literary and historical conception of stage management to one essentially dramatic. In 1902, he opened his Kleines theater, and in 1906 his Kammerspielhaus. He was the first German producer to be invited to produce plays in foreign countries. Since 1909 he has given many productions in European cities, and in 1927–28 several notable ones in New York city. *See* Huntly Carter, *The Theatre of Max Reinhardt* (1914); *Max Reinhardt and His Theatre,* ed. Oliver M. Sayler (1924).

REINKENS, JOSEPH HUBERT (1821–1896), German Old Catholic bishop, was born at Burtscheid, near Aix-la-Chapelle on March 1, 1821. He became professor of ecclesiastical history at Breslau, and in 1865 rector of the university. In 1870, Reinkens opposed the proclamation of the dogma of papal infallibility. He signed the Declaration of Nüremberg in 1871, and took a conspicuous part in the Bonn conferences with the Orientals and Anglicans in 1874 and 1875. The Old Catholics having decided on secession, Reinkens was chosen their bishop in Germany at Cologne in 1873 (*see* OLD CATHOLICS). His best-known theological work is his treatise on Cyprian and the Unity of the Church (1873). In 1881 Reinkens visited England, and in 1894 he defended the validity of Anglican orders against his co-religionists, the Old Catholics of Holland. He died at Bonn on Jan. 4, 1896.

See *Joseph Hubert Reinkens,* by his nephew, J. M. Reinkens (Gotha, 1906).

REINSURANCE. Reinsurance is the term used to denote the transaction whereby a person who has insured a risk insures again a part or the whole of that risk with another person. The purpose of reinsurance is to relieve the original insurer from a liability which is too heavy for him to carry. There is no privity of contract between the reinsurer and the original insured, so that the latter could not sue the former to recover any part of a loss, but the insured could recover in respect of a loss against the original insurer up to the full amount of the policy, notwithstanding that part of it had been reinsured.

In a reinsurance transaction the company which reinsures is called the ceding company, the accepting company is called the reinsurer, and the transaction itself is termed a cession.

It is not known when reinsurance was first practised, though there is evidence of its existence at least as early as the first half of the 18th century. In the early days of insurance insurers did not, as a rule, insure for greater amounts than they were prepared to keep for themselves, and, even when this rule began to be relaxed, the arrangements whereby they relieved themselves of heavy commitments partook more of the nature of co-insurance than of reinsurance. Under such arrangements the original insured was in contractual relationship with each of the insurers.

However, in marine business reinsurance was known nearly 200 years ago, for in 1746 an act of parliament made it illegal, a prohibition which was not raised until 1864. It is thought by some that the Act of 1746 really prohibited double insurance; *i.e.,* where the insured covered his property twice, but the word used in the act is "reassurance." However this may be, it is certain that the growth of reinsurance in various sections of the business was slow until well into the 19th century, and it is only during the past 30 years or so that it has developed into its present important and widespread position.

Reinsurance may be divided into two main branches:—Facultative (or optional) and Treaty (or automatic or obligatory).

Facultative Reinsurance.—This was the original form. By this method each risk is offered for reinsurance separately and the ceding company has a free choice as to where it will offer the business. Similarly the reinsurer has freedom to accept or decline. The term facultative is derived from the power of choice, which this method implies. This system of reinsurance is cumbersome, as each risk reinsured has to be handled separately. The particulars of the risk are first shown to the reinsurer on a slip, which it initials for the share it is prepared to accept. This is followed by a request note; *i.e.,* a formal demand issued by the ceding company to the reinsurer for the specified reinsurance. Upon this the reinsurer issues its take note, which is its official acceptance given pending the issue of a reinsurance policy. This last is the final stage in the transaction, and forms the contract between the parties in respect of the risk reinsured.

The facultative system served its purpose at a time when insurance was transacted on a small scale, and when the need for reinsurance cover was neither great nor urgent. But the need arose in course of time for some more efficient method, and this was eventually found in the reinsurance treaty.

Reinsurance by Treaty.—A treaty is an obligatory arrangement, under which the ceding company binds itself to cede, and the reinsurer binds itself to accept, a fixed share of every risk, of a nature as defined in the contract, which the ceding company has to reinsure. A treaty, therefore, provides not for the reinsurance of an individual risk, but for all the risks of a given class. The power of choice is here eliminated. The two parties are reciprocally bound, one to cede and the other to accept.

This is an advantage to both, since the ceding company knows in advance that it can place the reinsurances and the reinsurer can rely on receiving a regular flow of business under the treaty. It is a condition of all treaties that, as soon as a reinsurance is placed thereunder the reinsurer's liability commences from the same moment as the liability of the ceding company, while the obligation to cede prevents the ceding company placing some of its reinsurances with one reinsurer and some with another, or favouring one at the expense of another. In both these particulars reinsurance by treaty differs from and represents a considerable advance over the older facultative method.

It is extremely rare for a ceding company to place a treaty with only one reinsurer, for this would be to entrust too great a responsibility to one undertaking. It is therefore customary to arrange a treaty so that a number of reinsurers share in it, each accepting only a proportionate part of the business ceded.

There are three kinds of reinsurance treaty in general use:—Quota-share or Open Treaties; Surplus Treaties; and Excess of Loss Treaties.

Quota-Share Treaty.—A quota-share treaty is one under which the ceding company agrees to cede a fixed share of every risk which it accepts from its clients. There is a necessary tendency for reinsurance business to comprise risks of a second class nature, since the better the risk the more the ceding company keeps for itself. But in a quota-share treaty this feature is not present. Every risk must be reinsured, whether it be good or bad, large or small. For this reason the quota-share treaty is not greatly used, except by small companies, which can obtain sound reinsurance cover only by offering attractive terms.

Surplus Treaty.—The surplus treaty is that in common use. Under this the ceding company first fixes the amount it will keep, which is called its retention, and the remainder of the amount insured constitutes the surplus. This is divided amongst the treaty reinsurers according to their due proportion. The whole surplus is usually divided into percentages, each reinsurer taking 1% or more as agreed of every surplus. But the amount which can be ceded is always governed by the ceding company's retention.

Excess of Loss Treaty.—An excess of loss treaty is an agreement under which no part of any individual risk is reinsured, but the ceding company arranges to cover only the excess of any one

loss over and above an agreed figure. This is a treaty to guard against catastrophe. A ceding company may arrange to cover itself by reinsurance against the excess of loss over £50,000 in respect of any one fire, the cover to run, say, up to £100,000; *i.e.*, a further £50,000. Then if one fire results in a loss to that company of £50,000, or less, the reinsurers pay nothing, but if the cost of the fire exceeds that figure the reinsurers pay the amount of the excess, according to their agreed proportions. This kind of treaty is largely used in motor insurance; but in fire insurance its use is a modern development. In that branch it is operated independently of and in addition to the surplus treaty. The ceding company must still use its surplus treaty to limit its liability on individual risks, taking out an excess of loss cover only to protect itself against heavy conflagrations.

Conditions of Reinsurance.—The conditions applying to a reinsurance are, as a rule, the same as those which apply to the original insurance. Thus the reinsurer receives the same rate of premium and must pay its proportionate share of any claim. There are, however, exceptions to this rule. Under an excess of loss treaty the reinsurer receives no specific premium, but is paid a percentage of the total premium income derived by the ceding company from the class of business to which the treaty applies. In marine reinsurance there is a practice to reinsure risks which are affected by a possibility of loss, and in such cases much higher premium may be paid than under the original policy.

The share of premium payable to the reinsurer is subject to a deduction of commission, which varies from 20% to 35% or, in rare cases, 40% or 45%. Reinsurance commission has to cover not only the agent's commission paid on the original insurance, but also a part of the ceding company's expense of obtaining and dealing with the business. The rate of reinsurance commission depends partly on the level of the expense of dealing with the business and partly on the quality of the treaty. Treaties giving consistently good results can command better terms than poor treaties. As well as commission deducted from premium, the reinsurer has to pay a commission—usually 10%—on the profits. In this way the profitable treaty automatically receives better terms than the bad one. The profit on a treaty is computed after making due provision for all claims and liabilities outstanding at the end of the year. The commission is payable on the average of the profit of the year of account, and of the two preceding years, so that a reinsurer shall not be required to pay away part of its profits in a year which follows a year showing a heavy loss.

The reinsurer, being liable to pay its share of all losses, is entitled to a like share of any amounts recovered as salvage. The ceding company has the control of all loss settlements and may settle a loss or contest a claim as it thinks fit. The reinsurer is bound to follow the fortunes of the ceding company in this matter.

Disputes arising between the parties to a reinsurance treaty, as to any matter coming thereunder, are almost invariably settled by arbitration.

Bordereaux.—Particulars of cessions made under a treaty are advised by the ceding company to the reinsurer by means of bordereaux. A bordereau is a statement giving the name and address of the insured, the nature of the risk, the sum insured, the premium, the amount reinsured and the reinsurance premium. No reinsurance policies are issued under treaties, as the reinsurance cover operates under the treaty contract. In marine business, however, properly stamped policies have to be issued even for reinsurance, under the provisions of the Stamp Act, 1891, and the Marine Insurance Act, 1906.

Retrocession.—A reinsurer, receiving particulars of its cessions by bordereaux, will itself deal with the business so received, and will in its turn arrange treaties to cede off its own surplus lines. A reinsurance of a reinsurance is called a retrocession. Retrocession is an important part of reinsurance business because where a reinsurer has a share of many treaties it will frequently receive a share of the same risk under many of its different treaties and must needs relieve itself by retrocession of the accumulation of risk. (C. E. G.)

United States.—The American reinsurance business has grown by leaps and bounds in the last two decades. For instance, according to the New York State Insurance reports on casualty insurance the ratio of reinsurance premiums to net premiums was 3·5% in 1915, while in 1925 the ratio was 8·3 per cent. As in the European countries Facultative and the three kinds of Treaty insurance are used, but the percentage of Facultative is rapidly diminishing because of delay and uncertainty.

What may be called a variation of the Fixed Treaty is the "Pool" or "Syndicate." Here as many as thirty-five companies will enter into an agreement to share all insurance in a given territory on a basis of certain agreed proportions both as regards premiums and losses. In order to facilitate the placing of reinsurance and to bring about greater uniformity of practice, reinsurance "Clearing Houses" or "Exchanges" have been established. Here the detailed reinsurance agreement is subscribed to by the member companies who are all represented by a manager. Many of the life insurance companies still use the Facultative plan of reinsurance. There are two ways of reinsuring. The smaller companies will reinsure the amount at risk with term insurance. Most of the larger companies use the "Coinsurance" plan, whereby the reinsurance company receives a proportionate part of the premium and guarantees a proportionate part of all payments including expenses and taxes. There are to-day many companies whose business is entirely reinsurance. (R. Ret.)

REISKE, JOHANN JACOB (1716–1774), German scholar and physician, was born on Dec. 25, 1716, at Zörbig in Electoral Saxony. From the Waisenhaus at Halle he passed in 1733 to the university of Leipzig, and there spent five years. He bought Arabic books, and when he had read all that was then printed he thirsted for manuscripts, and in March 1738 started on foot for Hamburg. At Hamburg he got money and letters of recommendation from the Hebraist Wolf, and took ship to Amsterdam. Reiske refused a generous offer from d'Orville at Amsterdam for his services as amanuensis. Ultimately he got free access to the Leiden collection, which he re-catalogued—the work of almost a whole summer, for which the curators rewarded him with nine guilders. D'Orville and Schultens helped him to find teaching and reading for the press. On the advice of Schultens he qualified as a doctor, after which, in 1746 he returned to Leipzig.

But he failed to secure any medical practice at Leipzig, and lived, as before, on ill-paid literary hack work. Although the electoral prince gave him the title of professor he was not permitted to lecture. At length in 1758 the magistrates of Leipzig rescued him from poverty by giving him the rectorate of St. Nicolai, and, though he still met with hostility in the university, he enjoyed the esteem of Frederick the Great, of Lessing, Karsten Niebuhr, and many foreign scholars. The last decade of his life was made cheerful by his marriage with Ernestine Müller, who shared all his interests and learned Greek to help him with collations. Reiske died on Aug. 14, 1774, and his ms. remains passed, through Lessing's mediation, to the Danish minister Suhm, and are now in the Copenhagen library.

Reiske surpassed all his predecessors in the range and quality of his knowledge of Arabic literature. In the *Adnotationes historicae* to his Abulfeda (*Abulf. Annales Moslemici*, 5 vols., Copenhagen, 1789–91), he collected a veritable treasure of sound and original research; he knew the Byzantine writers as thoroughly as the Arabic authors, and was alike at home in modern works of travel in all languages and in ancient and mediaeval authorities. He was interested too in numismatics, and his letters on Arabic coinage (in Eichhorn's *Repertorium*, vols. ix.–xi.) form, according to De Sacy, the basis of that branch of study.

In Leipzig Reiske worked mainly at Greek. His corrections are often hasty and false, but a surprisingly large proportion of them have since received confirmation from MSS. His German translations shew more practical insight than was usual in his time.

For a list of Reiske's writings *see* Meusel, xi. 192 *seq.* His chief Arabic works (all posthumous) have been mentioned above. In Greek letters his chief works are *Constantini Porphyrogeniti libri II. de ceremoniis aulae Byzant.*, vols. i. ii. (Leipzig, 1751–66), vol. iii. (Bonn, 1829); *Animadv. ad Graecos auctores* (5 vols., Leipzig, 1751–66) (the rest lies unprinted at Copenhagen); *Oratorum Graec. quae supersunt* (8 vols., Leipzig, 1770–73); *App. crit. ad Demosthenem* (3 vols., *ib.*,

1774–75); *Maximus Tyr.* (*ib.*, 1774); *Plutarchus* (11 vols., *ib.*, 1774–79); *Dionys Italic.* (6 vols., *ib.*, 1774–77); *Libanius* (4 vols., Altenburg, 1784–97). Various reviews in the *Acta eruditorum* and *Zuverl. Nachrichten* are characteristic and worth reading. Compare *D. Johann Jacob Reiskens von ihm selbst aufgesetzte Lebensbeschreibung* (Leipzig, 1783).

RÉJANE, GABRIELLE (CHARLOTTE RÉJU) (1857–1920), French actress, was born in Paris, the daughter of an actor. She was a pupil of Regnier at the Conservatoire, and took the second prize for comedy in 1874. Her *début* was made the next year, during which she played attractively a number of light—especially soubrette—parts. Her first great success was in Henri Meilhac's *Ma camarade* (1883), and she soon became known as an emotional actress of rare gifts, notably in *Décoré, Germinie Lacerteux, Ma cousine, Amoureuse* and *Lysistrata.* In 1892 she married Porel, the director of the Vaudeville theatre, but the marriage was dissolved in 1905. Her performances in *Madame Sans Gêne* (1893) made her as well known in England and America as in Paris, and in later years she appeared in characteristic parts in both countries, being particularly successful in *Zaza* and *La Passerelle.* She opened the Théâtre Réjane in Paris in 1906. The essence of French vivacity and animated expression appeared to be concentrated in Madame Réjane's acting, and made her unrivalled in the parts which she had made her own. She died in Paris on June 14, 1920.

REJANG, a tribe of Proto-Malayan or mixed Indonesian stock, partly akin to the Achinese, Bugis and Mangkassaras (*qq.v*). Though now Muslim they were formerly influenced by Indo-Javanese culture and retain an alphabet derived from that source, speaking a language of the Austronesian family. Their alphabet has been described as "pure Phoenician," but is intimately related to others derived from the Indo-Javan culture. Ideas of ancestor-worship are strong, and metempsychosis (*q.v.*) is vaguely believed in, tigers in particular being regarded as embodying the souls of the dead. Worship of the sea also prevails. It is believed that invulnerability can be acquired. Teknonymy is practised, and persons object to mentioning their own names. The dead are buried in a chamber excavated to one side of the grave. Betel is chewed. In blood-tariffs the value of a woman is nearly double that of a man except in the case of chiefs, only the highest of whom are rated higher than their wives.

See Marsden, *History of Sumatra* (1783). (J. H. H.)

REJERIA, the Spanish form of open-work screens made from combinations of wrought and cast iron work. The word *reja* is used for a screen, individually; *rejeria* properly signifies this whole class of iron work. A magnificent example is the *reja* of the Capilla Mayor of Seville cathedral (1518–33). Many beautiful examples of this type are found as window guards in Spanish Renaissance houses.

REJUVENATION. In all multicellular animals the process of regeneration, growth and rejuvenation is constant as is shown typically by the hair and nails. It is now possible to cultivate tissues in suitable media (*see* TISSUE CULTURE) and to keep them alive long after the death of the parent organism. This proves that death is not the inevitable end of cellular vitality, but is in every case the result of unfavourable conditions to which the cells are subjected at a given moment.

The endocrine glands produce substances (hormones), which they pour into the circulatory system and thereby influence the metabolic processes, the growth and morphology of the cells. One of these glands should have as its special function the secretion of a substance which gives tone and stimulus to cellular vitality during a certain period of life and ceases to do this on the approach of old age. This cannot be the special function of the thyroid, parathyroid, pituitary or suprarenal glands, since they continue to act during old age. The only gland which constitutes an exception to this rule is the genital gland. It plays a double rôle. It secretes spermatozoa externally, and it secretes internally hormones which it passes into the blood stream, actively at puberty and during maturity, but less and less thereafter, so that the diminution and disappearance of its activity correspond with old age.

Examination of male vertebrate animals, including man, after removal of the genital glands shows distinctly the nature of the influence of the internal secretion of these glands on the whole organism as affecting, not only the secondary male sexual characters, but also the growth and development of the body as a whole, the brain and skin cells, the bones and tissues. The physical and intellectual qualities of animals and of man are as intimately conditioned by the hormone secreted by the testicles as are the secondary sexual characters.

There can thus be no doubt as to the nature of the relation between the general reduction of the forces of the organism and the disappearance of the internal secretion of the testicles. No organ can keep its vital energy and yield a full return if the cells are not stimulated and vivified by the testicular hormone. It acts more or less directly on other endocrine glands, since castration is followed by hypertrophy of the anterior lobe of the pituitary gland and by regression of the thyroid body and epiphysis. If the genital glands remained active in old age, were they not the only glands which cease to secrete hormones, old age would certainly be delayed.

Eunuchs in Cairo who had been castrated at an early age and had therefore never been exposed to the activity of the testicular hormones, were never known to have been more than 60 at death. All had the appearance of old men, with desiccated skins, haggard eyes, bent, and looking like centenarians.

It is obvious that the deprivation of the internal secretion of the testicles accelerates the advance of old age and shortens life. The only remedy is to graft a young testicle, whether that of a young human being or of an ape, by which the tone-giving substance is provided, so as to increase the vitality of all the cells which are weakened but are not yet atrophied and therefore still able to renew themselves, and thus effectively to rejuvenate the whole organism. So long as an organism, however old, continues to exist, its cells continue to be renewed and rejuvenated. Unfortunately, in old age this process of rejuvenation is slowed down, a certain number of the functional cells regress and are replaced by conjunctive tissue. The cells which escape this are renewed more slowly, but continue to be renewed to the extreme limit of their vitality.

With a rich addition of the testicular hormone, the cells acquire new energy, grow more rapidly, proliferate more intensely and rejuvenate the whole system. At the end of several years the beneficent action of the grafted gland is exhausted because the grafts in turn are subject to positive regression. The organism is again deprived of the stimulating hormones and the symptoms of old age reappear. In most cases testicular grafting is adequate, but in some cases thyroid grafts have to be added. *See* S. Voronoff, *Rejuvenation by Grafting* (1925). (S. V.)

RELANDER, LAURI KRISTIAN (1883–), president of the republic of Finland, born May 31, 1883, and educated at Helsingfors university. He was a member of the central committee of the agrarian party in 1909, sat in the Diet from 1910 to 1913, and 1917–19, when he became its speaker. On Feb. 16, 1925, he was elected president of the republic.

RELAPSING FEVER (*Febris recurrens*), the name given to a specific infectious disease occasionally appearing as an epidemic in communities suffering from scarcity or famine. It is characterized mainly by its sudden invasion, with violent febrile symptoms, which continue for about a week and end in a crisis, but are followed after another week, during which the patient is fairly well, by a return of the fever. In exceptional cases, second, third and even fourth relapses may occur.

This disease has received many other names, the best known of which are famine fever, seven-day bilious relapsing fever, and spirillum fever. Like typhoid, relapsing fever was long believed to be simply a form of typhus. The distinction between them appears to have been first clearly established in 1826, in connection with an epidemic in Ireland.

In 1873 Obermeier discovered in the blood of persons suffering from relapsing fever minute spiral filaments of the genus *Spirochaete,* having rotatory or twisting movements. This organism received the name of *Spirillum obermeieri.* Fritz Schaudinn brought forward evidence that it is an animal parasite. Relapsing

fever is most commonly met with in the young. One attack does not appear to protect from others, but rather, according to some authorities, engenders liability. The incubation of the disease is about one week.

The mortality in relapsing fever is comparatively small, about 5% being the average death-rate in epidemics (Murchison). The fatal cases occur mostly from the complications common to continued fevers. The treatment is essentially the same as that for typhus fever. Löwenthal and Gabritochewsky by using the serum of an immune horse succeeded in averting the relapse in 40% of cases.

RELATIONSHIP TERMS. Relationship terms are studied by the anthropologist not merely as so many words inviting philological analysis and comparison, but as correlates of social custom. Broadly speaking, the use of a specific kinship designation, *e.g.*, for the maternal as distinguished from the paternal uncle, indicates that the former receives differential treatment at the hands of his nephews and nieces. Further, if a term of this sort embraces a number of individuals, the probability is that the speaker is linked to all of them by the same set of mutual duties and claims, though their intensity may vary with the closeness of the relationship. Sometimes the very essence of a social fabric may be demonstrably connected with the mode of classifying kin. Thus, kinship nomenclature becomes one of the most important topics of Social Organization.

In the daily routine of savage life, relationship terms are not only important as at once ticketing the status of the person addressed or mentioned with reference to the speaker, but also because often there is no other mode of address. This is because of the widespread prejudice against the vocative use of personal names, for which accordingly kinship appellations are substituted, even to the extent of assuming a relationship where none exists.

CLASSIFICATION OF KINSHIP TERMINOLOGIES

The foundation of the scientific study of this subject was laid by Lewis H. Morgan in his *Systems of Consanguinity and Affinity of the Human Family* (Smithsonian Contributions to Knowledge, XVII., Washington, 1871). In this great work were assembled comprehensive schedules for every major area of the globe except Africa and Australia, for which data were largely or wholly inaccessible to the author. Morgan grouped all terminologies under two main heads—the descriptive and the classificatory. The descriptive system, ascribed to the Aryan, Semitic and Uralian families, "describes collateral *consanguinei*, for the most part, by an augmentation or combination of the primary terms of relationship" (pp. 12, 468). The classificatory system never describes *consanguinei* by a combination of primary terms but ranges them into great classes or categories: "All the individuals of the same class are admitted into one and the same relationship, and the same special term is applied indiscriminately to each and all of them" (p. 143). Two varieties of the classificatory type were recognized—the Malayan, which merged all kindred of one generation irrespective of proximity in one category; and the Turanian-Ganowanian, in which only some of the collateral kin of a generation were merged with the lineal, the remainder being separated by distinctive terms.

This dichotomy is unacceptable. As Kroeber[1] and Rivers[2] remark, *our* words for uncle, aunt and cousin likewise range *consanguinei* into large classes, so that the absoluteness of the distinction breaks down. Furthermore, Rivers notes[3] that "descriptive" does not strictly apply to the English and related terminologies, which rarely augment or combine the primary terms. That epithet may be properly reserved for such Norwegian words as *farbror* and *morbror* for father's and mother's brother, respectively; and hence for certain nomenclatures, *e.g.*, the Arabic, which largely employ expressions of this order. Thus, Rivers supplanted Morgan's dualism with a tripartite scheme, recognizing denotative, descriptive and classificatory types. Elsewhere he suggests the appellations family, kindred and clan systems, the "kindred" being a major bilateral unit.[4] These latter terms are, however, objectionable since they inject the inferential basis of a system into its descriptive definition. There are clanless tribes with clan systems in Rivers' sense, and the result would be confusion. Apart from this terminological difficulty, the scheme fails to obviate a logical fault in Morgan's earlier effort. "Descriptive" and "classificatory" do not relate to the same logical universe, hence are not complementary terms. "Classificatory" relates to the number of individuals defined, "descriptive" to the technique of defining a relationship. It is possible to augment or combine primary terms and then apply the resultant to an indefinitely large class of persons. The antithesis to "classificatory" is the concept "individualizing," as Morgan felt, though he failed to express it.

But the purging of the traditional terminology does not carry us very far. How shall we characterize our simple English system if it embodies both individualizing *and* classificatory principles? The answer is provided in Kroeber's above-cited essay: a kinship terminology is not a logically coherent whole but must be resolved into the several categories recognized. Those enumerated by Kroeber are: the difference of generations; the difference between lineal and collateral kin; the difference of age within one generation; sex; the speaker's sex; the connecting relative's sex; the difference between consanguinity and affinity; and the life or death of the connecting relative.

This pioneer attempt requires both revision and amplification. The last mentioned feature, *e.g.*, is of purely local significance in western North America and of limited application where found. The differentiation between elder and younger sibling (brother *or* sister) means psychologically simply the intercalation of two additional generations. On the other hand, the reciprocity principle, linking by a common term distinct generations, merits independent status. Cognizance must also be taken of the frequent duplication of terms in address and mere reference, the mode of classification itself sometimes differing. Extra-American terminologies also suggest that the categories laid down by Kroeber might be materially increased. Even as it stands, however, his sketch furnishes a valuable instrument for the precise definition and comparison of distinct systems.[5]

In the present state of our knowledge it is impracticable to do more than concentrate upon an unequivocally significant feature as a basis for classification in a world-wide survey, and to refine areally by supplementary characteristics. The trait that obtrudes itself on our notice is the treatment of collateral as compared with lineal kin in the first ascending and descending generations. It is implicitly the phenomenon that impressed Morgan; it has a bearing on Tylor's and Rivers' theories (*see* below); and constitutes one of Kroeber's categories. Practically, the data usually suffice to characterize systems from this point of view.

The logical possibilities are as follows: (a) Collateral lines are wholly merged in the lineal within a particular generation (generation system); (b) each generation is bisected so that only half the collateral kin are merged in the lineal (bifurcate merging system); (c) the immediate collateral lines are distinguished from the lineal *and from each other* (bifurcate collateral system); (d) collateral lines are distinguished from the lineal, but *not from each other* (lineal).

In standard samples of these four systems logical coherence prevails: *if* the father's brother is called father, he addresses his brother's son as son; *if* there is a separate word for mother's brother, there is likely to be one for nephew. However, discrepancies occur, and a system must sometimes be classed by the preponderance of its affiliations. Taking the classification of uncles for illustration, the scheme may be illustrated by the table on page 85.

The second system, which Morgan and Rivers genetically connect with the first (though in a reverse sense), is not one whit farther from the third; and the bifurcate collateral system sets off the immediate family as sharply from the rest of the universe as

System	Relatives			Criterion
Generation . .	Father	Father's Br.	Mother's Br.	One "father" term
Bifurcate Merging .	"	" "	" "	Two terms; partial merging
Bifurcate Collateral	"	" "	" "	Three terms; no merging
Lineal . . .	"	" "	. .	Two terms; merging only of collaterals

our English lineal system. All four systems actually occur in primitive communities, notwithstanding the widespread notion that they have only the first two, corresponding to Morgan's classificatory types.

With this provisional scheme it is possible to characterize the main areas of the globe. Since regional summaries are available for Australia and North America, it will be best to begin with these continents.

AUSTRALIA

Australian kinship terminologies follow the bifurcate merging plan.

Certain other traits are characteristic. Among these is the use of separate terms for maternal and paternal grandparents. Thus, the Kakadu in Northern Australia call the father's father *kaga*, but the mother's father *peipi*. With many tribes this trait is coupled with the reciprocity principle: in Arunta, *arunga* designates simultaneously the father's father and the son's child. Again, the world-wide distinction between the speaker's elder and younger siblings often displays refinement, so that in Arunta the father's elder brother's sons are "elder brothers," while the father's younger brother's sons are "younger brothers." More rarely, as among the Mungarai, the uncles and aunts themselves are distinguished with reference to their age as compared with the speaker's parents.

While these features have parallels in remote areas, others seem distinctive. According to Radcliffe-Brown, all nomenclatures of the region conform to two types, correlated with distinct forms of marriage law. In type I., as found among the West Australian Kariera and the Urabunna of the Lake Eyre region, the father's father is classed with the mother's mother's brother; by the correlated matrimonial rule a man is prohibited from marrying any woman unless she stands to him in the relation of a mother's brother's daughter. In type II., the mother's mother's brother is distinguished from the father's father, being often classed with the mother's mother; here the prescribed marriage is between the children of two female cross-cousins, a man marrying his mother's mother's brother's daughter's daughter. This second type is of wider distribution than the first, having been discovered among the Dieri, the Central tribes generally, from the Arunta northward to the Anula and Mara, and among such West Australians as the Mardudhunera.[1]

Probably most of the tribes substitute relationship terms for personal names in ordinary intercourse, but the central Australians only tabu sacred appellations, while secular names are used in address, interchangeably with the kinship terms.[2]

A feature worth noting is the absence of terms of affinity. This is evidently to be correlated with the fact that in Australia marriage is prescribed with definite blood relatives. Accordingly there is no necessity for coining new words for connections by marriage. This same trait may be expected to occur in greater or lesser degree in other parts of the world where corresponding forms of marriage with blood relatives are either obligatory or at least preferred.

NORTH AMERICA

North America north of Mexico may be split into two main divisions. Among the Eskimo, in southern British Columbia, the Basin states, Washington, Oregon, and part of California, there are predominantly lineal or bifurcate collateral systems; in the remainder of the continent the terminologies are bifurcate merging. These two main areas correspond roughly to a social organization on the family basis and a clan organization, respectively.

Two Australian features, the reciprocity principle and the discrimination of maternal and paternal grandparents, occur exclusively, or nearly so, in the Far West. However, they do not appear with bifurcate merging traits.

Primarily on the basis of cousin grouping Spier has established eight varieties of nomenclature.[3] The Iroquois type maintains the separation of generations, treats parallel cousins as siblings, and designates cross-cousins by a specific cousin term. The Mackenzie Basin type drops distinctions between cousins, treating all alike as siblings. The Eskimo type resembles the foregoing in merging parallel and cross-cousins, but separates them from siblings. The Omaha systems, embracing several Californian as well as Central tribes, distinguish among cross-cousins. The father's sister's children are regarded as sister's children, which classes them (on bifurcate merging principles) as children if the speaker is a woman. Correlatively, the mother's brother's daughter is classed as a mother, while the mother's brother's son is equated with the mother's brother. In the Crow type the reverse confusion of generations occurs; the father's sister's son is a "father" and addresses his mother's brother's children as his "children"; the father's sister's daughter is a father's sister.

Spier's remaining varieties rest on other principles. His Salish type diverges in displaying lineal features. The Acoma type is segregated by virtue of its three grandparental terms,—one for a man's grandfather, another for a woman's grandmother, a third for a grandparent of the opposite sex. Finally, the Yuman variety is characterized by a refinement of age distinctions,—the father's elder brothers and mother's elder sisters being distinguished from their younger siblings, while parallel cousins are sometimes classed as elder or younger siblings according to their parents' rather than their own ages.

Spier's types avowedly embrace tribes neither geographically nor linguistically close to their eponyms. Thus, the Iroquois type embraces the Iroquois, Ojibwa, Cree, Dakota, some Californian groups, and the Tsimshian of British Columbia.

Based on different principles, Spier's findings (for which he deprecates any interpretation) are not at once wholly convertible into our terminology. However, the Salish case, which he refuses to class by the cousin criterion as of the Mackenzie Basin category, is coextensive with the lineal type. Moreover, both his Omaha and Crow types are varieties of the bifurcate merging type. This, in its classical Seneca form, largely coincides with Spier's Iroquois type, though his stressing of cousin terminology leads to the admission of several tribes who do not merge parents' siblings and parents. In Spier's scheme, the Eskimo are segregated because they use a distinctive cousin term for all cousins. Their separation is undoubtedly warranted. Morgan himself, though describing their system as "classificatory," shows that the nomenclature has "but two, out of ten, of the indicative features of the system of the Ganowanian family" and that "in the greater and most important fundamental characteristics of this system it is wanting."[4] On Morgan's evidence, the use of individualizing terms for the parents and the segregation of maternal from paternal uncles and aunts, would place the Eskimo under the bifurcate collateral head; more recent data for another local division are confirmatory.[5]

Spier's Acoma and Yuman varieties, logically outside his own scheme, hardly merit separate categories, as he himself admits in the Acoma case.

A summary classification of the North American systems thus leads to the following tentative scheme:

[3]L. Spier, *The Distribution of Kinship Systems in North America*, Univ. of Washington Pub. in Anthropology, Seattle, 1925, vol. 1, 69–88.

[4]Morgan, *op. cit.*, p. 277.

[5]D. Jenness, *The Life of the Copper Eskimos*, Ottawa, 1922.

1. Bifurcate Merging	(a)	Iroquois; Dakota; Ojibwa
	(b)	Omaha; Menomini, Sauk; Miwok, Wintun
	(c)	Crow; Pawnee; Creek; Cherokee; Hopi; S. Pomo; Tlingit
2. Bifurcate Collateral		Eskimo, Mono
3. Lineal		Salish; Nootka, Kwakiutl

The Generation system is lacking. Faintly adumbrated, it appears in Spier's Mackenzie Basin type, but the generation principle is restricted in application, so that there is no approach to the Hawaiian scheme. Various Californian and Basin tribes classed by Spier as of the Mackenzie pattern appropriately fall under the bifurcate collateral group, deviating from the norm only in the grouping of cousins. Such tribes as the Northwestern Maidu belong to the same category and show how this may approach the merging type: parallel cousins here coincide with siblings, while cross-cousins are separated by a special term.[1] The gap between this Maidu and the Iroquois system is thus reduced to the distinction the former maintains between the father and his brother, the mother and her sister.

Sporadically, instances occur in otherwise bifurcate merging systems of a partial failure to bifurcate. Thus, the Crow, though only in direct address, use one term for the mother and either kind of aunt.

Personal names are generally eschewed in address.

CENTRAL AND SOUTH AMERICA

Central American systems are known mainly through such sources as Gilberti's *Diccionario de la lengua Tarasca* (1559), Molina's *Vocabulario de la lengua Mexicana* (1571), and Beltran's *Arte del idioma Maya* (1742).[2] The distinction of elder and younger sibling is general, and so is the use of reciprocal terms between different generations. Thus, Maya *mam* is applied to the maternal grandfather and the daughter's son. The principle of reciprocity occurs among the Miskito of Nicaragua, *dapna* designating father-in-law and son-in-law, as well as mother-in-law and daughter-in-law in female speech. The former classification is shared by the Chibcha of Colombia. In the Ucayali region, the Sipibo apply the word *rayos* to parent-in-law and son-in-law, while the words for maternal uncle and sister's son—*cuca* and *cucu* suggest a common stem.[3] In America there is thus a fairly continuous distribution of the reciprocity principle extending from British Columbia through the Pacific and Basin States into Mexico and northern South America.

Several tribes in Latin America recognize to an unusual extent Kroeber's category of the speaker's sex. While a Cakchiquel man calls his son *cahol* and his daughter *mial*, a woman uses *val* and *vixocal*.

From the scanty material accessible it is not clear how commonly bifurcate merging systems occur south of the Rio Grande. Molina's Nahuatl nomenclature is Hawaiian in grouping all uncles with the father, *tlatli;* but it is lineal in segregating aunts, *auitl* from the mother, *nantli*, and all nepotic kin as *machtli* from the son *tepitlzin* and daughter, *teichpuch*. The Cakchiquel use of *tata* for father and paternal uncle is true to the bifurcate merging type, but the reported classification of the *paternal* aunt with the mother, *te*, while both maternal aunt and uncle are called *vican* is so anomalous as to call for corroboratory evidence.[4]

Lineal uncle and aunt terms are reported for the Pomeroon Arawak. On the whole, the frequency of lineal and bifurcate collateral features arrests our attention. Thus, the Miskito, while using for the maternal aunt a word from the stem for mother (*yapti;* mother's sister: *yaptislip*), call the father *aisa*, the paternal uncle *urappia*, the mother's brother *tarti*. A glossary of Arawakan languages shows no discrimination between paternal and maternal uncles except in Siusi; there the bifurcate collateral rather than the bifurcate merging principle obtains since the father's brother is not identified with the father. A single term for aunt (distinct from mother) indicates either inconsistency or inaccurate reporting.[5] The Tupi generic terms exist for aunt and uncle (*aixe* and *tutyra*), but the father term is said to be applicable to all the father's male kin. In short, there is a mingling of lineal and merging features.[6] More consistently, the Sipibo separate the father, *papa*, from both the father's brother, *eppa*, and the maternal uncle, *cuca*, and similarly segregate the mother from the maternal as well as the paternal aunt (*tita, huasta, yaya*, respectively; it is not clear to what extent the matter is complicated by the use of separate words by men and women). The Araucanian terminology is in part bifurcate collateral: the father, *chao*, is distinguished from his brother, *malle* and his brother-in-law, *huecu;* while the mother's sister is designated by a derivative from the mother term.[7]

It cannot be denied that there are nomenclatures of the usual "classificatory" type. According to Ruiz de Montoya (1640), the Guarani was of this order.[8] Nevertheless, the South American tendency toward collateral or lineal usage cannot be ignored.

ASIA

In Asia the wide distribution of status terms expressive of relative seniority is noteworthy, differences of generation being sometimes disregarded, while again the relative seniority of relatives other than those immediately concerned may be significant. The system of the Turkic Yakut of northern Siberia illustrates some of the relevant complications. Radically of the bifurcate merging type, it groups together as *agas* the elder sister and all older women in the speaker's clan, those younger being designated as *babys*, and the words for elder brother are similarly extended. But the seniority idea overrides the generation principle when *ini* designates not only younger brother or cousin within the clan, but also, the father's younger brother and his son; or when *ogom* is applied indifferently to a child, a grandchild, and even to younger people without reference to relationship. Again, while the father's elder brother is called by a derivative from the father term, this same word is extended by the seniority principle to the mother's father; and while *tay* marks off the maternal from the paternal uncles, the mother's sisters are called according to their age with reference to the mother, *tay agas* and *tay babys*. Thus, since the mother is *yä*, there is in so far forth bifurcation without merging.[9]

When the two parental lines are discriminated and the parents' siblings are set off from the parents by mere modifiers of the primary "parent" stem, it seems legitimate to speak of a basically bifurcate merging system. The primitive Sinitic languages in part present this phenomenon and suggest that the proto-Chinese system may have conformed to this model. Its present form is puzzling. Morgan vacillated between calling it Malayan or Turanian, *i.e.*, a generation or a bifurcate merging system. If we stress the specialization of, say, uncles by modifiers rather than the use of a common primary stem, it would be recognized as collateral; otherwise it might rank as a generation system. Some traits however, such as the classing of brother's sons by males indicate bifurcation. It is evident that emphasis on status and seniority would cause a drift from the bifurcate merging toward the generation pattern. Of the primitive members of the Sinitic stock, the Sema, Ao, Angami and Lhota fall rather clearly under the bifurcate merging division, some of them definitely presenting the Omaha variety. Thus, Lhota *omo, Sema angu*, Chongli Ao *okhu* mean the maternal uncle *and* his son; Sema *atikeshiu*, Lhota *orrho*, and Chongli *anok* refer to the sister's son and the father's sister's son in male speech.

The complete lack of certain kinship terms in some Assamese tribes is remarkable; in Angami, for example, parallel cousins can be designated only by their personal names. The Chinese *may* combine such names with the specific kinship terms.[1]

Typical nomenclatures of the bifurcate merging type occur among the peoples of Southern India (including the Toda) and the Vedda of Ceylon. Here, and in other tribes of the area showing this pattern in obscured form, the terminology is affected by cross-cousin marriage. Since a Kachin seeks to marry the daughter of his maternal uncle, he calls his father-in-law and his mother's brother alike *tsa;* while in Mikir the sister's son and the son-in-law are both a man's *osa,* and the wife's brother is his *òng-so* or "little maternal uncle," in other words, his maternal uncle's son.[2]

The two Negrito tribes of Southern Asia differ radically inasmuch as in address the Semang of the Malay Peninsula avoid personal names, while the Andamanese use them exclusively. They resemble each other in stressing status in their nomenclature. Indeed, it seems doubtful whether the Andamanese have any true kinship terms. Though a parent may be individualized by prefixing the personal pronoun to an appropriate noun, this by itself expresses no bond of consanguinity but simply the status of being *some one's* parent. Correspondingly, other words denote relative seniority in varying degrees: *mama* extends to all considerably older persons such as grandparents and parents-in-law. The Andamanese nomenclature lacks bifurcation completely and might be treated as a variety of the generation system; this feature, linked with the vocative use of names, suggests affiliation with Polynesia, where however, generation terms are limited to actual kin. The Semang system is not so well known, but bifurcation seems undeveloped. From *ai,* father, designations for *either* parent's elder and younger brother are formed by the addition of age-suffixes; the word for mother with the appropriate suffix means *either* parent's elder sister, while a new stem designates a younger sister of father or mother. We shall not go far wrong in assigning this system also to the generation category.[3]

In western Asia, the Semitic tribes have been treated as typical of the "descriptive" pattern. As has been shown, the descriptive *technique* is wholly consistent with a "classificatory" meaning. The Arabic terminology is on the face of it bifurcate collateral. It is partly shaped by the custom of parallel-cousin marriage, so that father's brother and father-in-law are identified in fact and in masculine speech. The absence of a common word for paternal uncle in Semitic languages has suggested the hypothesis, as yet awaiting confirmation, that the proto-Semitic system was of the merging type.[4]

Lineal systems occur in northeastern Siberia among the Koryak and Chukchee, where clans are lacking. Both tribes distinguish younger and elder siblings, and the Chukchee have even a separate term for "middle" brother. The Yukaghir terminology presents disparate features. In a sense, the parents are individualized, the children are set off from nepotic kin, and the distinction between paternal and maternal uncles indicates a bifurcate collateral system. However, some of the uncle-aunt words are etymological derivatives from the parent terms, suggesting a merging principle. In addition, the seniority principle of the Yakut order plays a large part, putting both grandmothers in the same class with the father's elder sister, both grandfathers with the elder brother. The technique is sometimes denotative, sometimes descriptive. It is plausible to regard this medley as at least partly the result of distinct culture layers. An archaic system resting on the family may have been complicated by a bifurcate merging system, stressing the seniority idea. In other words, a palae-Asiatic layer may have had Yakut-like accretions.[5]

AFRICA

In the southern half of the continent bifurcate merging systems prevail. The Hottentot nomenclature approximates the Iroquois pattern, though the occasional classification of the mother's brother's son with the maternal uncle marks a deviation in the Omaha direction. For the Bushmen, data are inadequate, though reported suggestions of a "classificatory system" indicate another sample of the Iroquois form. With modifications of a minor character this holds for most of the Bantu. There is little to support Morgan's interpretation that the terminology is "Malayan." His guess that the stem for mother's brother was a recently evolved substitute for the father term is refuted by its occurrence in much the same form among the Thonga and Wayao, while the concept is attested for as far north as Uganda and the Congo. The very fact cited by Morgan that a single word denotes the paternal aunt and the father proves the stress on bifurcation, even to the detriment of sex distinctions. The generation factor doubtless asserts itself in the classification of all cousins with siblings, but this is far from universal in Bantu speech. The Wayao, *e.g.,* distinguish cross-cousins from parallel cousins by a distinctive designation. Moreover, the very essence of the generation principle is ignored by a number of tribes. The Thonga, like the Hottentot, *may* call the mother's brother's son *malume,* like the maternal uncle, while the daughter of the mother's brother is a "mother," and sometimes the grandchild and the sister's child fail to be distinguished.

Again, the wife's parent and the wife's elder sibling fall into the same Thonga category, and sometimes the grandfather term embraces the maternal uncle. Finally, the Wayao have a reciprocal term for parent-in-law and child-in-law. There is thus no warrant for putting the Bantu with the Polynesians: their system is basically of the bifurcate merging type, modified locally by various causes, sometimes along Omaha lines.[6]

The Hamitic and Hamitoid tribes are generally credited with "descriptive" systems. In fact, the descriptive technique may be employed to an unusual degree, so that the 'Afar of the East Horn call a brother "mother's son." This, however, does not preclude a classificatory meaning for the descriptive designation, much less for other parts of the same nomenclature. Galla *abba,* for example, may be applied not only to the father but as an honorific appellation to any old man. The Somali system is definitely bifurcate collateral. Among the Masai the paucity of genuine kinship terms is no less remarkable than certain correlated usages. While father's and mother's siblings are distinguished from the parents by descriptive phrases, this discrimination extends only to reference, while in address the father's brother is a father. Most kinsmen, however, are not called by terms of consanguinity or affinity but according to the livestock they have received from the speaker: if he has presented a man with a bull (*ainoni*), the beneficiary is called *b-ainoni,* etc. Generations often fail to be separated: *koko* embraces aunt *and* grandmother, and with a suffix the word is applied to a woman's grandson. Similarly, a reciprocal stem embraces grandfather and a man's grandson.[7]

Among the Sudanese negroes a great diversity obtains. The Timne terminology is lineal, the words for aunt and uncle being generic and distinct from the parent terms, while cousins in a lump

are separated from siblings. Some of the languages display an amazing paucity of primary stems, lacking even distinct vocables for siblings. Thus, in Ewe "brother" is designated by the descriptive compound "mother's-child-male," and the Edo construct descriptive compounds for "brother" according to whether he is fellow-child through the father or the mother. However, the bifurcate merging principle is by no means eliminated since even in Edo the paternal uncle is frequently classed with the father in address. Nor are typical systems on the bifurcate merging plan lacking. The Susu nomenclature conforms to the Iroquois standard, and this essentially holds for the Ashanti also. Here, however, cross-cousin marriage in some measure has affected classification and the rather extensive use of reciprocal terms partly breaks down the barriers between generations. Thus, *ase* means spouse's parent *or* child's spouse; *nana* is applied to the grandparent and his sibling *or* to the grandchild and the sibling's grandchild. Some relatives *may* be designated descriptively, but this does not interfere with the "classificatory" use of the phrase. For example, the father's brother's child is called either "brother" or "father's child" without any individualization of meaning in either case.[1]

Finally, the Lango terminology is of the bifurcate merging type, the partial use of the descriptive technique being once more consistent with "classificatory" meanings. A noteworthy feature is the anomolous designation of cousins. The maternal uncle's son and daughter are designated by descriptive compounds; a distinct stem, with varying vocalic sex-prefix (*okeo, akeo*), is applied to the paternal aunt's children; another stem, similarly varied, denotes the mother's sister's son and daughter; while the father's brother's children are treated as siblings. Thus, neither the two kinds of cross-cousins nor the two kinds of parallel cousins are grouped together. The classification of the father's sister's children with the sister's children exhibits an element of the Omaha variety, while other deviations from the generation principle can be derived from rules of widow-inheritance. The occasional designation of a father's sister's son as father is contingent on inheritance of a maternal uncle's widow, making her children the heir's step-children. The Lango nomenclature has been partly shaped by loans from Hamitic neighbours, which have been engrafted on the old Nilotic nomenclature.[2]

INDONESIA AND OCEANIA

Morgan based his "Malayan" type on Polynesian terminologies. For the Malay branch of the Malayo-Polynesian family he had a single incomplete report from Borneo, which seemed, however, to conform to the Hawaiian norm. There is still great dearth of material for this area. In the Philippines, bifurcation is generally lacking and approximation to the generation system frequently results. But even there the Tinguian, Professor Fay-Cooper Cole states, distinguish uncles and aunts from parents, *i.e.*, fall into the lineal category. This is at least partly true of some "Pagan" systems from Borneo, where aunt and mother are indeed merged, but where the father is distinguished from uncles generally. The importance some Malayans attach to status is probably significant; where a parent is addressed teknonymously and a grandfather receives an appropriate title, people are on the high-road to stratifying society in terms of generation. However, the Mentawei islanders, representative of archaic Malayan culture, radically differ from the Polynesians in not using personal names in address. They exhibit conflicting tendencies toward a generation, a bifurcate merging, and a bifurcate collateral system: while "ina" is the term of address for mother and father's sister alike, the latter has a separate term in non-vocative use; the maternal uncle is distinguished from the paternal, and the latter is distinguished from the father except vocatively.[3]

For most of Oceania Rivers has given a convenient summary. Broadly, the Melanesians refrain from using personal names whenever there is a suitable term of relationship, while the Polynesians use personal names even for the closest relatives.

Of the Papuans, the Bánaro, settled on a tributary of the Augusta River, have been accurately described. The differentiation of the maternal uncle suggests a bifurcate merging system, but in other respects they have developed on generation lines, though anomalous matrimonial customs colour the terminology. An interesting distinction is drawn between a paternal aunt who has and one who has not been exchanged for the speaker's mother: the former is called "mother," the latter "maternal uncle's wife." In the contemporary generation, siblings are distinguished according to seniority, cousins are treated as siblings, but are designated in accordance with the relative seniority of the connecting *parents*. This feature is shared by such Melanesians of New Guinea as the Jabim. These tribes fall into the bifurcate merging category. Reciprocal terms occur for grandfather and grandson, maternal uncle and sister's son, parent-in-law and child-in-law.[4]

HISTORICAL AND SOCIOLOGICAL INTERPRETATIONS

Morgan inaugurated both historical and sociological interpretations of the facts he scheduled. Starting from the axioms that kinship classifications were "independent of the mutations of language" (p. 506) and that they could not be diffused except if the phonetic symbols themselves were borrowed, he accepted the similarity of systems as proof of *racial* identity. He thus inferred the unity of the Dravidians and the American Indians, and that of the Zulu and the Hawaiians (p. 466). Apart from the questionableness of the premises this argument would lead to the absurd conclusion that the Eastern North American Indians stood racially much closer to the Melanesians and various Africans than to their congeners of the Basin area. However, by his collation of specific resemblances, Morgan paved the way for sound historical conclusions. For example, he recognized the likeness of certain Central Algonkian and southern Siouan systems (p. 179)—a fact now interpreted as the result of diffusion. Diffusion evidently is the only possible explanation of the concentration west of the Rockies of such features as the discrimination between paternal and maternal grandparents.

Sociologically, Morgan viewed his nomenclatures as indices of family life. The "Malayan" as the simplest was considered the earliest; and since it failed to distinguish the mother's brother from the father, Morgan concluded that the two were identical, *i.e.*, that a man had access to his own sister when the system originated. The introduction of a term for maternal uncle was said to result from the prohibition of such unions when the Turanian-Ganowanian system arose. Finally, the "descriptive" terminology, failing to merge *any* collateral relatives with the direct line of descent, was correlated with the rise of property rights and the parents' insistence on transmitting them only to direct descendants (p. 492f.). The scheme thus forms part of an evolutionary theory explaining the gradual rise of our civilized family out of more or less promiscuous beginnings.

These interpretations are now recognized as basically wrong. Morgan was not warranted in assuming that the Polynesian term translated "father" implied procreation: the facts simply reveal a common status term for all kindred of one generation. Simplicity here, as in many other linguistic phenomena, is a late development, not a badge of antiquity. Three independent investigators, Sternberg in Siberia, Rivers in Oceania, Lowie in North America, have been able to show recent transformations of bifurcate merging nomenclatures in the direction of generation systems.

Morgan's extravagance led Kroeber to reject sociological interpretations almost *in toto*. In reply to criticism by Rivers, he has long since receded from this position, specifically admitting the correlation of certain terminological features with cross-cousin terminology. The issue was thus reduced to a difference in philosophical attitude toward cultural phenomena. Rivers championed a rigid determinism, contending that "not only has the

general character of systems of relationship been strictly determined by social conditions, but every detail of these systems has also been so determined." On the other hand, Kroeber insisted that "the infinitely variable play of the variable factors forbids any true determinations of causality of a sweeping character."[1]

Kroeber was unquestionably right in rejecting Rivers' extreme claim, and in maintaining that since kinship terms were linguistic phenomena, they were subject to alterations of a linguistic character, *e.g.*, extensions in meaning, independently of social conditions. However, he did not sufficiently consider that language represents reality and that in so far as it related to social phenomena it is likely to mirror them, even though imperfectly. The empirical facts of distribution indicate that the correlation between social custom and nomenclature is indeed far from perfect, but fairly high.

First of all, there is an undeniable tendency to designate by separate terms relatives with distinctive social functions. It is not sheer accident that Polynesians generally lack a term for the maternal uncle, but that a term appears with the avunculate. Furthermore, the same term applied to different individuals is an index of their sharing the same duties and claims, as Radcliffe-Brown has pointed out for Australia.

Secondly, how are we to interpret the data of geographical distribution? Rivers found that neighboring Oceanians often differed more widely in their kinship systems than remote tribes. A survey of the world establishes this fact on a broader basis. Morgan's solution of resemblances in Dravidian and Iroquois nomenclature is impossible, but he put his finger on a real problem. When the Omaha of Nebraska resemble the Californian Miwok far more than their fellow-Siouans; when specific Omaha features crop up in some Assamese tribes and again on the upper Nile, the fact naturally arouses curiosity and calls for explanation. If the same social factors uniformly accompany the terminological resemblance, a genuine correlation is established. Thus, the grouping of the mother's brother's son with the maternal uncle in the tribes cited is linked with paternal descent, while the classification of the father's sister's son with the father, and of the father's sister's daughter with the paternal aunt generally accompanies maternal descent. We are not dealing with a simple causal nexus, for there are matrilineal tribes like the Seneca and patrilineal tribes like the Ojibwa who do not override the generation principle in this fashion. But a functional relationship remains. It is conceivable that the Omaha and Crow varieties of the bifurcate merging type depend on additional factors that may some time be discovered.

That, without prejudice to other functional relations, a high correlation obtains between a clan organization and the bifurcate merging system, seems certain. Clanless tribes like the Andamanese, Chukchee, Basin Shoshoneans, Hawaiians, have no terminologies of this type; characteristic clan organizations are almost uniformly coupled with them. Tylor's generalization, corroborated by Rivers and Lowie for Oceania and North America, respectively, seems to hold.[2] Yet it is possible to derive the terminology from the joint effect of the levirate and the sororate, institutions probably quite as widely distributed as the clan organization. True, they do not explain why in the common Iroquois variety of the type parallel cousins of the same sex are grouped together, while cross-cousins of the same sex are segregated under a common term of their own. Tylor's idea that the moiety represents the primeval clan does explain this; but large sections of the world with the bifurcate merging nomenclature—notably Africa—lack moieties.

In the present state of our knowledge, then, we may say that while social correlations of terminological features are undeniable, we are not usually in a position to determine a simple cause-effect relationship. There are often alternative explanations: the mother's brother may be identified with the father's sister's husband because of cross-cousin marriage *or* because they both belong to the same exogamous moiety or because two households arrange to marry off their respective daughters to the boys in the other household (Rivers). The safe rule is to reject any social determinant of a nomenclatorial trait unless it is reported as extant in the tribe or at least in the general area in question.

Other phases of the problem must be considered. An institution may be overshadowed by coexisting institutions or it may not yet have had time to assert itself terminologically. The Miwok, *e.g.*, practise cross-cousin marriage but their terminology shows a far deeper impress of rival forms of marriage. It seems a fair conclusion that the latter are of greater antiquity.[3]

Diffusion presents a further complication. While harmony between the nomenclature and the social structure is frequent, there are discrepancies that can be most readily interpreted by borrowing. To exemplify, there are tribes with a bifurcate merging terminology that lack clans, but their location suggests that they have borrowed a neighbor's nomenclature. It would be dangerous to infer that they had at one time been organized into clans, unless extraneous data so suggest.

Finally, there are the linguistic factors stressed by Kroeber. When nearly all Siouan languages have a separate term for paternal aunt, the lack of such a word (in address only) among the Crow must be interpreted as a late development; and the use of the "mother" word appears as a characteristic sample of linguistic extension,—the same phenomenon as when English uses "wife" as a special term of affinity while the cognate German *Weib* applies to woman generically. The reality of such phenomena militates against any attempt to reduce the whole of kinship terminology to social causes. There will always be residual phenomena resisting interpretation on any but linguistic lines. This means that they are in a sense unique facts that can be understood after they have been observed but that could not be deduced from general principles.[4]

These cautions limit but do not destroy the sociological significance of relationship terminologies. When all allowances are made for disturbing factors, a host of correlations remain between kinship features and sociological factors. When more intensive studies of large linguistic families shall be available, it will be possible to balance with greater nicety the relative importance of sociological and other factors as determinants. (R. H. Lo.)

RELATIVITY. The progress of natural science in the first quarter of the present century was especially noteworthy through the appearance of the doctrine of relativity, and its almost immediate acceptance by the scientific world in general. The need for some such theory had long been felt and was becoming continually more urgent. As far back as 1887 Michelson and Morley, experimenting for quite another purpose, had obtained results which obstinately refused to fit into 19th-century conceptions of the general nature of the universe. Experiments in other directions soon indicated that the difficulties thus revealed were not isolated difficulties confined to one special corner of science, but extended throughout a large part of electrical and optical science. Theoretical discussions by Lorentz, Larmor and others drew attention to the serious nature and extent of the difficulties which had arisen, and pointed, although somewhat vaguely, to the direction in which a solution was likely to be found.

In 1905 a paper appeared by Albert Einstein, then professor of theoretical physics in the University of Berne, which showed, although its implications were not at first fully understood, that the difficulties revealed by the experiment of Michelson and Morley, as well as others which had subsequently come to light, could be removed at the expense of pouring into the melting-pot all the ideas then prevalent as to the fundamental nature and meaning of space and time. In effect, although this again was not

realized at the time, it went further and showed that the experiments in question actually compelled a recasting of these ideas.

At this time gravitation held obstinately aloof from all other physical phenomena; an ether had been devised which explained optical and electrical phenomena with fair success, but it refused to find room for the phenomenon of gravitation. In 1915 Einstein published further papers which showed that gravitation admitted of a very simple explanation in terms of the new ideas as to the nature of space and time. The gravitation which was explained in this way was, however, just a shade different from the gravitation of Newton. When it was realized that the gravitation of nature was also just a shade different from that of Newton, and it was further discovered that nature ranged herself completely with Einstein in this matter, then the acceptance of Einstein's theory was universal and complete.

While gravitation fitted quite naturally into the new scheme of nature demanded by the theory of relativity, it was found to be less easy to fit in the general phenomena of electro-magnetism. The last few years have seen a great deal of discussion as to the way in which these must be joined on to Einstein's general theory of relativity and, as we shall see below, the issue is still in doubt.

General Nature of the Principle.—Science advances in two ways, by the discovery of new facts, and by the discovery of mechanisms or systems which account for the facts already known. The outstanding landmarks in the progress of science have all been of the second kind. Such, for instance, was the Copernican system of astronomy, which explained the already known motions of the planets; such was the Newtonian mechanism (the force of gravitation) which explained the elliptic orbits of the planets and the earth's pull on terrestrial bodies; such was the Darwinian mechanism of natural selection, which explained the survival of some species and the extinction of others. Such also is the theory of relativity.

The scientist's desire to discover mechanisms or systems arises no doubt primarily from the constitution of the human mind; our intellects, unsatisfied with a mere accumulation of facts, impel us ever to search for the causes underlying the facts: *Vere scire est per causas scire*. But to the working scientist the discovery of a mechanism has an additional and more practical value. When he has found a mechanism which will account for certain laws, he can proceed to examine the complete set of laws which the mechanism demands. If his mechanism corresponds with sufficient closeness to reality he may in this way be led to the discovery of new natural laws. On the other hand, the new laws deduced from the supposed mechanism may be false. If the falsity of the new laws is not at once revealed science may for a time be led into wrong paths. When more accurate experimenting or observation discloses that the new laws are not true a recasting of ideas becomes necessary, and the branch of science concerned may experience a time of revolution followed by a period of rapid growth.

An obvious illustration of these general statements is provided by the history of astronomy. The laws of the motions of the planets, as observed from the earth, were tolerably well known to the Greeks. They had also evolved an explanatory mechanism starting from the premise, which seemed to them to be necessary on metaphysical grounds, that the paths of the planets must necessarily be circles. The earth was the centre of the universe and round this revolved spheres to which the planets were attached. The retrograde motion of the outer planets was explained by supposing that they were attached to secondary spheres revolving about points on the primary spheres which in turn revolved about the earth. This mechanism of cycles and epicycles as an explanation of planetary motion held the field for 18 centuries. Finally the observations of Tycho Brahe provided a test which revealed the falsity of the whole structure. The position of Mars was found to differ from that required by the mechanism of epicycles by an amount as great as eight minutes of arc. "Out of these eight minutes," said Kepler, "we will construct a new theory that will explain the motions of all the planets."

The history of the succeeding century of astronomy need not be recapitulated here. The earth yielded its place as the centre of the universe, and the structure of cycles and epicycles crumbled away. The laws of planetary motion were determined with a precision which for the time appeared to be final. The mechanism underlying these laws was supposed to be a "force" of gravitation. This force was supposed to act between every pair of particles in the universe, its intensity varying directly as the product of the masses of the particles and inversely as the square of the distance separating them—the famous law of Newton.

In science, history repeats itself and, in recent years, the theory of relativity has provided a further instance of the general processes we have been considering. Under the Newtonian mechanism every planet would describe a perfect ellipse about the sun as focus, and these elliptic orbits would repeat themselves indefinitely except in so far as they were disturbed by the gravitational forces arising from the other planets. But, after allowing for these disturbing influences, Leverrier found that the orbit of the planet Mercury was rotating in its own plane at the rate of 43 seconds a century. Various attempts have been made to reconcile this observed motion with the Newtonian mechanism. The gravitational forces arising from the known planets were demonstrably unable to produce the motion in question, but it was possible that Mercury's orbit was being disturbed by matter so far unknown to us.

Investigations were made as to the disturbance to be expected from various hypothetical gravitating masses—a planet or a ring of planets between Mercury and the sun, a ring of planets outside the orbit of Mercury, a belt of matter extended in a flattened disc in a plane through the sun's centre, an oblateness greater than that suggested by the shape of the sun's surface, in the arrangement of the internal layers of the sun's mass. In every case the mass required to produce the observed disturbance in the motion of Mercury would have also produced disturbances not observed in the motions of the other planets. The solution of the problem came only with the theory of relativity. Just as Tycho's eight minutes of arc, in the hands of Kepler and Newton, revolutionized mediaeval conceptions of the mechanism of the universe, so Leverrier's 43 seconds of arc, in the hands of Einstein, has revolutionized our 19th-century conceptions, not only of purely astronomical mechanism, but also of the nature of time and space and of the fundamental ideas of science. The history of this revolution is in effect the history of the theory of relativity. It falls naturally into three chapters, a first narrating the building of the earlier physical theory of relativity, a second dealing with the extension of that theory to gravitation, and a third, which is still in process of being written, attempting to include electro-magnetism in the physical system presented by the existing theory of relativity.

THE PHYSICAL THEORY OF RELATIVITY

The earliest successful attempt to formulate the laws governing the general motion of matter is found in Newton's laws. The first law states that:—

Every body perseveres in its state of rest or of uniform motion in a right line unless it is compelled to change that state by forces impressed thereon.

In this law no distinction is made between rest and uniform motion in a straight line, and the same is true of the remaining laws. Hence follows the remarkable property to which Newton draws explicit attention in his fifth corollary to the laws of motion:—

The motions of bodies included in a given space are the same among themselves, whether that space is at rest, or moves uniformly forwards in a right line without any circular motion.

As a concrete application of his principle, Newton instances "the experiment of a ship, where all motions happen after the same manner whether the ship is at rest or is carried uniformly forward in a right line." Just as a passenger on a ship in a still sea could not determine, from the behaviour of bodies inside the ship, whether the ship was at rest or moving uniformly forward, so we cannot determine from the behaviour of bodies on our earth whether the earth is at rest or not. We believe the earth to be moving round the sun with a speed of about 30km.

a second, so that there can be no question of the earth being permanently at rest, but we are unable to determine whether it is at rest at any specified point of its orbit, or, in the probable event of its not being at rest, what its absolute velocity may be. There is no more reason for thinking the sun, than the earth, to be at rest. Newton wrote as follows:—

"It is possible that in the remote regions of the fixed stars, or perhaps far beyond them, there may be some body absolutely at rest, but impossible to know, from the positions of bodies to one another in our regions, whether any of these do keep the same position to that remote body. It follows that absolute rest cannot be determined from the position of bodies in our regions."

The above quotations are all from the first book of the *Principia Mathematica*. Previous to them all Newton writes: "I have no regard in this place to a medium, if any such there is, that freely pervades the interstices between the parts of bodies." The two centuries which elapsed after the publication of the *Principia* witnessed a steady growth of the belief in the reality of such an all-pervading medium. It was called the ether, or aether, and by the end of these two centuries (1887) it was almost universally believed that light and all electro-magnetic phenomena were evidence of actions taking place in this ether. Light from the most distant stars was supposed to be transmitted to us in the form of wave motions in the ether, and we could see the stars only because the sea of ether between us and these stars was unbroken. It had been proved that if this sea of ether existed it must be at rest, for the alternative hypothesis that the ether was dragged about by ponderable bodies in their motions had been shown to be incompatible with the observed phenomenon of astronomical aberration and other facts of nature. On this view it was no longer necessary to go to Newton's "remote regions of the fixed stars, or perhaps far beyond them," to find absolute rest. A standard of absolute rest was provided by the ether which filled our laboratories and pervaded all bodies. Owing to our motion it would appear to be rushing past us, although without encountering any hindrance—"like the wind through a grove of trees," to borrow the simile of Thomas Young. The determination of the absolute velocity of the earth was reduced to the problem of measuring the velocity of an ether current flowing past us and through us.

In this same year (1887) the first experimental determination of this velocity was attempted by the Chicago physicist Michelson. The velocity of light was known to be, in round numbers, 300,000 km. a second, a velocity which was interpreted as representing the rate of progress of wave motion through the ether. If the earth were moving through the ether with a velocity of 1,000km. a second, the velocity of light relative to a terrestrial observer ought to be only 299,000km. a second when the light was sent in exactly the direction of the earth's motion through the ether, but would be 301,000km. a second if the light was sent in the opposite direction. In more general terms, if the earth were moving through the ether, the velocity of light, as measured by a terrestrial observer, would depend on the direction of the light, and the extent of this dependence would give a measure of the earth's velocity. The velocity of light along a single straight course does not permit of direct experimental determination, but the same property of dependence on direction ought to be true, although to a less extent, of the average to-and-fro velocity of a beam of light sent along any path and then reflected back along the same path.

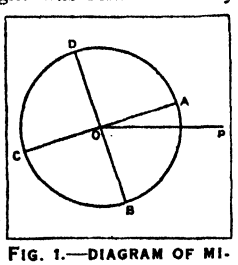

FIG. 1.—DIAGRAM OF MICHELSON'S APPARATUS It measures the earth's velocity through the ether

It was through this property that Michelson attempted to measure the earth's velocity through the ether. The apparatus was simple in principle. A circular table ABCD (*see* fig. 1) was arranged so as to be capable of slow rotation about its centre O. Light sent along CO was divided up at O into two beams which were made to travel along perpendicular radii OA, OB. The arms OA, OB were made as equal as possible and mirrors were placed at A and B to reflect the beams of light back to O. An extremely sensitive optical method made it possible to detect even a very slight difference in the times of the total paths of the two beams from O back to O. There would in any case be a difference owing to the necessarily imperfect equalization of the lengths of the arms OA, OB, but if the earth is moving through the ether in some direction OP, and if the table is made to rotate slowly about O, then this difference ought itself to vary on account of the earth's motion through the ether. Michelson, and afterwards Michelson and Morley in collaboration, attempted to estimate the amount of this variation. No variation whatsoever could be detected, although their final apparatus was so sensitive that the variation produced by a velocity through the ether of even 1km. a second ought to have shown itself quite clearly.

Thus to the question "What is our velocity through the ether?" nature appeared to give the answer "None." It was never suggested that this answer should be accepted as final; this would have brought us back to a geocentric universe. Clearly either the question had been wrongly framed or the answer wrongly interpreted. It was pointed out in 1893 by Fitzgerald, and again independently, in 1895, by Lorentz, that the *null* result of the Michelson-Morley experiment could be explained if it could be supposed that motion through the ether altered the linear dimensions of bodies. They both showed that the experiment would invariably and of necessity give a *null* result if every body moving through the ether with a velocity u was contracted in the direction of its motion in the ratio $\sqrt{1-\frac{u^2}{c^2}}$, c being the velocity of light. The supposition that such a contraction occurred was not only permissible—it was almost demanded by electrical theory. Indeed, Lorentz had already shown that if matter were a purely electrical structure, the constituent parts would of necessity readjust their relative positions when set in motion through the ether and the final position of equilibrium would be one showing precisely the contraction just mentioned.

On this view, there was no prima facie necessity to abandon the attempt to measure the earth's velocity through the ether. The answer to the problem had merely been pushed one stage farther back, and it now became necessary only to measure the shrinkage of matter produced by motion. It was obvious from the first that no direct material measurement could disclose the amount of this shrinkage, since any measuring rod would shrink in exactly the same ratio as the length to be measured; but optical and electrical methods appeared to be available. Experiments to this end were devised and performed by Rayleigh, Brace, Trouton and Noble, Trouton and Rankine and others. In every case a *null* result was obtained. It appeared then that if the earth moved through the ether this motion was concealed by a universal shrinkage of matter, and this shrinkage was in turn concealed by some other agency or agencies.

At this time the word "conspiracy" found its way into the technical language of science. There was supposed to be a conspiracy on the part of the various agencies of nature to prevent man from measuring his velocity of motion in space. If this motion produced a direct effect x on any phenomenon, the other agencies of nature seemed to be in league to produce a countervailing effect $-x$. A long train of experiments had not revealed, as was intended, our velocity through the ether; they had merely created a conviction that it was beyond the power of man to measure this velocity. The conspiracy, if such there was, appeared to have been perfectly organized.

A perfectly organized conspiracy of this kind differs only in name from a law of nature. The inventor who tries to devise a perpetual-motion machine may come to the conclusion that the forces of nature have joined in a conspiracy to prevent his machine from working, but wider knowledge shows that he is in conflict not with a conspiracy, but with a law of nature—the conservation of energy. In 1905 Einstein, crystallizing an idea which must have been vaguely present in many minds, propounded the hypothesis that the apparent conspiracy might be in effect a law of nature. He suggested that there might be a true law to the effect that "it is of necessity impossible to determine absolute motion by any experiment whatever." This hypothetical law may

again be put in the equivalent form: "The phenomena of nature will be the same to two observers who move with any uniform velocity whatever relative to one another." This may be called the hypothesis of relativity.

The hypothesis in itself was not of a sensational character. Indeed, from the quotations which have already been given from Newton's works, it appears probable that Newton himself would have accepted the hypothesis without hesitation: he might even have regarded it as superfluous. The true significance of the hypothesis can only be understood by a reference to the scientific history of the two centuries which had elapsed since Newton. The Newtonian view that absolute rest was to be found only "in the remote regions of the fixed stars, or perhaps far beyond them," had given place to a belief that absolute rest was to be found all around us in an ether which permeated all bodies. What was striking about the hypothesis was its implication—either that we could not measure the velocity relative to ourselves of a medium which surrounded us on all sides, or else that no such medium existed.

The hypothesis demanded detailed and exhaustive examination. It was for the mathematician to test whether it was in opposition to known and established laws of physics, and to this task Einstein, Lorentz and others set themselves. If the hypothesis proved to be in opposition to a single firmly established law, then of course it must be abandoned. It was unlikely that such an event would occur among the well-established laws, for if it did, the phenomena governed by that law would enable direct measurement to be made of the earth's velocity through the ether, a measurement which had so far eluded all attempts of experimenters. It was among the more obscure and less well-established laws, if anywhere, that discrepancies were to be looked for.

It is impossible here to give a complete account of the many tests to which the relativity hypothesis has been subjected. The result of all can be summed up in one concise and quite general statement:—Wherever the hypothesis of relativity has appeared to be in conflict with known or suspected natural laws, further experiment, where possible, has without a single exception shown the laws to be erroneous, and has moreover shown the alternative laws suggested by the hypothesis of relativity to be accurate. It is only in somewhat exceptional cases that the hypothesis of relativity suffices of itself to determine fully the form of a natural law; these cases constitute the most striking triumphs of the theory. As instances may be mentioned the determination of the law connecting the mass of an electron with its velocity; of the law expressing the velocity of light through a transparent medium in motion (Fizeau's water-tube experiment); and of the formulae for the magnetic forces on moving dielectric media (experiments of Eichenwald and H. A. Wilson).[1]

Before leaving this general statement, particular mention must be made of one special case. A natural law which, at an early stage, was seen to be in conflict with the hypothesis of relativity was Newton's famous law of gravitation—namely, that every particle of matter attracts every other particle with a force proportional to the product of the two masses, and to the inverse square of their distance apart. Either, then, Newton's great law had to be abandoned, or else the hypothesis of relativity had to be discarded, in which case it would immediately become possible, in theory at least, to determine the earth's velocity through space by gravitational means. It is the choice between these two alternatives that has led to the most surprising developments of the theory of relativity; and to these we shall return later.

The hypothesis of relativity, as has already been explained in this section, postulates that the phenomena of nature will be the same to two trained observers moving relative to one another with any uniform velocity whatever. The hypothesis has been so amply tested as regards all optical and electro-magnetic phenomena that no doubt is felt, or can rationally be felt, as to its truth with respect to these phenomena. The hypothesis can be examined and developed in two opposite directions. We may, on the one hand, proceed from the general hypothesis to the detailed laws implied in it; this has already been done, with completely satisfactory results as regards confirmation of the hypothesis. Or regarding the hypothesis of relativity as being itself a detailed law, we may attempt to generalize upward to something still wider. It is this possibility which must for the moment claim our attention.

In 1905 Einstein examined in full the consequences of the hypothesis that one simple optical phenomenon—namely, the transmission of a ray of light in free space—was, in accordance with the hypothesis of relativity, independent of the velocity of the observer. If an ether existed, and provided a fixed framework of reference, then light set free at any instant would obviously travel with a velocity which would appear to an observer at rest in this ether to be the same in all directions, and the wave front at any instant would be a sphere having the observer as centre. On the hypothesis of relativity the phenomenon of light transmission must remain unaffected by the motion of the observer, so that the light must appear, to a moving observer also, to travel with a uniform velocity in all directions, and thus to the moving observer also the wave front must appear to be a sphere of which he is the centre. It is, however, quite obvious that the same spherical wave front cannot appear, to each of two observers who have moved some distance apart, to be centred round himself, unless the use either of the common conceptions of science or of the ordinary words of language is greatly changed. In fig. 2 it is not possible, in ordinary language, that both O and P should at the same instant be at the centre of the sphere ABC. The change to which Einstein was forced is one which has an intimate bearing upon our fundamental conceptions of the nature of space and time; this change it will be necessary to explain in some detail.

Suppose that two observatories, say Greenwich and Paris, wish to synchronize their clocks, with a view to, let us say, an exact determination of their longitude difference. Paris will send out a wireless signal at exact midnight as shown by the Paris clock, and Greenwich will note the time shown by the Greenwich clock at the instant of receipt of the signal. Greenwich will not, however, adjust their clock so as to show exact midnight when the signal is received; a correction of about ·001 second must be made to allow for the time occupied by the signal in traversing the distance from Paris to Greenwich. To turn to mathematical symbols, if t_0 is the time at which a signal is sent out from one station, the time of receipt at a second station is taken to be $t_0+\frac{x}{c}$, where x is their distance apart, and c is the velocity of light. This represents the ordinary practice of astronomers, but it is clear that if the earth is travelling through a fixed ether with a velocity u in the direction of the line joining the two observatories, the velocity of transmission of the signal relative to the two observatories will not be c but $c+u$, and the time of receipt at the second station will be $t_0+\frac{x}{c+u}$. Thus it appears that it is impossible to synchronize two clocks unless we know the value of u, and that the ordinary practice of astronomers will not, as they expect, synchronize their clocks, but set them at an interval apart equal to

$$x\left(\frac{1}{c}-\frac{1}{c+u}\right)$$

which may, to an approximation, be put equal to $\frac{ux}{c^2}$.

According to the hypothesis of relativity, it is impossible ever to determine the value of u, and so it is impossible ever truly to synchronize two clocks. Moreover, according to this hypothesis, the phenomena of nature go on just the same whatever the value of u, so that the want of synchrony cannot in any way show itself—in fact, if it did, it would immediately become possible to measure the effect and so arrange for true synchrony.

As the earth moves in its orbit, the value of u changes, so that its value in the spring, for instance, will be different from its value in the autumn. One pair of astronomers may attempt to synchronize a pair of clocks in the spring, but their synchronization will appear faulty to a second pair who repeat the determination in the autumn. There will, so to speak, be one synchrony for the spring

[1] For references to the original papers dealing with these and other tests of the hypothesis of relativity *see* Cunningham, *The Principle of Relativity*, or J. H. Jeans, *Mathematical Theory of Electricity and Magnetism* (4th or 5th ed.).

and another for the autumn, and neither pair of astronomers will be able to claim that their results are more accurate than those of their colleagues. Different conceptions of synchrony will correspond to different velocities of translation.

These elementary considerations bring us to the heart of the problem which we illustrated diagrammatically in fig. 2. The observer at O in the diagram will have one conception of simultaneity, while the second observer who moves from O to P will, on account of his different velocity, have a different conception of simultaneity. The instants at which the wave front of the light signal from O reaches the various points A, B, C in the diagram will be deemed to be simultaneous by the observer who remains at O, but the observer who moves from O to P will quite unconsciously have different ideas as to simultaneity. At instants which he regards as simultaneous the wave front will have some form other than that of the sphere ABC surrounding O. If the hypothesis of relativity is to be true in its application to the transmission of light signals, this wave front must be a sphere having P as its centre. Einstein examined mathematically the conditions that this should be possible. A precise statement of his conclusions can only be given in mathematical language.

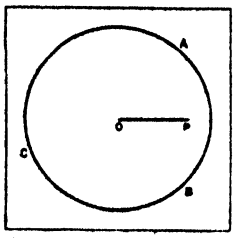

FIG. 2.—DIAGRAM OF MOTION OF OBSERVER AND LIGHT-SIGNAL

The observer who remains at O in fig. 2 may be supposed to make exact observations and to record these observations in mathematical terms. To fix the positions of points in space he will map out a "frame of reference" consisting of three orthogonal axes, and use Cartesian co-ordinates x, y, z, to specify the projections along these axes of the radius from the origin to any given point. He will also use a time co-ordinate t which may be supposed to specify the time which has lapsed since a given instant, as measured by a clock in his possession. Any observations he may make on the transmission of light signals can be recorded in the form of equations between the four co-ordinates x, y, z, t. For instance, the circumstance that light travels from the origin with the same velocity c in all directions will be expressed by the equation (of the wave front):—

$$x^2+y^2+z^2-c^2t^2=0 \quad .. \quad .. \quad .. \quad (1)$$

The second observer who moves from O to P will also construct a frame of reference, and we can simplify the problem by supposing that his axes are parallel to those already selected by the first observer. His co-ordinates, to distinguish them from those used by the first observer, may be denoted by the accented letters x', y', z', t'. If his observations also are to show light always to travel with the same velocity c in all directions, the equation of the wave front, as observed by him, must be:—

$$x'^2+y'^2+z'^2-c^2t'^2=0 \quad .. \quad .. \quad .. \quad (2)$$

A 19th-century mathematician would have insisted that x, y, z, t must necessarily be connected with x', y', z', t' by the simple relations:—

$$\left.\begin{aligned} x'&=x-ut \\ y'&=y \\ z'&=z \\ t'&=t \end{aligned}\right\} \quad .. \quad .. \quad .. \quad .. \quad (A)$$

Indeed, he would have been unable to imagine that there should be any other relation connecting these quantities. It is, however, obvious that if these relations hold, then equation (1) cannot transform into equation (2). Einstein showed that equation (1) will transform into equation (2) provided the co-ordinates x, y, z, t of the first observer are connected with the co-ordinates x', y', z', t' of the second observer by the equations:—

$$\left.\begin{aligned} x'&=\beta(x-ut) \\ y'&=y \\ z'&=z \\ t'&=\beta\left(t-\frac{vx}{c^2}\right) \end{aligned}\right\} \quad .. \quad .. \quad .. \quad (B)$$

where β stands for $\left(1-\frac{u^2}{c^2}\right)^{-\frac{1}{2}}$

To form some idea of the physical meaning of these equations, let us consider the simple case in which the first observer is at rest in the ether while the second moves through the ether with velocity u. The points of difference between equations (B) and (A) then admit of simple explanation. The factor β in the first of equations (B) is simply, according to the suggestion of Fitzgerald and Lorentz already mentioned, the factor according to which all lengths parallel to the axis of x must be adjusted on account of motion through the ether with velocity u. The moving observer must correct his lengths by this factor, and he must correct his times by the same factor in order that the velocity of propagation of light along the axis of x may still have the same velocity c; this explains the presence of the multiplier β in the last of equations (B). The one remaining difference between the two sets of equations, namely, the replacement of t in (A) by $t-\frac{ux}{c^2}$ in (B), represents exactly the want of synchrony which, as we have already seen, is to be expected in the observations of two observers whose velocity differs by a velocity u.

Although the equations admit of simple illustration by considering the case in which one observer is at rest in a supposed ether, it will be understood that the equations are more general than the illustration. They are in no way concerned with the possibility of an observer being at rest in an ether, or indeed the existence of an ether at all. Their general interpretation is this: If one observer O, having any motion whatever, finds, as a matter of observation, that light for him travels uniformly in all directions with a constant velocity c, then a second observer P, moving relative to O with a constant velocity u along the axis of x, will find, as a matter of observation, that light, for him also, travels uniformly in all directions with the same constant velocity c, provided he uses, for his observations, co-ordinates which are connected with the co-ordinates of O by equations (B).

This is the meaning that was attached to the equations by Einstein in 1905, but the equations had been familiar to mathematicians before this date. They had in fact been discovered by Lorentz in 1895 as expressing the condition that all electro-magnetic phenomena, including of course the propagation of light, should be the same for an observer moving through the ether with velocity u as for an observer at rest in the ether. For this reason the transformation of co-ordinates specified by these equations is universally spoken of as a "Lorentz transformation." What Einstein introduced in 1905 was not a new system of equations but a new interpretation of old equations. The two observers who used the co-ordinates x, y, z, t and x', y', z', t' had been regarded by Lorentz as being one at rest in an ether and one in motion with a velocity u; for Einstein they were observers moving with any velocities whatever subject to their relative velocity being u. Lorentz had regarded t as the true time and t' as an artificial time. If the observer could be persuaded to measure time in this artificial way, setting his clocks wrong to begin with and then making them gain or lose permanently, the effect of his supposed artificiality would just counterbalance the effects of his motion through the ether. With Einstein came the conception that both times, t and t', had precisely equal rights to be regarded as true time. The measure t' of time is precisely that which would be adopted naturally by any set of observers, or race of men, who disregarded their steady motion through space; their adoption of it would be above criticism if, as Einstein suggested, their motion through space had no influence on material phenomena, and it represents, as we have seen, the usual practice of astronomers in comparing time at different places. From this point of view neither measure of time is more accurate or more logical than the other. There are as many ways of measuring time as there are observers, and all are right.

The investigator who is trying to discover laws of nature will, in general, require to measure both time and space either directly or indirectly. If, to take a simple case, he is studying the motion of a single particle, he will measure out the position of the particle at definite instants as determined by his clock. He may specify the position of the particle at any instant by three measurements in space—for instance, he may say that two seconds after his particle started it was 6ft. to the E. of the point from which it

started, 9ft. to the N. and 12ft. vertically upward. The mathematician would express this by taking axes x, y, z to the E., to the N. and vertically upwards, and saying that at time $t=2$ the particle had co-ordinates $x=6$, $y=9$, $z=12$. Or he might, putting his time co-ordinate t on the same footing as the space co-ordinates x, y, z, simply say that $x=6$, $y=9$, $z=12$, $t=2$ represented one position of the particle. A complete set of readings of this type, each consisting of values of four co-ordinates, would give the complete history of the motion of the particle.

Such sets of simultaneous measurements form the common material of investigations in both pure and applied science. For instance, the engineer may measure the extension of a sample of steel corresponding to different loads; the electrician may measure the amount of light given by an electric filament corresponding to different amounts of current passed through it. In each of these cases there are only two quantities to be measured simultaneously, and an investigator can conveniently represent the result of the whole series of his measurements in graphical form; a single reading is represented by a point whose distances from two fixed perpendicular lines represent the quantities measured, and the curve obtained by joining these single points will give all the information contained in the whole set of readings.

We have seen that, in studying the motion of a particle in space, four sets of quantities must be measured, so that the results obtained cannot be plotted graphically on a piece of paper. Their proper representation demands a four-dimensional space, in which x, y, z and t are taken as co-ordinates. The practical importance of such graphical representation is *nil*, since it is impossible to construct a four-dimensional graph, but its theoretical importance to the theory of relativity is immense. For if the hypothesis of relativity is true, then the four-dimensional graphs of any natural event constructed by all observers, no matter what their relative motions, will be identical. The influence of their motion will be shown only in that the axes of x, y, z and t will be different for different observers, and the relations between these sets of axes will be those given by the foregoing equations (B).

The importance of this conception can hardly be overestimated, and it may be well to consider it further with the help of an illustrative example. Imagine a number of aeroplanes flying over England, and, in order to eliminate one of the three directions in space —the vertical—let us limit them to fly always at the same height, say 1,000ft. above sea-level. Imagine a number of similar plates of glass prepared, each marked faintly with an outline map of England and with lines of latitude and longitude. Suppose that at 12h.0m. G.M.T. a plate is taken and the position of each aeroplane marked by a thick black dot. At 12h. 1m. let a second plate be taken and similarly marked, and let this be done every minute for an hour. The 60 plates so marked will constitute a record of the motion of each aeroplane within this hour. If, now, we place the plates in order, one above the other, on a horizontal table, the mass of glass so formed will present a graphical representation, in three dimensions, of the motions of all the aeroplanes. In this graph the two horizontal co-ordinates represent motions in any two rectangular directions over England, say east and north, while the third co-ordinate—the vertical—represents time. The individual black dots which represent the positions of any one aeroplane will form a dotted curve, and this curve gives a graphical representation of the motion of the particular aeroplane. Our rectangle of glass contains the history, for one hour, of all the aeroplanes in graphical form.

To represent the motion of particles in the whole world of space a four-dimensional graph is required. The four-dimensional space in which it is constructed may, following the usual terminology, be spoken of as a four-dimensional continuum. The history of any particle in the universe—just as that of any aeroplane flying over England—will be represented by a continuous line in the continuum, and this is called the "world line" of the particle. If the hypothesis of relativity is true the same continuum and the same world lines will represent the history of the particles of the universe equally well for all observers, the influence of their motions being shown only through their choosing different axes in the continuum for their axes of space and time. Thus the continuum must be thought of as something real and objective, but the choice of axes is subjective and will vary with the observer, the relation between different choices being expressed mathematically by our equations (B), the equations of the Lorentz transformation. An inspection of these equations shows that the sets of axes chosen by different observers have different orientations in the continuum, so that what one observer describes as a pure space interval will appear to another to be a mixture of time and space.

The instant of time and point in space at which any event occurs can be fixed by a single point in the continuum, so that the interval between two events will be represented by a finite line. The events and the interval between them are absolute, but the interval will be split up into time and space in different ways by different observers. The interval between any two events, such as the great fire of London and the outburst on the star Nova Persei, may be measured by one set of observers as so many years and so many millions of miles, but another set of observers may divide the interval quite differently. For instance a terrestrial astronomer may reckon that the outburst on Nova Persei occurred a century before the great fire of London, but an astronomer on the Nova may reckon with equal accuracy that the great fire occurred a century before the outburst on the Nova. A third astronomer may insist that the events were simultaneous. All may be equally right, although none will be right in an absolute sense. At this stage we may notice one respect in which our pile of glass plates failed to represent the true continuum. The mass of glass was stratified into different plates which represent different times for one particular observer. To obtain a section which would represent what an observer in motion relative to this first observer could regard as simultaneous positions of the aeroplanes, we should have to cut the mass of glass on the slant. The continuum is more closely represented by our plates of glass if they are annealed into a solid mass from which all trace of the original stratification is made to disappear. All observers, no matter what their motion, are then equally free to cut a section to represent their individual ideas of simultaneity.

Thus space and time fade into subjective conceptions, just as subjective as right hand or left hand, front and behind, are in ordinary life. The continuum alone is objective and may be thought of as containing an objective record of the motion of every particle of the universe. The curve in which this record is embodied is spoken of as the world line of the particle in question. To use the words of Minkowski: "Space in itself and time in itself sink to mere shadows, and only a kind of union of the two retains an independent existence."

GRAVITATION AND RELATIVITY

Since all the phenomena of light and of electro-magnetism are believed, on almost incontrovertible evidence, to be in accordance with the hypothesis of relativity, it is necessarily impossible to determine absolute velocity by optical or gravitational means. On the other hand, as we have already mentioned, the Newtonian law of gravitation is readily seen to be inconsistent with the hypothesis of relativity. Three alternatives are open:—

(i.) The Newtonian law may be true, in which case it must be possible to determine absolute velocity by gravitational means.

(ii.) The Newtonian law may be untrue in its original form, but may become true when amended so as to conform to the relativity hypothesis.

(iii.) Neither of the foregoing possibilities may be true.

Alternative (i.) was explored by Sir Oliver Lodge, who, assuming the exact truth of the Newtonian law of gravitation, deduced that the observed motion of the perihelion of Mercury could be accounted for if the sun were moving through space with a velocity of about 70km. a second in a certain direction. This investigation had to be abandoned when Eddington pointed out that a similar discussion of the motions of the other planets would lead to vastly different values for the sun's velocity. Alternative (ii.) was explored by Einstein and others, but was found to lead to a motion of the perihelion of Mercury equal only to one-sixth part of that actually observed.

Alternative (iii.) remained with its innumerable possibilities.

Einstein commenced his attack on the problem by eliminating all possibilities which did not conform to two general principles. The first of these was the principle of relativity. Inasmuch as all physical phenomena except gravitation were believed to conform to this principle, it was natural to try, as a working hypothesis, the effect of assuming gravitation also to conform. The second principle was the so-called principle of equivalence, and this demands a word of explanation.

To our children we explain that an apple falls to the ground because a force of gravitation inherent in the earth's mass impels the apple towards the centre of the earth. Most schoolboys know that this is not quite the whole story; the path of the apple is more accurately determined by supposing the apple to be acted on simultaneously by two forces—a gravitational force of attraction towards the earth's centre and the centrifugal force arising from the earth's rotation. It is only because the earth's rotation is comparatively slow that the conception of an attraction towards the earth's centre gives a tolerably plausible account of the fall of the apple. If the earth rotated at 17 times its present rate objects would not fall, even approximately, towards the earth's centre; they would fall always parallel to the earth's axis, and the inhabitants of the northern hemisphere might explain this as arising from a force of repulsion inherent in the pole star. If the earth rotated many times faster even than this, bodies would fall always perpendicularly away from the earth's axis, and this might be interpreted as arising from a gravitational repulsion residing in the earth's axis.

These illustrations will show that it is easy to confuse acceleration arising from the earth's rotation with gravitational attraction. We may go further and say that it is impossible to distinguish between the effects of gravitational attraction and the effects of acceleration of any kind whatever. Every aviator knows this to his sorrow; it is inherently impossible to devise any instrument which shall show the direction of the vertical in an aeroplane, since an acceleration of the aeroplane produces on any instrument whatever, effects which are indistinguishable from those of gravity. From such considerations Einstein was led to his principle of equivalence, which may be enunciated as follows:—

"A gravitational field of force at any point of space is in every way equivalent to an artificial field of force resulting from acceleration, so that no experiment can possibly distinguish between them."

Guided by these two principles—relativity and equivalence—Einstein was led to the view that all gravitational "fields of force" must be illusions. The apparent "force" arises solely from acceleration and there is no other kind of gravitational force at all. In this statement, as in the statement of the principle of equivalence above, the word acceleration is used in its widest sense. Acceleration results not only from change in the amount of a velocity, but from a change in its direction also. For instance a motor-cyclist riding in a circle at a uniform speed of 60 miles an hour will be the subject of an acceleration towards the centre of the circle. He knows that the apparent force so produced is just as real in its effects as gravitation, and to save himself from falling as a result of its influence he must incline the direction of his machine to the vertical.

It is clear that the acceleration or curvature of path which figures as gravitation cannot be an acceleration or curvature in ordinary three-dimensional space. Before the apple starts to fall from the tree there is neither acceleration nor curvature, and yet the apple is undoubtedly acted on by gravitation. Moreover, this three-dimensional space is, as we have seen, different for different observers—it is a subjective and not an objective conception, and the gravitation resulting from such a curvature could not conform to the relativity condition. Einstein was accordingly led to suppose that gravitation arose from curvature in the four-dimensional space, or continuum, in which time formed the fourth dimension. This continuum, as has been seen, is objective and if the path of the particle can also be made objective, the resulting gravitation will conform to the relativity principle. The path of the particle in the continuum is, however, simply its "world line," which we have already had under discussion. This world line is determined by natural laws, and if these are to be objective the specification of the world line must also be objective. There is, however, only one specification of world lines in the continuum which is objective in the sense that the same specification will give the same world lines to observers moving with different velocities. It is that every world line must be so drawn as to represent the shortest path between any two points on it. Mathematically, lines which satisfy this condition are known as *geodesics*. Thus Einstein was led to suppose that world lines must be geodesics in the four-dimensional continuum.

Consider for a moment a page of this volume as presenting a two-dimensional analogy of the continuum. The shortest distance between any two points is of course the straight line joining them, so that the geodesics are simply straight lines. These possess no curvature of path, and if they formed a true analogy to the geodesics in the continuum there could clearly be no explanation of gravitation of the type we have been contemplating. There is, however, another type of two-dimensional surface. It is represented by the surface of a solid body such as a sphere—say the earth. On the earth's surface the geodesics are the great circles; every mariner or aviator who desires to sail the shortest course between two points sails along a great circle. To take a definite instance, the shortest course from Panama to Ceylon is not along the parallel of lat. (about 9°N.) which joins them—the aviator who wishes to fly the shortest course between the two countries will fly north-east from Panama, he will pass over England and finally reach Ceylon from the north-west. The reader may rapidly verify this by stretching a thread tightly over the surface of an ordinary geographical globe. Let him now trace out the course on an ordinary Mercator chart, and it will be found to appear very curved indeed—the course of the aviator will look surprisingly like that of a comet describing an orbit under the attraction of a sun situated somewhere near the middle of the Sahara.

The reader who performs these simple experiments will understand how Einstein was led to suppose that gravitation could be explained by a curvature inherent in the continuum. The world lines of particles are geodesics but the space itself, so to speak, provides the curvature. The curvature of path is thrust upon the particle by the nature of the continuum, but we, who until recently have been unaware even of the existence of the continuum, have been tempted to ascribe it to the action of a special agency which we have invented *ad hoc* and called "gravitation." According to Einstein's view of the nature of gravitation, it is no more accurate to say that the earth attracts the moon than to say that the pockets of an uneven billiard table attract or repel the balls.

Perhaps this train of thought may seem artificial. If so, the reason is that we have not been able to explore the other possibilities which have branched off our main line of thought. In point of fact, Einstein found himself practically limited to the conclusion we have stated. Not only so, but the actual type and degree of curvature in the continuum prove to be uniquely fixed in terms of the masses of the gravitating bodies. Thus Einstein, knowing the mass of the sun, found himself in a position to predict absolutely what the motion of the perihelion of Mercury must be. It was found to be 42·9″ a century, a figure which agreed with observation to well within the limits of error of the observations. The motions of the other planets as predicted by the theory of relativity, have also been found to agree with those observed to within the errors of observation. This latter test is not a very stringent one, since the departures from the motion predicted by the Newtonian law are too small to admit of very precise measurement.

Effect of Gravitation on Light.—Einstein's theory requires that the world line of a ray of light also shall be a geodesic in the continuum. In interstellar space and regions remote from gravitating masses, this merely means that light travels in straight lines. But a star or other massive body distorts the continuum in its neighbourhood by an amount which is proportional to its mass. In the neighbourhood of such a body a ray of light does not travel in a straight line; it is deflected by the gravitational field of the body by an amount which is directly proportional to the mass of the body, and also, of course, depends on how closely

the ray approaches the body. Einstein calculated that a ray of light which comes from a distant star and passes near the edge of the sun on its journey must be bent, in its passage past the sun, by an angle which should be 1·745″ if the ray just grazes the sun, and would be less, in proportion to the inverse distance from the centre of the sun, for other rays.

The observatories of Greenwich and Cambridge despatched expeditions to test this prediction at the eclipse of 1919. It was found that the stars which appeared near to the sun at the instant of eclipse showed an appreciable displacement, as compared with their normal positions, of the type required by Einstein's theory. Exact measurement confirmed that the displacement varied approximately as the inverse distance from the sun, and that the displacement at the limb was sensibly equal to Einstein's predicted value of 1·745″. The Cambridge observers, hampered by cloudy weather, obtained for this quantity the value 1·61″ but with a probable error of 0·30″. The Greenwich observers obtained a value of 1·98″ with a probable error of 0·12″, but Prof. H. N. Russell subsequently pointed out that their photographs contained intrinsic evidence of a horizontal and vertical scale difference of the order of one part in 12,000 almost certainly due to a distortion of the coelostat mirror under the sun's rays, and if the measures are corrected for this the result is brought much closer to the theoretical prediction. Three years later an expedition, sent out by Lick observatory to observe the 1922 eclipse, was favoured by good weather and obtained for the displacement at the sun's limb, a value of 1·72″ with a probable error of 0·11″. None of the expeditions had of course measured the deflections of stars actually at the sun's limb; most of the stars were several diameters away from the limb, the observed deflections being corrected so as to bring them to the limb. The deflections of stars at all distances were found to agree well with the predictions of Einstein's theory.

The Gravitational Shift of Spectral Lines.—The theory makes one further prediction which admits of experimental test. The atoms of any element, say calcium, may be supposed to be formed according to a definite specification, the terms of which depend neither on the velocity of a particular observer nor on his position relative to the gravitational fields of the universe. It can be deduced that the light received from a calcium atom situated in the intense gravitational field near the sun's surface ought to be of slower period, and therefore of redder colour, than the similar light emitted by terrestrial atoms. To be more precise, the Fraunhofer lines in the solar spectrum ought to show a displacement to the red; this displacement ought to be homologous, and should be of amount 0·008 Å units at the cyanogen band λ 3883 at which observations have been chiefly made. Early attempts to test this prediction led to strangely discordant results. All observers found some effect of the kind predicted, but its amount was generally substantially less than the predicted amount, varying from almost *nil* (St. John, 1917) to nearly the full amount to be expected (Evershed, 1918 and 1923, Grebe and Bachem, 1919). The latest measurements of the displacement are those of Evershed (1927). Measuring the mean displacement shown by the lines of 29 prominences, Evershed found that the H and K lines of calcium showed the same mean displacement of 0·009 Å, as compared with 0·008 Å required by theory.

The want of success of the earlier observations is explained by the circumstance that the relativity shift of 0·008 Å is liable to be masked by larger shifts of uncertain amount arising from other causes. Larger shifts would be expected in stars which were of larger mass than the sun or of smaller radii. Many known stars have masses far larger than the sun, but they also have larger radii, and so ought to show only about the same spectral shift as the sun. On the other hand the class of stars known as "white dwarfs" have masses comparable with that of the sun, but far smaller radii. For instance, calculation shows that the companion to Sirius, a star whose radius is only about $\frac{1}{55}$ of that of our sun, ought to show a shift of as much as 0·30 Å. On putting the matter to the test at Mount Wilson observatory, W. S. Adams found an actual shift of 0·32 Å. It is hardly possible any longer to doubt that the spectral shift predicted by Einstein really exists.

ELECTRO-MAGNETIC FORCES

The restricted physical theory of relativity introduced a revolution into the foundations of scientific thought by destroying the objectivity of time and space. The gravitational theory has effected a hardly less important revolution by destroying our belief in the reality of gravitation as a "force." The physicist has, however, to deal with other "forces" besides those of gravitation, namely, the electro-magnetic forces which are concerned in all electrical, magnetic and chemical phenomena, and the question inevitably arises as to whether these also must be regarded as illusions, arising only from our faulty interpretation of the special metrical properties of the continuum. Analysis makes it clear that the continuum as imagined by Einstein has no capacity for simulating any forces beyond those of gravitation. If electro-magnetic forces are evidence of special geometrical properties of the continuum, then the continuum is more complicated even than Einstein imagined.

In a brilliant paper published in 1918 (*Berlin Sitzungsber.*, 1918, p. 465) H. Weyl proved that Einstein's geometry is far from being the most general geometry which is consistent with the general principle of relativity, and showed that certain at least of the forces of electro-magnetism could be explained very naturally by adding an extra degree of complexity to the geometry of the continuum. In the continuum as imagined by Einstein, the length of a measuring rod might change as it was moved about in a gravitational field, but its length at any instant would depend solely on its position in space. Weyl imagined a continuum in which it is meaningless to speak of comparing two lengths at different points; we can compare two lengths at the same point, such as two measuring rods pointing in different directions at the same place, but we can only measure a length by comparison with a standard length already in existence at the point at which the measurement is made. The standard length was peculiar to the point at which it existed, so that Weyl had to imagine the whole of the continuum, every point of space at every instant of time, filled with an infinite series of gauges against which a moving object might be measured. Whether the length of a measuring rod changed as it was moved about would now of course depend on whether the arbitrary selection of gauges had been arranged so as to make it change or so as to keep it constant.

We might, for instance, select the yard as unit length in London, and the metre in Paris. In this case a standard yard transferred to London from Paris might be said to shrink by about a tenth of its length. Suppose now that two standard yards are taken from London to Paris. When we compare them with the standard length at Paris they may both be said to have shrunk, but if we compare them with one another in Paris—and this is possible, even in Weyl's geometry—we may expect to find them both of the same length. If they appear to have shrunk when measured against the Paris unit of length, they have at least shrunk equally.

Imagine first that the two standard yards travel from London to Paris lying side by side in the same box, so that they pass through the same experiences on their journey. If physical changes are governed by a law of causation, so that similar causes always produce the same effects, then the two rods will necessarily have the same length when they arrive in Paris.

Suppose, however, that one standard travelled via Calais and one via Havre. The two rods have now been subjected to different influences on their journey, and there is no *a priori* reason why their lengths should not be different when they arrive in Paris. Weyl's geometry expects, as a matter of course, that their lengths will be different, at least until the contrary is proved. And if the length of one proves to be 0·9143 metres, while that of the other proves to be 0·9144 metres, Weyl's geometry would merely interpret this as evidence that the two rods had travelled by different routes.

The practical working physicist, confronted with two rods which were of equal lengths when they left London, but of different lengths when they reached Paris, would also conclude that they had travelled by different routes, or at least had experienced different physical conditions on their journey. If the measured

rods had travelled side by side packed in the same box he would find the difference in length inexplicable; for why, he would say, if one has shrunk, did not the other shrink by an equal amount. But he would consider the difference in length quite natural if they had travelled by different routes. One might have passed through a succession of heatings and coolings so that fatigue-phenomena had permanently changed its molecular structure, or might have experienced a series of magnetic changes so that hysteresis had affected its length.

The foregoing elementary considerations will show why Weyl's geometry, which attempts to take account of physical forces, and so of varying physical conditions, must necessarily break away from Einstein's geometry, which took no cognizance of physical changes. On Einstein's scheme a measuring rod, or any other piece of matter, had a standard physical state which it eternally carried about with it; it could not expand with heat or contract with cold, and its physical condition did not enter into the discussion at all.

Weyl begins, in effect, by supposing, quite generally, that moving a rod through a small distance will produce a small change in its length, the amount of this change depending on the physical conditions in the small region through which the rod is moved. Any motion of a measuring rod is represented by a world line in the four-dimensional space time continuum. Taking x, y, z as co-ordinates of space and t as time co-ordinate, a small journey, or a small piece of the world line of the measuring rod, will be represented by small changes dx, dy, dz, dt in the values, x, y, z, t. Weyl supposes that this small journey produces a change dl in the length of the rod, l, given by

$$dl = l(\mathrm{F}dx + \mathrm{G}dy + \mathrm{H}dz + \mathrm{K}dt)$$

The factor l occurs outside because the change dl must necessarily be proportional to the length l of the rod; F, G, H and K then depend only on the conditions prevailing at the point $x\ y\ z\ t$ of the continuum, *i.e.*, on the physical conditions in the region occupied by the rod at the instant when the journey is performed.

If two rods move over the same journey, say from London to Paris, and one is found to be slightly longer than the other by a factor $(l - \theta)$ when the two are compared at the end of the journey, it is easily shown that

$$\theta = \int(\mathrm{F}dx + \mathrm{G}dy + \mathrm{H}dz + \mathrm{K}dt)$$

The world lines of the two rods intersect twice, first in London at the beginning of the journey, and again in Paris at the end of the journey. The above integral must be taken round a complete circuit in the four-dimensional continuum, starting from Paris, retracing the journey of the first rod to London, and then starting out again from London and following the route of the second rod to Paris.

The condition that the two rods shall be of the same length when they reach Paris is that $\theta = 0$, or that the integrand $\mathrm{F}dx + \mathrm{G}dy + \mathrm{H}dz + \mathrm{K}dt$ shall be a perfect differential. The conditions for this are expressed by the six equations:—

$$\frac{\delta \mathrm{H}}{\delta y} - \frac{\delta \mathrm{G}}{\delta x} = 0, \text{ etc.}; \quad \frac{\delta \mathrm{K}}{\delta x} - \frac{\delta \mathrm{F}}{\delta t} = 0, \text{ etc.}$$

Compare these with Maxwell's equations for the components (α, β, γ) of magnetic force and the components (x, y, z) of electric force, namely

$$\frac{\delta \mathrm{H}}{\delta y} - \frac{\delta \mathrm{G}}{\delta x} = \alpha, \text{ etc.}; \quad -\mathrm{C}\frac{\delta \Psi}{\delta x} - \frac{\delta \mathrm{F}}{\delta t} = \mathrm{C}X, \text{ etc.}$$

where F, G, H are the components of the magnetic vector-potential, Ψ is the electrostatic potential, and C is the velocity of light. We at once see that if we identify the F, G, H and K which specify the change of length of the measuring rod with Maxwell's F, G, H and $-\mathrm{C}\Psi$, then the condition that θ, the relative change of length, shall be zero, is identical with the condition that all the electric and magnetic forces are zero, so that there is no electro-magnetic field. When this condition is satisfied Weyl's geometry becomes identical with that of Einstein. Since θ is now always zero, the length of a given measuring rod depends only on its position in space and time, and not on the route by which it attained that position, this being a fundamental consequence of Einstein's scheme.

Weyl's extension of Einstein's scheme consists in introducing the four quantities we have denoted by F, G, H and K, and identifying them with Maxwell's F, G, H and $-\mathrm{C}\Psi$. This is equivalent, as we have just seen, to introducing the magnetic forces α, β, γ and the electric forces X, Y, Z into his geometry. It is now possible to explain all electro-magnetic phenomena in free space in terms of geometry, for all such phenomena can be deduced from Maxwell's equations.

Einstein's theory of gravitation differed slightly from that of Newton, and so predicted slightly different phenomena. These slight differences made direct experimental tests between the two theories possible and these were found to decide in favour of Einstein. Weyl's theory, on the other hand, is formally identical with that of Maxwell, and so predicts precisely the same phenomena in free space. For this reason no experimental test between the two theories is possible.

In 1921 Eddington extended Weyl's geometry into a still more general system of geometry, in which even lengths at the same point were not assumed to be capable of direct comparison. This geometry had a certain advantage over Weyl's original geometry in that the terms which were ultimately called on to explain electro-magnetic phenomena occurred naturally as a necessary development of the geometry. In Weyl's geometry the necessary terms are shaped to fill a gap, and it is then found that they fit exactly. In Eddington's geometry no shaping is necessary, or, rather, the shaping process is performed off the stage or before the curtain rises. The gravitational and electro-magnetic forces are accounted for by the symmetrical and antisymmetrical parts of a single tensor, so that an electro-magnetic field appears almost to be a necessary accompaniment to a gravitational field. But Eddington's geometry, like that of Weyl, predicts precisely the same phenomena as Maxwell's classical electro-magnetic theory, so that again experimental test is impossible.

Both these geometries are successful in interpreting the electro-magnetic field in free space in terms of geometry, but show less success in interpreting the ponderomotive forces on charged bodies, electrons, protons, etc. The difficulty is not that they cannot explain the observed forces, but that they do not explain them in a simple, natural way, and that they explain too much. Although nothing less than the proposed geometries would have sufficed to explain the electro-magnetic field in free space, it looks as if something less would be adequate to explain the ponderomotive forces exerted by the field on its own electric charges. The proposed geometries are too rich and predict not only observed phenomena but also others which have then to be explained away as being incapable of observation.

After making great advances in the direction of clearing away these difficulties, Einstein washed his hands of the whole attempt in 1926.

Later Einstein proposed a scheme based on a geometry fundamentally different from either of the foregoing, which he describes as the "Unitary Field Theory." His main object is to avoid the dualism by which the gravitational field and the electro-magnetic field were exhibited in former theories as independent constructions in the space-time continuum, and instead to display "both types of field as manifestations of one comprehensive type of spatial structure in the space-time continuum." The new theory resulted from the discovery that types of geometry exist in which distant lines may be parallel, but in which lengths in the neighbourhood of a point obey laws of measurement of the same type (Riemannian) as in the simple purely gravitational theory, so that the geometry is not Euclidean. The new geometry has been described as a geometry in which there can be parallels but not parallelograms; if we attempt to draw a figure which is to have pairs of equal and parallel lines as its opposite sides, we find that the parallelogram we are attempting to build refuses to close up at its fourth corner. So far Einstein has developed the consequences of his "Unitary Field Theory" to a first approximation only. The new theory obviously escapes some of the reproaches which have been brought against its predecessors; whether it has any claims to finality remains to be seen.

The Position of the Ether.—It is clear that the doctrine of relativity must profoundly affect our views of the ether and its function in the scheme of the universe. At one stage in the history of science, there was a tendency to imagine space filled with innumerable ethers, to the extent almost of one ether for every set of phenomena requiring explanation. That stage passed, and by the end of the 19th century only one ether received serious consideration, the so-called electro-magnetic ether of Faraday and Maxwell. This ether gave a plausible mechanical explanation of electrostatic phenomena, although it was more than doubtful whether it could account for the electro-magnetic phenomena from which it took its name, and it was comparatively certain that it could not account for gravitation. It gave, however, a satisfactory explanation of the propagation of waves of light—they were simply waves in the ether which travelled with an absolute velocity c determined once and for all by the structure of the ether. On this view it was quite certain that an observer moving through the ether with a velocity u would measure the velocity of light travelling in the same direction as himself as $c-u$. Relativity, teaching that this velocity is always precisely c, dismisses the particular type of ether imagined by Faraday and Maxwell. Whether any new ether will be devised to replace it remains to be seen, but none appears to be necessary. Any ether which can be imagined would appear to depend upon an objective separation of time and space. Relativity does not deny that such an objective separation may, in the last resort, really exist, but it shows that no material phenomena are concerned with such a separation. By a very slight turn of thought, the primary postulate of relativity may be expressed in the form that the material world goes on as though no ether existed.

To the relativist the essential background to the picture of the universe is not the varying agitation of a sea of ether in a three-dimensional space but a tangle of world lines in a four-dimensional space. Only the intersections of the world lines are important. An intersection at a point in the continuum represents an event, while the part of a world line which is free from intersections represents the mere uneventful existence of a particle or a pulse of light. And so, since our whole knowledge of the universe is made up of events, it comes about that the tangle of world lines may be distorted and bent to any degree we please; so long as the order of the intersections is not altered, it will still represent the same universe. Thus the last function of the ether, that of providing a scale of absolute measurements in space, becomes a superfluity. To the physicist who urges that space measurements without an underlying ether become meaningless, the relativist can reply that time-measurements without an underlying "time-ether" are equally meaningless. A "time-ether" has never been regarded as a necessity, and the relativist may fairly argue that the "space-ether" has no greater claim to retention.

Probably, however, final judgment on this, as on other similar questions, must be suspended until the position of electro-magnetic forces in the general scheme of relativity is better understood than it is now.

COSMOLOGY

According to the simple views of space and time which prevailed before the advent of relativity, time had no properties except duration, and space had no properties except extension. Every instant of time was, in its essence, precisely similar to every other instant of time, so that time must go on forever unless it was stopped by something different from time; it could not end of itself, for this would require the last instant of time to have different properties from all other instants of time. Similarly all elements of space were supposed to be intrinsically of the same nature and thus required that space should extend to infinity in all directions unless it were abruptly ended by something that was not space.

Einstein's theory of relativity changed all this. According to this theory the space-time in the neighbourhood of a gravitating mass is essentially different from space-time which is far away from all masses; the former is curved, while the latter, at least if all gravitating masses are infinitely far away, is not. The curvature of the space-time in the neighbourhood of the sun causes the planets to describe ellipses, whereas if all masses were infinitely removed, they would describe straight lines. When it is once admitted that all elements of space-time are not intrinsically similar, no reason remains either why space should be of infinite extent or why time should be of infinite duration.

On Einstein's theory, the curvature of space-time at any point of the continuum is proportional to the value of the gravitational potential at the point. To calculate this we must take the different masses of the universe in turn, divide each by its distance from the point in question, and add together the quotients so obtained. When this is done it is found that, unless there happens to be a large mass very near to the point, distant stars and masses contribute far more to the gravitational potential than near ones. The distant masses have to be divided by a greater distance, but are so much more numerous than the near masses that their greater numbers more than compensate for their distance. Accordingly, except in the near neighbourhood of massive bodies, the curvature of the continuum is determined by the distant masses of the universe, and there will be a regular and continuous field of curvature, disturbed only in the neighbourhood of massive bodies, by the additional curvature impressed by these bodies. An analogy in two dimensions is provided by the spherical surface of the earth, which we may imagine to be deformed here and there by mole-hills or other small undulations; these correspond to the local curvatures which are impressed on the general curvature of space by the proximity of massive bodies.

When our ancestors found that the earth's surface was curved it was natural for them to suppose that its curvature bent it round into a closed surface, so that a traveller continually following a straight path could come back to his starting point. The earth might have been shaped like a saucer or a basin, but it was much simpler and more natural to suppose it to be spherical. In the same way when the space-time continuum is found to be curved with a fairly uniform curvature, it is natural to conjecture that this curvature of itself closes the continuum and so reduces it to finite dimensions. There still remain innumerable different ways in which this can be effected.

The general curvature of the continuum at any point is determined by the distant masses of the universe, so that if space is closed, the volume of this space and the distribution of masses inside it must determine its curvature at every point. The curvature in turn fixes the volume and this will not be the volume from which we started unless the masses are of exactly the right amount. Thus we see that a universe of given size requires masses of a certain amount to maintain it at this size, and, conversely, given masses require a universe of a certain definite size in which to exist. In the simplest case in which the matter is supposed to be spread uniformly throughout the universe, the total mass of the universe is proportional to its radius, or, what is the same thing, both the mass and the radius of the universe vary inversely as the square root of the density of the matter. Thus a great amount of matter requires a large universe in which to exist, and exists in this universe in a highly attenuated state, whereas a small amount of matter must have a small universe in which it exists in a state of high density.

De Sitter attempted in 1917 to calculate the radius of the universe from the observed mean density of matter, but his estimate for this observed mean density, namely, 10^{-26} was probably far too high. In 1926 Hubble estimated the mean density of matter in space to be of the order of $1{\cdot}5 \times 10^{-31}$ grammes per cubic centimetre, and calculated the radius of the universe to be $8{\cdot}5 \times 10^{28}$ centimetres or 88,000 million light years. This is about 600 times the greatest distance at which spiral nebulae are visible in the great 100-inch telescope at Mount Wilson, so that we may say that the range of vision of this telescope is one six-hundredth part of the radius of the universe. The mass corresponding to this size of universe is $1{\cdot}8 \times 10^{57}$ grammes or about 900,000 million million million times the mass of the sun.

These calculations have been made on the supposition that, apart from local irregularities, the curvature of space is the same everywhere so that space is spherical; this is consistent with the

assumption that the mean density of matter has a uniform value throughout space.

There is no reason why space should not, to an approximation, be spherical, but it is unlikely that the whole continuum can be. The cross-section of the continuum which corresponds to a given instant of time is the spatial universe at that instant, and if the continuum were spherical, this cross-section would be of ever-varying size, so that the mass of the universe would have to vary continually.

For this and other reasons Einstein imagines the continuum to be cylindrical as regards its extension in time, but spherical as regards its extension in space, so that cross-sections at different instants always give a spherical universe of constant size and so of constant mass.

To avoid the difficulty of writing and reading in terms of four-dimensional time-space, let us abstract two dimensions from space, so that the continuum becomes two-dimensional, one dimension representing space and the other representing time. The axis of time may be conveniently supposed to be vertical, the past being down below and the future up above. A horizontal cross-section will give the state of the universe at any instant; this horizontal cross-section will consist of a line, on which all the particles of the universe will lie; we may think of them as beads on a wire, capable only of motion backwards and forwards along the wire.

In terms of this simplified scheme, the primitive cosmology of pre-relativity days would represent the continuum by a plane which extended to infinity in all directions, both of space and time. In accordance with Newton's first Law of Motion the world lines of particles are straight lines in the plane, except in so far as the particles are compelled by impressed "forces" to depart from these straight lines. It is convenient to take as unit of length the distance travelled by light in the unit of time, so that unless the particles move with velocities comparable with that of light, their world lines are approximately parallel to the axis of time, and so are nearly vertical. The world lines of rays of light are straight lines inclined at angles of 45° to the vertical.

Einstein's cosmology replaces this plane by a right circular cylinder, whose axis is the axis of time. The world lines of particles whose velocity is small compared with that of light are vertical lines on this cylinder. The world line of a ray of light is a helix which travels round and round the cylinder, always making an angle of 45° with the horizontal. This meets the world line of a particle an infinite number of times at intervals of time apart, each of which represents the time taken for light to travel completely round the universe. A consequence, which is of greater interest theoretically than practically, is that an observer would see an infinite number of images of every star, exhibiting its state at successive epochs in its development, these being separated by the time taken for light to travel round the universe.

De Sitter has proposed a modification of Einstein's cosmology which is free from this last feature. He replaces Einstein's cylinder by a hyperboloid of one sheet on which the rectilinear generators are inclined at an angle of 45° to the vertical. These rectilinear generators now represent the paths of rays of light, while the world lines of particles are hyperbolae, which are nearly in vertical planes provided that the velocities of the particles are small in comparison with that of light. In this scheme the world lines of a particle and of a light ray only intersect once. De Sitter's scheme requires that the distances of particles from one another should increase with the progress of time, so that the relative velocities of pairs of objects in the universe ought to be mainly velocities of recession. With few exceptions the spectra of the spiral nebulae are observed to show a strong displacement of their lines towards the red. This is generally interpreted as evidence of a velocity of recession which appears to average some 700km. a second, and if this is the true interpretation, it obviously lends some support to De Sitter's scheme of cosmology.

Modifications of the schemes of Einstein and De Sitter have been proposed by Weyl and Lanczos, but astronomical observation has so far provided no means either of deciding between the original schemes or between the proposed modifications.

RELATIVITY: PHILOSOPHICAL CONSEQUENCES. Of the consequences in philosophy which may be supposed to follow from the theory of relativity (*q.v.*), some are fairly certain, while others are open to question. There has been a tendency, not uncommon in the case of a new scientific theory, for every philosopher to interpret the work of Einstein in accordance with his own metaphysical system, and to suggest that the outcome is a great accession of strength to the views which the philosopher in question previously held. This cannot be true in all cases; and it may be hoped that it is true in none. It would be disappointing if so fundamental a change as Einstein has introduced involved no philosophical novelty. (*See* SPACE-TIME.)

Space-time.—For philosophy, the most important novelty was present already in the special theory of relativity; that is, the substitution of space-time for space and time. In Newtonian dynamics, two events were separated by two kinds of interval, one being distance in space, the other lapse of time. As soon as it was realised that all motion is relative (which happened long before Einstein), distance in space became ambiguous except in the case of *simultaneous* events, but it was still thought that there was no ambiguity about simultaneity in different places. The special theory of relativity showed, by experimental arguments which were new, and by logical arguments which could have been discovered any time after it became known that light travels with a finite velocity, that simultaneity is only definite when it applies to events in the same place, and becomes more and more ambiguous as the events are more widely removed from each other in space.

This statement is not quite correct, since it still uses the notion of "space." The correct statement is this: Events have a four-dimensional order, by means of which we can say that an event A is nearer to an event B than to an event C; this is a purely ordinal matter, not involving anything quantitative. But, in addition, there is between neighbouring events a quantitative relation called "interval," which fulfils the functions both of distance in space and of lapse of time in the traditional dynamics, but fulfils them with a difference. If a body can move so as to be present at both events, the interval is time-like. If a ray of light can move so as to be present at both events, the interval is zero. If neither can happen, the interval is space-like. When we speak of a body being present "at" an event, we mean that the event occurs in the same place in space-time as one of the events which make up the history of the body; and when we say that two events occur at the same place in space-time, we mean that there is no event between them in the four-dimensional space-time order. All the events which happen to a man at a given moment (in his own time) are, in this sense, in one place; for example, if we hear a noise and see a colour simultaneously, our two perceptions are both in one place in space-time.

When one body can be present at two events which are not in one place in space-time, the time-order of the two events is not ambiguous, though the magnitude of the time-interval will be different in different systems of measurement. But whenever the

interval between two events is space-like, their time-order will be different in different equally legitimate systems of measurement; in this case, therefore, the time-order does not represent a physical fact. It follows that, when two bodies are in relative motion, like the sun and a planet, there is no such physical fact as "the distance between the bodies at a given time"; this alone shows that Newton's law of gravitation is logically faulty. Fortunately, Einstein has not only pointed out the defect, but remedied it. His arguments against Newton, however, would have remained valid even if his own law of gravitation had not proved right.

The fact that time is private to each body, not a single cosmic order, involves changes in the notions of substance and cause, and suggests the substitution of a series of events for a substance with changing states. The controversy about the ether thus becomes rather unreal. Undoubtedly, when light-waves travel, events occur, and it used to be thought that these events must be "in" something; the something in which they were was called the ether. But there seems no reason except a logical prejudice to suppose that the events are "in" anything. Matter, also, may be reduced to a law according to which events succeed each other and spread out from centres; but here we enter upon more speculative considerations.

Physical Laws.—Prof. Eddington has emphasised an aspect of relativity theory which is of great philosophical importance, but difficult to make clear without somewhat abstruse mathematics. The aspect in question is the reduction of what used to be regarded as physical laws to the status of truisms or definitions. Prof. Eddington, in a profoundly interesting essay on "The Domain of Physical Science," states the matter as follows:—

> In the present stage of science the laws of physics appear to be divisible into three classes—the identical, the statistical and the transcendental. The "identical laws" include the great field-laws which are commonly quoted as typical instances of natural law—the law of gravitation, the law of conservation of mass and energy, the laws of electric and magnetic force and the conservation of electric charge. These are seen to be identities, when we refer to the cycle so as to understand the constitution of the entities obeying them; and unless we have misunderstood this constitution, violation of these laws is inconceivable. They do not in any way limit the actual basal structure of the world, and are not laws of governance (*op. cit.*, pp. 214–215).

It is these identical laws that form the subject-matter of relativity theory; the other laws of physics, the statistical and transcendental, lie outside its scope. Thus the net result of relativity theory is to show that the traditional laws of physics, rightly understood, tell us almost nothing about the course of nature, being rather of the nature of logical truisms.

This surprising result is an outcome of increased mathematical skill. As the same author says elsewhere:—

> In one sense deductive theory is the enemy of experimental physics. The latter is always striving to settle by crucial tests the nature of the fundamental things; the former strives to minimise the successes obtained by showing how wide a nature of things is compatible with all experimental results.

The suggestion is that, in almost any conceivable world, *something* will be conserved; mathematics gives us the means of constructing a variety of mathematical expressions having this property of conservation. It is natural to suppose that it is useful to have senses which notice these conserved entities; hence mass, energy, and so on *seem* to have a basis in our experience, but are in fact merely certain quantities which are conserved and which we are adapted for noticing. If this view is correct, physics tells us much less about the real world than was formerly supposed.

Force and Gravitation.—An important aspect of relativity is the elimination of "force." This is not new in idea; indeed, it was already accepted in rational dynamics. But there remained the outstanding difficulty of gravitation, which Einstein has overcome. The sun is, so to speak, at the summit of a hill, and the planets are on the slopes. They move as they do because of the slope where they are, not because of some mysterious influence emanating from the summit. Bodies move as they do because that is the easiest possible movement in the region of space-time in which they find themselves, not because "forces" operate upon them. The apparent need of forces to account for observed motions arises from mistaken insistence upon Euclidean geometry; when once we have overcome this prejudice, we find that observed motions, instead of showing the presence of forces, show the nature of the geometry applicable to the region concerned. Bodies thus become far more independent of each other than they were in Newtonian physics: there is an increase of individualism and a diminution of central government, if one may be permitted such metaphorical language. This may, in time, considerably modify the ordinary educated man's picture of the universe, possibly with far-reaching results.

Realism in Relativity.—It is a mistake to suppose that relativity adopts an idealistic picture of the world—using "idealism" in the technical sense, in which it implies that there can be nothing which is not experience. The "observer" who is often mentioned in expositions of relativity need not be a mind, but may be a photographic plate or any kind of recording instrument. The fundamental assumption of relativity is realistic, namely, that those respects in which all observers agree when they record a given phenomenon may be regarded as objective, and not as contributed by the observers. This assumption is made by common sense. The apparent sizes and shapes of objects differ according to the point of view, but common sense discounts these differences. Relativity theory merely extends this process. By taking into account not only human observers, who all share the motion of the earth, but also possible "observers" in very rapid motion relatively to the earth, it is found that much more depends upon the point of view of the observer than was formerly thought. But there is found to be a residue which is not so dependent; this is the part which can be expressed by the method of "tensors." The importance of this method can hardly be exaggerated; it is, however, quite impossible to explain it in non-mathematical terms.

Relativity Physics.—Relativity physics is, of course, concerned only with the quantitative aspects of the world. The picture which it suggests is somewhat as follows:—In the four-dimensional space-time frame there are events everywhere, usually many events in a single place in space-time. The abstract mathematical relations of these events proceed according to the laws of physics, but the intrinsic nature of the events is wholly and inevitably unknown except when they occur in a region where there is the sort of structure we call a brain. Then they become the familiar sights and sounds and so on of our daily life. We know what it is like to see a star, but we do not know the nature of the events which constitute the ray of light that travels from the star to our eye. And the space-time frame itself is known only in its abstract mathematical properties; there is no reason to suppose it similar in intrinsic character to the spatial and temporal relations of our perceptions as known in experience. There does not seem any possible way of overcoming this ignorance, since the very nature of physical reasoning allows only the most abstract inferences, and only the most abstract properties of our perceptions can be regarded as having objective validity. Whether any other science than physics can tell us more, does not fall within the scope of the present article.

Meanwhile, it is a curious fact that this meagre kind of knowledge is sufficient for the *practical* uses of physics. From a practical point of view, the physical world only matters in so far as it affects us, and the intrinsic nature of what goes on in our absence is irrelevant, provided we can predict the effects upon ourselves. This we can do, just as a person can use a telephone without understanding electricity. Only the most abstract knowledge is required for practical manipulation of matter. But there is a grave danger when this habit of manipulation based upon mathematical laws is carried over into our dealings with human beings, since they, unlike the telephone wire, are capable of happiness and misery, desire and aversion. It would therefore be unfortunate if the habits of mind which are appropriate and right in dealing with material mechanisms were allowed to dominate the administrator's attempts at social constructiveness.

RELEASE, in law, the term applied to the discharge of some obligation, by which it is extinguished (*see* DEBT), and to the

conveyance of an estate or interest in real or personal property to one who has already some estate or interest therein. For the special form of conveyancing known as "lease and release," *see* LEASE.

RELICS, the name given in the Church to, (1) the bodies of the saints, or portions of them, (2) such objects as the saints made use of during their lives, or as were used at their martyrdom (Lat., *reliquiae*, the equivalent of the English "remains" in the sense of a dead body). These objects are held by the Church in religious veneration, and by their means it hopes to obtain divine grace and miraculous benefits (*Conc. Trid.* sess. 24).

These ideas had taken shape, in all essentials, during the early days of the Church, underwent further development in the middle ages, and were maintained by the Roman Church in the face of the opposition of the Reformers, while all the Protestant Churches rejected them.

The origins of the veneration of relics lie in the anxiety for the preservation of the bodies of the martyrs. The church at Smyrna at the death of their bishop Polycarp (155) collected and buried the remains of the martyr in order duly to celebrate the anniversary of the martyrdom at the place of burial.

The custom of which we have here for the first time an account had become universal by the 3rd century. In all parts the Christians assembled on the anniversary of the martyrs' death at their graves, to celebrate the Agape and the Eucharist at this spot. It was a favourite custom to bury the dead near the graves of the martyrs; and it was the highest wish of many to "rest with the saints." It was the body lying in the tomb which was venerated (*see* Euseb. *Hist. eccl.* vii. 11, 24; viii. 6, 7).

But these customs soon underwent a further development. About the end of the 3rd and the beginning of the 4th century it became customary for the bodies of the martyrs not to be buried, but preserved for the purpose of veneration. Already individual Christians began to possess themselves of portions of the bodies of martyrs, and to carry them about with them. Both these practices met with criticism and opposition, especially from the leading men of the Church. According to the testimony of Athanasius of Alexandria, the hermit Anthony decided that it should be held to be unlawful and impious to leave the bodies of the martyrs unburied (*Vita Ant.* 90). In Carthage the archdeacon and later the bishop Caecilianus severely blamed a certain Lucilla for carrying about with her a relic which she used to kiss before receiving the Eucharist (Optatus, *De schism. Donat.* i. 16). The compiler of the *Acta S. Fructuosi*, a Spanish ecclesiastic, represents the martyred bishop as himself requesting the burial of his relics. But energetic as the opposition was, it was unsuccessful, and died out. For in the meantime opinion as to the efficacy of relics had undergone a transformation, parallel with the growth of the theory, which soon predominated in the Church, that material instruments are the vehicles of divine grace. When the Christians of Smyrna decided that the bones of the martyrs were of more worth than gold or gems, and when Origen (*Exh. ad mart.* 50) spoke of the precious blood of the martyrs, they were thinking of the act of faith which the martyrs had accomplished by the sacrifice of their life. Now, on the other hand, the relic came to be looked upon as in itself a thing of value as the channel of miraculous divine powers. These ideas are set forth by Cyril of Jerusalem. He taught that a certain power dwelt in the body of the saint, even when the soul had departed from it; just as it was the instrument of the soul during life, so the power passed permanently into it (*Cat.* xviii. 16). This was coming very near to a belief that objects which the saints had used during their life had also a share in their miraculous powers. And this conclusion Cyril had already come to (*loc. cit.*).

We can see how early this estimate of relics became general from the fact that the former hesitation as to whether they should be venerated as sacred died out during the 4th century. The Fathers of the Greek Church especially were united in recommending the veneration of relics. All the great theologians of the 4th and 5th centuries may be quoted as evidence of this: Eusebius of Caesarea (*Praep. Ev.* xiii. 11), Gregory of Nazianzus (*Orat. in Cypr.* 17), Gregory of Nyssa (*Orat. de. S. Theod. Mart.*), Basil of Caesarea (*Ep.* ii. 197), Chrysostom (*Laud. Drosidis*), Theodoret of Cyrus (*Inps.* 67, 11), etc. John of Damascus, the great exponent of dogma in the 8th century, gave expression to the result of a uniform development which had been going on for centuries when he taught that Christ offers the relics to Christians as means of salvation.

Such was the theory; and the practice was in harmony with it. Throughout the whole of the Eastern Church the veneration of relics prevailed. Nobody hesitated to divide up the bodies of the saints in order to afford as many portions of them as possible. They were shared among the inhabitants of cities and villages, Theodoret tells us, and cherished by everybody as healers and physicians for both body and soul (*Decur. Graec. aff.* 8). The transition from the true relic to the hallowed object was especially common. Jerusalem, as early as the time of Eusebius, rejoiced in the possession of the episcopal chair of James the Just (*Hist. eccl.* vii. 19); and as late as the 4th century was discovered the most important of the relics of Christ, the cross which was alleged to have been His. Cyril of Jerusalem already remarks that the whole world was filled with portions of the wood of the cross (*Cat.* iv. 10).

The development which the veneration of relics underwent in the West did not differ essentially from that in the East. The only doubt which was felt was as to whether the bodies of the saints should be divided, and removed from their original resting-place. Both practices were forbidden by law under the emperor Theodosius I. (*Cod. Theodos.* ix. 17, 7), and the division of the bodies of martyrs into pieces was prohibited for centuries. Even Pope Gregory I., in a letter to the empress Constantia, disapproved it (*Ep.* iv. 30). Ambrose of Milan, by the discovery of the relics of Protasius and Gervasius (cf. *Ep.* 22 and Augustine, *Confess.* ix. 7), started in the West the long series of discoveries and translations of hitherto unknown relics. His example was followed, to name only the best known instances, by Bishop Theodore of Octodurum (now Martigny in the canton of Vaud), who discovered the relics of the Theban legion alleged to have been destroyed by the emperor Maximian on account of its belief in the Christian faith (see *Passio Acaun. Mart.* 16), and by Clematius, a citizen of Cologne, to whom the virgin martyrs of this city revealed themselves (Kraus, *Inschriften der Rheinlande,* No. 294), afterwards to be known as St. Ursula and her eleven thousand virgins.

The West was much poorer in relics than the East. Rome, it is true, possessed in the bodies of Peter and Paul a treasure the virtue of which outshone all the sacred treasures of the East. But many other places were entirely wanting in relics. By the discoveries which we have mentioned their number was notably increased. But the longing for these pledges of the divine assistance was insatiable. In order to satisfy it relics were made by placing pieces of cloth on the graves of the saints, which were afterwards taken by the pilgrims to their homes and venerated. The same purpose was served by oil taken from the lamps burning at the graves, flowers from the altars, water from some holy well, pieces of the garments of saints, earth from Jerusalem, and especially keys which had been laid on the grave of St. Peter at Rome. All these things were not looked upon as mementos, but the conviction prevailed that they were endowed with a miraculous power, which had passed into them through contact with that which was originally sacred (*cf.* Greg. Tur. *De Glor. Mart.* i. 25; Greg. I. *Ep.* iv. 29, No. 30). A dishonest means of satisfying the craving for relics was that of forging them, and how common this became can be gathered from the many complaints about spurious relics (Sulp. Sev. *Vita Mart.* 8; Aug. *De op. mon.* 28; Greg. I. *Ep.* iv. 30, etc.).

But in the long run these substitutes for relics did not satisfy the Christians of the West, and, following the example of the Eastern Church, they took to dividing the bodies of the saints. Mediaeval relics in the West also were mostly portions of the bodies of saints or of things which they had used during their lives. The veneration of relics also received a strong impulse from the fact that the Church required that a relic should be deposited

in every altar. Among the first of those whom we know to have attached importance to the placing of relics in churches is Ambrose of Milan (*Ep.* 22), and the 7th general council of Nicaea (787) forbade the consecration of churches in which relics were not present, under pain of excommunication. This has remained part of the law of the Roman Catholic Church.

The most famous relics discovered during the middle ages were those of the apostle James at St. Jago de Compostella in Spain (*see* PILGRIMAGE), the bodies of the three kings, which were brought from Milan to Cologne in 1164 by the emperor Frederick I. (*Chron. reg. Colon.* for the year 1164), the so-called *sudarium* of St. Veronica, which from the 12th century onwards was preserved in the Capella Santa Maria ad praesepe of St. Peter's in Rome (*see* Dobschütz, *Christusbilder*, p. 218 *seq.*), and the seamless robe of Christ, the possession of which lent renown to the cathedral of Trier since the beginning of the 12th century (*Gesta Trevir., Mon. Germ. Scr.* viii. p. 152).

The number of relics increased to a fabulous extent during the middle ages. There were churches which possessed hundreds, even thousands, of relics. In the cathedral of Eichstätt were to be found, as early as 1071, 683 relics (Gundech, *Lib. pont. Eist., Mon. Germ. Scr.* vii. p. 246 *seq.*); the monastery of Hirschau had 222 in the year 1091 (*De cons. mai. mon., Mon. Germ. Scr.* xiv. p. 261); the monastery of Stedernburg 515 in the year 1166 (*Ann. Sted. Scr.* xvi. p. 212 *seq.*). But these figures are trifling compared with those at the end of the middle ages. In the year 1520 could be counted 19,013 in the Schlosskirche at Wittenberg, and 21,483 in the Schlosskirche at Halle in 1521 (Köstlin, *Friedrich der W., und die Schlosskirche zu Wittenberg*, p. 58 *seq.*; Redlich, *Cardinal Albrecht und das Neue Stift zu Halle*, p. 260). There were also collections on the same scale belonging to individuals; a patrician of Nuremberg named Muffel had possession of 308 relics (*Chroniken der deutschen Städte*, xi. p. 745).

It is curious that while the popular craving for relics had passed all bounds, mediaeval theology was very cautious in its declarations on the subject of the veneration of relics. Thomas Aquinas based his justification of them on the idea of reverent commemoration; since we venerate the saints, we must also show reverence for their relics, for whoever loves another does honour to that which remains of him after death. On this account it is our duty, in memory of the saints, to pay due honour to their relics and especially to their bodies, which were the temples and dwellings of the Holy Ghost in which He dwelt and worked, and which in the resurrection are to be made like to the body of Christ; and likewise because God honours them, in that He works wonders in their presence (*Summa theol.* iii. qu. 25, art. 6). The great scholastic philosopher abandoned the theory that the relics in themselves are vessels and instruments of the divine grace and miraculous power. But these ideas were revived, on the other hand, by the Catholicism of the counter-Reformation, which again taught and teaches that God grants many benefits to mankind through the sacred bodies of the martyrs (*Conc. Trid.* sess. xxv.). The doctrine has adapted itself to the popular belief.

(A. HK.)

RELIEF, in sculpture a term signifying ornament, a figure or figures raised from the ground of a flat surface, of which the sculptured portion forms an inherent part of the body of the whole. The design may be in high relief—"alto-relievo" (*q.v.*), or low relief—"bas-relief" or "basso-relievo" (*q.v.*). The Egyptians merely sunk the outlines and barely suggested the modelling of the figures, which never projected beyond the face of the surrounding ground. The Persians, the Etruscans and the Greeks carried on the art to the highest perfection, alike in sculpture and architectural ornament, and they applied it to gem sculpture, as in the case of "cameo" (*q.v.*). Similarly, the inverse treatment of relief—that is, sunk *below* the surface, in order that when used for seals a true relief is obtained—was early brought to great completeness; this form of engraving is called "intaglio" (*q.v.*). The degree of projection in relief, broadly speaking, has varied greatly with the periods of art. Thus, in Byzantine and Romanesque art the relief was low. In Gothic it increased with the increased desire to render several planes one behind the other. With the Renaissance it became still more accentuated. Very full in Louis XIV. and Louis XV. styles, in Louis XVI. it is considerably reduced.

The term "relief" is also used as follows: it was one of the feudal incidents between lord and vassal, and consisted of a payment to the lord in kind or money made by the heir on the death of the ancestor for the privilege of succession, for, fiefs not being hereditary, the estate had lapsed to the lord. The word is also generally used, in law, for any exemption granted by a court from the strict legal consequences of an act. And also for the assistance given to the indigent poor by the Poor Law authorities.

RELIGION AND THEOLOGY, ARTICLES ON. For the purpose of enumerating the main articles in this section, a division will be made into (1) Christian, and (2) Non-Christian.

(1) CHRISTIAN

The number of articles on the different aspects of Christian doctrine, faith and Church is so great that nothing beyond a casual selection of titles can be made here. Anything approaching a complete guide to the separate religious divisions would be a lengthy index of titles of differing merit. To begin with, all the prophets of the Old Testament, all the disciples of the New Testament, and all the books of the Bible have separate articles under their own headings. Special terms occurring in the Scriptures, such as ALPHA AND OMEGA; ARMAGEDDON; APOSTLE; ANGEL, etc., have articles to themselves, where their meaning and connection with other passages in Holy Writ are given in some detail. The article BIBLE is divided, for convenience of reference, into sections and sub-sections, with appropriate subheads and sideheads to mark out the main points of interest. CONCORDANCE is exhaustively treated, and the article JESUS CHRIST deals with the life of the Founder of Christianity and all His activities and influences. JOSEPH (husband of Mary) and MARY (the Mother of Jesus), are important articles, and those such as APOCALYPSE and PASTORAL EPISTLES are deserving of attention. VULGATE; ATHEISM; DEISM; IMMORTALITY; MIRACLE; MYSTICISM; ESCHATOLOGY; APOLOGETICS; DOGMA; DOGMATIC THEOLOGY; ABSOLUTION; ANTICHRIST; APOSTASY; ATONEMENT; BAPTISM; BENEDICTION; CATECHISM; CATHOLIC; CHURCH; CONFESSION; CONFIRMATION; CREEDS; EXCOMMUNICATION; EXTREME UNCTION; FASTING; GRACE; MARTYR; PREACHING; RELICS; SACRAMENT; SECT; SIN; SYNOD and WORSHIP, are all important articles worthy of special attention. The different sects and divisions of Christian practice and worship are treated under their own headings.

CHURCH HISTORY is a long article suitably sub-divided for convenience of reference. The different councils (*e.g.*, COUNCIL OF BASEL, etc.) are treated in separate articles apart from the main article COUNCIL. The synods, too, have special articles under the names they usually bear, as is also the case with the different courts. The famous heresies are also treated under their separate names. There is also a large article PAPACY.

The chief saints of the Church Calendar are noted and details are given under their respective names. The popes have biographies, and are also treated in connection with their special work in separate articles where there is historical mention of their times. There is a sub-section of religion entitled *Christian Documents*, and it has been found more satisfactory to treat these separately, under their own headings, rather than in a general group. The reader should, therefore, refer to APOSTOLICAL CONSTITUTIONS; APOSTOLIC CANONS; DIDACHE, THE, etc., for the documents required.

There are comprehensive articles on the religious orders. (*See* for example, AMBROSIANS; BENEDICTINES; CAPUCHINS, etc.) In addition to the main article ROMAN CATHOLIC CHURCH, all important sub-divisions of this aspect of Christian worship have articles under their own headings, *e.g.*, IMMACULATE CONCEPTION; INDULGENCE; PENANCE, etc. All the main Eastern Churches have articles devoted specially to them. All relationships of the Church of England and the modern Continental Churches, their special forms of worship and attitude to problems of belief and practice, are treated under their own headings. Ecclesiastical offices are

treated under separate headings, *e.g.*, ABBESS; ACOLYTE; ARCHBISHOP; ARCHDEACON, etc. The ecclesiastical seasons have all their own headings, and this is also the case with Ecclesiology and its sub-divisions. Bible and Biblical Criticism is a section which contains important articles on the prophets and books of the Old Testament, and the Apostles and books of the New.

2. NON-CHRISTIAN

In this section appear such major articles as BABYLONIAN AND ASSYRIAN RELIGION; GREEK RELIGION; ROMAN RELIGION; HINDUISM; ANCESTOR WORSHIP; ZOROASTER (for Zoroastrianism); ASCETICISM, etc. Apart from the main articles on Greek and Roman Religion, there are numerous short articles on the gods and goddesses of the ancient classical world. Such articles as ANIMISM; ANTHROPOMORPHISM; DEMONOLOGY; DIVINATION; EXORCISM; FETISHISM; FUNERAL RITES; IDOLATRY; IMAGE WORSHIP; LYCANTHROPY; MYTHOLOGY; NECROMANCY; PRIEST; RITUAL and WITCHCRAFT are the main supports of the non-Christian religious programme.

In addition to these there are numerous accounts, each under its own heading, of the gods and spirits of Brahmanism, Buddhism, etc., and the early faiths of Scandinavia, Europe, and the two divisions of America.

RELIGION. The treatment of this subject will fall into two distinct sections, *A. Primitive Religion* and *B. The Higher Religions.*

A. PRIMITIVE RELIGION

I. Definition of Primitive Religion.—Amongst the numberless definitions of religion that have been suggested, those that have been most frequently adopted for working purposes by anthropologists are Tylor's and Frazer's. Sir E. B. Tylor in *Primitive Culture* (1), i. 424, proposes as a "minimum definition" of religion "the belief in spiritual beings." Objections to this definition on the score of incompleteness are, firstly, that, besides belief, practice must be reckoned with (since, as W. Robertson Smith has made clear in his *Lectures on the Religion of the Semites*, 18 *sqq.*, ritual is in fact primary for primitive religion, whilst dogma and myth are secondary); secondly, that the outlook of such belief and practice is not exclusively towards the spiritual, unless this term be widened until it mean next to nothing, but is likewise towards the quasi-material, as will be shown presently. The merit of this definition, on the other hand, lies in its bilateral form, which calls attention to the need of characterizing both the religious attitude and the religious object to which the former has reference. The same form appears in Sir J. G. Frazer's definition in *The Golden Bough* (3rd ed.), i. 222. He understands by religion "a propitiation or conciliation of powers superior to man which are believed to direct and control the course of nature and of human life." He goes on to explain that by "powers" he means "conscious or personal agents." It is also to be noted that he is here definitely opposing religion to magic, which he holds to be based on the (implicit) assumption "that the course of nature is determined, not by the passions or caprice of personal beings, but by the operation of immutable laws acting mechanically." His definition improves on Tylor's in so far as it makes worship integral to the religious attitude. By regarding the object of religion as necessarily personal, however, he is led to exclude much that the primitive man undoubtedly treats with awe and respect as exerting a mystic effect on his life. Further, in maintaining that the powers recognized by religion are always superior to man, he leaves unclassed a host of practices that display a bargaining, or even a hectoring, spirit on the part of those addressing them (*see* PRAYER). Threatening or beating a fetish cannot be brought under the head of magic, even if we adopt Frazer's principle (*op. cit.* i. 225) that to constrain or coerce a personal being is to treat him as an inanimate agent; for such a principle is quite inapplicable to cases of mere terrorism, whilst it may be doubted if it even renders the sense of the magician's typical notion of his mode of operation, viz., as the bringing to bear of a greater *mana* or psychic influence (*see* below) on what has less, and must therefore do as it is bidden. Such definitions, then, are to be accepted, if at all, as definitions of type, selective designations of leading but not strictly universal features. An encyclopaedic account, however, should rest rather on an exterior definition which can serve as it were to pigeon-hole the whole mass of significant facts. Such an exterior definition is suggested by E. Crawley in *The Tree of Life*, 209, where he points out that "neither the Greek nor the Latin language has any comprehensive term for religion, except in the one ἱερά and in the other *sacra*, words which are equivalent to 'sacred.' No other term covers the whole of religious phenomena, and a survey of the complex details of various worships results in showing that no other conception will comprise the whole body of religious facts." It may be added that we have here no generalization imported from a higher level of culture, but an idea or blend of ideas familiar to primitive thought. An important consequence of thus giving the study of primitive religion the wide scope of a comparative hierology is that magic is no longer divorced from religion, since the sacred will now be found to be coextensive with the magico-religious, that largely undifferentiated plasm out of which religion and magic slowly take separate shapes as society comes more and more to contrast legitimate with illicit modes of dealing with the sacred. We may define, then, the religious object as the sacred, and the corresponding religious attitude as consisting in such manifestation of feeling, thought and action in regard to the sacred as is held to conduce to the welfare of the community or to that of individuals considered as members of the community.

II. Aspects of the Nature of the Sacred.—To exhibit the general character of the sacred as it exists for primitive religion it is simplest to take stock of various aspects recognized by primitive thought as expressed in language. If some, and not the least essential, of these aspects are quasi-negative, it must be remembered that negations—witness the Unseen, the Unknown, the Infinite of a more advanced theology—are well adapted to supply that mystery on which the religious consciousness feeds with the slight basis of conceptual support it needs. (1) *The sacred as the forbidden.* The primitive notion that perhaps comes nearest to our "sacred," whilst it immediately underlies the meanings of the Latin *sacer* and *sanctus*, is that of a *taboo*, a Polynesian term for which equivalents can be quoted from most savage vocabularies. The root idea seems to be that something is marked off as to be shunned, with the added hint of a mystic sanction or penalty enforcing the avoidance. Two derivative senses of a more positive import call for special notice. On the one hand, since that which is tabooed is held to punish the taboo-breaker by a sort of mystic infection, taboo comes to stand for uncleanness and sin. On the other hand, since the isolation of the sacred, even when originally conceived in the interest of the profane, may be interpreted as self-protection on the part of the sacred as against defiling contact, taboo takes on the connotation of ascetic virtue, purity, devotion, dignity and blessedness. Primary and secondary senses of the term between them cover so much ground that it is not surprising to find taboo used in Polynesia as a name for the whole system of religion, founded as it largely is on prohibitions and abstinences. (2) *The sacred as the mysterious.* Another quasi-negative notion of more restricted distribution is that of the mysterious or strange, as we have it expressed, for example, in the Siouan *wakan*, though possibly this is a derivative meaning. Meanwhile, it is certain that what is strange, new or portentous is regularly treated by all savages as sacred. (3) *The sacred as the secret.* The literal sense of the term *churinga*, applied by the Central Australians to their sacred objects, and likewise used more abstractly to denote mystic power, as when a man is said to be "full of *churinga*," is "secret," and is symptomatic of the esotericism that is a striking mark of Australian, and indeed of all primitive, religion, with its insistence on initiation, its exclusion of women, and its strictly enforced reticence concerning traditional lore and proceedings. (4) *The sacred as the potent.* Passing on to positive conceptions of the sacred, perhaps the most fundamental is that which identifies the efficacy of sacredness with such mystic or magical power as is signified by the *mana* of the Pacific or *orenda* of the Hurons, terms for which analogies are forthcoming on all

sides. Of *mana* R. H. Codrington in *The Melanesians*, 119 *n.*, writes: "It essentially belongs to personal beings to originate it, though it may act through the medium of water, or a stone or a bone. All Melanesian religion consists . . . in getting this *mana* for oneself, or getting it used for one's benefit." E. Tregear's *Maori-Polynesian Comparative Dictionary* shows how the word and its derivatives are used to express thought, memory, emotion, desire, will—in short, psychic energy of all kinds. It also stands for the vehicle of the magician's energy—the spell; which would seem likewise to be a meaning, perhaps the root-meaning, of *orenda* (*cf.* J. N. B. Hewitt, *American Anthropologist*, N.S., iv. 40). Whereas everything, perhaps, has some share of indwelling potency, whatever is sacred manifests this potency in an extraordinary degree, as typically the wonder-working leader of society, whose *mana* consists in his cunning and luck together. Altogether, in *mana* we have what is *par excellence* the primitive religious idea in its positive aspect, taboo representing its negative side, since whatever has *mana* is taboo, and whatever is taboo has *mana*. (5) *The sacred as the animate.* The term "animism," which embodies Tylor's classical theory of primitive religion, is unfortunately somewhat ambiguous. If we take it strictly to mean the belief in ghosts or spirits having the "vaporous materiality" proper to the objects of dream or hallucination, it is certain that the agency of such phantasms is not the sole cause to which all mystic happenings are referred (though ghosts and spirits are everywhere believed in, and appear to be endowed with greater predominance as religious synthesis advances amongst primitive peoples). Thus there is good evidence to show that many of the early gods, notably those that are held to be especially well disposed to man, are conceived rather in the shape of magnified non-natural men dwelling somewhere apart, such as the Mungan-ngaur of the Kurnai of S.E. Australia (*cf.* A. Lang, *The Making of Religion*, x. *seq.*). Such anthropomorphism is with difficulty reduced to the Tylorian animism. The term, however, will have to be used still more vaguely, if it is to cover all attribution of personality, will or vitality. This can be more simply brought under the notion of *mana*. Meanwhile, since quasi-mechanical means are freely resorted to in dealing with the sacred, as when a Maori chief snuffs up the sanctity his fingers have acquired by touching his own sacred head that he may restore the virtue to the part whence it was taken (R. Taylor, *Te Ika a Maui*, 165), or when uncleanness is removed as if it were a physical secretion by washing, wiping and so forth, it is hard to say whether what we should now call a "material" nature is not ascribed to the sacred, more especially when its transmissibility after the manner of a contagion is the trait that holds the attention. It is possible, however, that the savage always distinguishes in a dim way between the material medium and the indwelling principle of vital energy, examples of a pure fetishism, in the sense of the cult of the purely material, recognized as such, being hard to find. (6) *The sacred as the ancient.* The prominence of the notion of the *Alcheringa* "dreamtime," or sacred past, in Central Australian religion illustrates the essential connection perceived by the savage to lie between the sacred and the traditional. Ritualistic conservatism may be instanced as a practical outcome of this feeling. Another development is ancestor-worship, the organized cult of ancestors marking, however, a certain stage of advance beyond the very primitive, though the dead are always sacred and have *mana* which the living may exploit for their own advantage.

III. The Activity of the Sacred.—The foregoing views of the sacred, though starting from distinct conceptions, converge in a single complex notion, as may be seen from the many-sided sense borne by such a term as *wakan*, which may stand not only for "mystery," but also for "power, sacred, ancient, grandeur, animate, immortal" (W. J. McGee, *15th Report of U. S. Bureau of Ethnology*, 182). The reason for this convergence is that, whereas there is found great difficulty in characterizing the elusive nature of the sacred, its mode of manifesting itself is recognized to be much the same in all its phases. Uniform characteristics are the fecundity, ambiguity, relativity and transmissibility of its activity. (1) *Fecundity.* The mystic potency of the sacred is no fixed quantity, but is big with possibilities of all sorts. The same sacred person, object, act, will suffice for a variety of purposes. Even where a piece of sympathetic magic appears to promise definite results, or when a departmental god is recognized, there would seem to be room left for a more or less indefinite expectancy. It must be remembered that the meaning of a rite is for the most part obscure to the participants, being overlaid by its traditional character, which but guarantees a general efficacy. "Blessings come, evils go," may be said to be the magico-religious formula implicit in all socially approved dealings with the sacred, however specialized in semblance. (2) *Ambiguity.* Mystic potency, however, because of the very indefiniteness of its action, is a two-edged sword. The sacred is not to be approached lightly. It will heal or blast, according as it is handled with or without due circumspection. That which is taboo, for instance, the person of the king, or woman's blood, is poison or medicine according as it is manipulated, being inherently just a potentiality for wonder-working in any direction. Not but what primitive thought shows a tendency to mark off a certain kind of mystic power as wholly bad by a special name, *e.g.*, the *arungquilta* of Central Australia; and here, we may note, we come nearest to a conception of magic as something other than religion, the trafficker in *arungquilta* being socially suspect, nay, liable to persecution, and even death (as amongst the Arunta tribe, *see* Spencer and Gillen, *The Arunta*, ii. 414 *n.*), at the hands of his fellows. On the other hand, wholly beneficent powers seem hardly to be recognized, unless we find them in beings such as Mungan-ngaur ("father-our"), who derive an ethical character from their association with the initiation ceremonies and the moral instruction given thereat (*cf.* Lang, *l.c.*). (3) *Relativity.* So far we have tended to represent the activity of the sacred as that of a universal force, somewhat in the style of our "electricity" or "mind." It remains to add that this activity manifests itself at numberless independent centres. These differ amongst themselves in the degree of their energy. One spell is stronger than another, one taboo more inviolable than another. W. H. R. Rivers (*The Todas*, 448) gives an interesting analysis of the grades of sanctity apparent in Toda religion. The gods of the hill-tops come first. The sacred buffaloes, their milk, their bells, the dairies and their vessels are on a lower plane; whilst we may note that there are several grades amongst the dairies, increase of sanctity going with elaboration of dairy ritual (*cf. ibid.* 232). Still lower is the dairyman, who is in no way divine, yet has sanctity as one who maintains a condition of ceremonial purity. (4) *Transmissibility.* If, however, this activity originates at certain centres, it tends to spread therefrom in all directions. F. B. Jevons (in *An Introduction to the History of Religion*, vii.) distinguishes between "things taboo," which have the mystic contagion inherent in them, and "things tabooed," to which the taboo-infection has been transmitted. In the former class he places supernatural beings (including men with *mana* as well as ghosts and spirits), blood, new-born children with their mothers, and corpses; which list might be considerably extended, for instance, by the inclusion of natural portents, and animals and plants such as are strikingly odd, dangerous or useful. Any one of these can pass on its sacred quality to other persons and objects (as a corpse defiles the mourner and his clothes), nay to actions, places and times as well (as a corpse will likewise cause work to be tabooed, ground to be set apart, a holy season to be observed). Such transmissibility is commonly explained by the association of ideas, that becoming sacred which as it were reminds one of the sacred; though it is important to add, firstly, that such association takes place under the influence of a selective interest generated by strong religious feeling, and, secondly, that this interest is primarily a collective product, being governed by a social tradition which causes certain possibilities of ideal combination alone to be realized, whilst it is the chief guarantee of the objectivity of what they suggest.

IV. The Exploitation of the Sacred. A. Methods.—It is hard to find terms general enough to cover dealings with the sacred that range from the manipulation of an almost inanimate type of power to intercourse modelled on that between man and man. Primitive religion, however, resorts to either way of ap-

proach so indifferently as to prove that there is little or no awareness of an inconsistency of attitude. The radical contrast between mechanical and spiritual religion, though fundamental for modern theology, is alien to the primitive point of view, and is therefore inappropriate to the purposes of anthropological description. (1) *Acquisition.* Mystic power may be regarded as innate so far as skill, luck or queerness are signs and conditions of its presence. On the whole, however, savage society tends to regard it as something acquired, the product of acts and abstinences having a traditional character for imparting magico-religious virtue. An external symbol in the shape of a ceremony or cult-object is of great assistance to the dim eye of primitive faith. Again, the savage universe is no preserve of man, but is an open field wherein human and non-human activities of all sorts compete on more or less equal terms, yet so that a certain measure of predominance may be secured by a judicious combination of forces. (2) *Concentration.* Hence the magico-religious society or individual practitioner piles ceremony on ceremony, name of power on name of power, relic on relic, to consolidate the forces within reach and assume direction thereof. The transmissibility of the sacred ensures the fusion of powers drawn from all sources, however disparate. (3) *Induction.* It is necessary, however, as it were, to bring this force to a head. This would appear to be the essential significance of sacrifice, where a number of sacred operations and instruments are made to discharge their efficacy into the victim as into a vat, so that a blessing-yielding, evil-neutralizing force of highest attainable potency is obtained (*see* H. Hubert and M. Mauss, "Essai sur la nature et la fonction du sacrifice" in *L'Année sociologique,* ii.). (4) *Renovation.* An important *motif* in magico-religious ritual, which may not have been without effect on the development of sacrifice, is, as Frazer's main thesis in *The Golden Bough* asserts, the imparting of reproductive energy to animals, plants and man himself, its cessation being suggested by such phenomena as old age and the fall of the year. To concentrate, induce and renovate are, however, but aspects of one process of acquisition by the transfusion of a transmissible energy. (5) *Demission.* Hubert and Mauss show in their penetrating analysis of sacrifice that after the rite has been brought to its culminating point there follows as a pendant a ceremony of re-entry into ordinary life, the idea of which is preserved in the Christian formula *Ite, missa est.* (6) *Insulation.* Such deposition of sacredness is but an aspect of the wider method that causes a ring-fence to be erected round the sacred to ward off casual trespassers at once in their own interest and to prevent contamination. We see here a natural outcome of religious awe supported by the spirit of esotericism, and by a sense of the need for an expert handling of that which is so potent for good or ill. (7) *Direction.* This last consideration brings to notice the fact that throughout magico-religious practice of all kinds the human operator retains a certain control over the issue. In the numberless transitions that, whilst connecting, separate the spell and the prayer we observe as the accompaniment of every mood from extreme imperiousness to extreme humility an abiding will and desire to help the action out. Even "Thy will be done" preserves the echo of a direction, and, needless to say, this is hardly a form of primitive address. At the bottom is the vague feeling that it is man's own self-directed mysterious energy that is at work, however much it needs to be reinforced from without. Meanwhile, tradition strictly prescribes the ways and means of such reinforcement, so that religion becomes largely a matter of sacred lore; and the expert director of rites, who is likewise usually at this stage the leader of society, comes more and more to be needed as an intermediary between the lay portion of the community and the sacred powers.

V. Results.—Hitherto our account of primitive religion has had to move on somewhat abstract lines. His religion is, however, anything but an abstraction to the savage, and stands rather for the whole of his concrete life so far as it is penetrated by a spirit of earnest endeavour. The end and result of primitive religion is, in a word, the consecration of life, the stimulation of the will to live and to do. This bracing of the vital feeling takes place by means of imaginative appeal to the great forces man perceives stirring within him and about him, such appeal proving effective doubtless by reason of the psychological law that to conceive strongly is to imitate. Meanwhile, security against any clashing of conceptions to inhibit the tendency of the idea of an acquired "grace" to realize itself in action, is assured by the complete unanimity of public opinion, dominated as it is by an inveterate custom. To appreciate the consecrating effect of religion on primitive life we have only to look to the *churinga*-worship of the Central Australians (as described by Spencer and Gillen in *The Native Tribes of Central Australia,* [1] *The Northern Tribes of Central Australia* and *The Arunta*). Contact with these repositories of mystic influence "makes them glad" (*Nat. Tr.* 165); it likewise makes them "good," so that they are no longer greedy or selfish (*North. Tr.* 266); it endows them with second sight (*ibid.*); it gives them confidence and success in war (*Nat. Tr.* 135); in fact, there is no end to its "strengthening" effects (*ibid. n.*). Or, again, we may note the earnestness and solemnity that characterize all their sacred ceremonies. The inwardness of primitive religion is, however, non-existent for those who observe it as uninitiated strangers; whilst, again, it evaporates as soon as native custom breaks down under pressure of civilization, when only fragments of meaningless superstition survive: for which reason travesties of primitive religion abound.

It remains to consider shortly the consecration of life in relation to particular categories and departments. (1) *Education.* Almost every tribe has its initiation ceremonies, and in many tribes adult life may almost be described as a continuous initiation. The object of these rites is primarily to impart mystic virtue to the novice, such virtue, in the eyes of the primitive man, being always something more than social usefulness, amounting as it does to a share in the tribal luck by means of association with all it holds sacred. Incidentally the candidate is trained to perform his duties as a tribesman, but religion presides over the course, demanding earnest endeavour of an impressionable age. (2) *Government.* Where society is most primitive it is most democratic, as in Australia, and magico-religious powers are possessed by the whole body of fully initiated males, age, however, conferring increase of sacred lore and consequently of authority; whilst even at this stage the experts tend to form an inner circle of rulers. The man with *mana* is bound to come to the top, both because his gifts give him a start and because his success is taken as a sign that he has the gift. A decisive "moment" in the evolution of chiefship is the recognition of hereditary *mana,* bound up as this is with the handing on of ceremonies and cult-objects. Invested, as society grows more complex, with a sanctity increasingly superior to that of the layman, the priest-king becomes the representative of the community as repository of its luck, whilst, as controller of all sacred forces that bear thereon, he is, as Frazer puts it, "dynamical centre of the universe" (*The Golden Bough* [3rd ed.], iii. 1). Only when the holy man's duty to preserve his holiness binds him hand and foot in a network of taboos does his temporal power tend to devolve on a deputy. (3) *Food-supply.* In accordance with the principle of Renovation (*see* above), the root-idea of the application of religion to economics is not the extorting of boons from an unwilling nature, but rather the stimulation of the sources of life, so that all beings alike may increase and multiply. (4) *Food-taking.* Meanwhile, the primitive meal is always more or less of a sacrament, and there are many food-taboos, the significance of which is, however, not so much that certain foods are unclean and poisonous as that they are of special virtue and must be partaken of solemnly and with circumspection. (5) *Kinship.* It is hard to say whether the unit of primitive society is the tribe or the group of kinsmen. Both are forms of union that are consolidated by means of religious usages. Thus in Australia the initiation ceremonies, concerned as they partly are with marriage, always an affair between the kin-groups, are tribal, whilst the totemic rites are the prime concern of the members of the totem clans. The significance of a common name and a common blood is immensely enhanced by its association with mystic rights and duties, and the pulse of brotherhood beats faster. (6) *The Family.* Side by side with the kin there is always found the domestic group, but the latter

institution develops fully only as the former weakens, so that the one comes largely to inherit the functions of the other, whilst the tribe too in its turn hands over certain interests. Thus in process of time birth-rites, marriage-rites, funeral-rites, not to mention subordinate ceremonies such as those of name-giving and food-taking, become domestic sacraments. (7) *Sex.* Woman, for certain physiological reasons, is always for primitive peoples hedged round with sanctity, whilst man does all he can to inspire awe of his powers in woman by keeping religion largely in his own hands. The result, so far as woman is concerned, is that, in company with those males who are endowed with sacredness in a more than ordinary degree, she tends as a sex to lose in freedom as much as she gains in respect. (8) *Personality.* Every one has his modicum of innate *mana*, or at least may develop it in himself by communicating with powers that can be brought into answering relation by the proper means. Nagualism, or the acquisition of a mystic guardian, is a widely distributed custom, the essence of which probably consists in the procuring of a personal name having potency. The exceptional man is recognized as having *mana* in a special degree, and a belief thus held at once by others and by himself is bound to stimulate his individuality. The primitive community is not so custom-bound that personality has no chance to make itself felt, and the leader of men possessed of an inner fund of inspiration is the wonder-worker who encourages all forms of social advance.

VI. Psychology of the Primitive Attitude Towards the Sacred.—We are on firmer ground when simply describing the phenomena of primitive religion than when seeking to account for these in terms of natural law—in whatever sense the conception of natural law be applicable to the facts of the mental life of man. One thing is certain, namely, that savages stand on virtually one footing with the civilized as regards the type of explanation appropriate to their beliefs and practices. We have no right to refer to "instincts" in the case of primitive man, any more at any rate than we have in our own case. A child of civilized parents brought up from the first amongst savages is a savage, neither more nor less. Though race may count for something in the matter of mental effectiveness—and at least it would seem to involve differences in weight of brain—it clearly counts for much less than does *milieu*, to wit, that social environment of ideas and institutions which depends so largely for its effectiveness on mechanical means of tradition, such as the art of writing. The outstanding feature of the mental life of savages known to psychologists as "primitive credulity" is doubtless chiefly due to sheer want of diversity of suggestiveness in their intellectual surroundings. Their notions stick fast because there are no competing notions to dislodge them. Society suffers a sort of perpetual obsession, and remains self-hypnotized as it were within a magic circle of traditional views. A rigid orthodoxy is sustained by means of purblind imitation assisted by no little persecution. Such changes as occur come about, not in consequence of a new direction taken by conscious policy, but rather in the way that fashions in dress alter amongst ourselves, by subconscious, hardly purposive drifting. The crowd rather than the individual is the thinking unit. A proof is the mysterious rapid extinction of savages the moment that their group-life is broken up; they are individually so many lost sheep, without self-reliance or initiative. And the thinking power of a crowd—that is, a mob, not a deliberative assembly—is of a very low order, emotion of a "panicky" type driving it hither and thither like a rudderless ship. However, as the students of mob-psychology have shown, every crowd tends to have its *meneur*, its mob-leader, the man who sets the cheering or starts the running-away. So too, then, with the primitive society. Grossly ignorant of all that falls outside "the daily round, the common task," they are full of panicky fears in regard to this unknown, and the primary attitude of society towards it is sheer avoidance, taboo. But the mysterious has another face. To the mob the mob-leader is mysterious in his power of bringing luck and salvation; to himself also he is a wonder, since he wills, and lo! things happen accordingly. He has *mana*, power, and by means of this *mana*, felt inwardly by himself, acknowledged by his fellows, he stems the social impulse to run away from a mystery. Not without nervous dread—witness the special taboo to which the leader of society is subject—he draws near and strives to constrain, conciliate or cajole the awful forces with which the life of the group is set about. He enters the Holy of Holies; the rest remain without, and are more than half afraid of their mediator. In short, from the standpoint of lay society, the manipulator of the sacred is himself sacred, and shares in all the associations of sacredness. An anthropomorphism which is specifically a "magomorphism" renders the sacred powers increasingly one with the governing element in society, and religion assumes an ethico-political character, whilst correspondingly authority and law are invested with a deeper meaning.

VII. The Abuse of the Sacred.—Lest our picture of primitive religion appear too brightly coloured, a word must be said on the perversions to which the exploitation of the sacred is liable. Envy, malice and uncharitableness are found in primitive society, as elsewhere, and on their behalf the mystic forces are not infrequently unloosed by those who know how to do so. To use the sacred to the detriment of the community, as does, for instance, the expert who casts a spell, or utters a prayer, to his neighbour's hurt, is what primitive society understands by magic (*cf. arungquilta*, above), and anthropology has no business to attach any other meaning to the word if it undertakes to interpret the primitive point of view. On the other hand, if those in authority perpetrate in the name of what their society holds sacred, and therefore with its full approval, acts that to the modern mind are cruel, silly or revolting, it is bad science and bad ethics to speak of vice and degradation, unless it can be shown that the community in which these things occur is thereby brought nearer to elimination in the struggle for existence. As a matter of fact, the earlier and more democratic types of primitive society, uncontaminated by our civilization, do not present many features to which the modern conscience can take exception, but display rather the edifying spectacle of religious brotherhoods encouraging themselves by mystical communion to common effort. With the evolution of rank, however, and the concentration of magico-religious power in the hands of certain orders, there is less solidarity and more individualism, or at all events more opportunity for sectional interests to be pursued at other than critical times; whereupon fraud and violence are apt to infect religion. Indeed, as the history of the higher religions shows, religion tends in the end to break away from secular government with its aristocratic traditions, and to revert to the more democratic spirit of the primitive age, having by now obtained a clearer consciousness of its purpose, yet nevertheless clinging to the inveterate forms of human ritual as still adequate to symbolize the consecration of life—the quickening of the will to face life earnestly.

BIBLIOGRAPHY.—The number of works dealing with primitive religion is endless. The English reader who is more or less new to the subject is recommended to begin with Sir E. B. Tylor, *Primitive Culture* (4th ed., Lond. 1903), and then to proceed to Sir J. G. Frazer, *The Golden Bough* (3rd ed., Lond. 1911–15), together with his other works *The Belief in Immortality* 1913; *Folk-Lore in the Old Testament*, 1919; *The Worship of Nature*, 1926. Only second in importance to the above are W. Robertson Smith, *Lectures on the Religion of the Semites* (3rd ed. with Introd. and additional notes by Dr. S. A. Cook, Lond. 1927); A. Lang, *Myth, Ritual and Religion* (2nd ed., Lond. 1899), and *Magic and Religion* (Lond. 1902); E. S. Hartland, *The Legend of Perseus* (Lond. 1894–96); F. B. Jevons, *An Introduction to the History of Religion* (2nd ed., 1902); E. Crawley, *The Tree of Life* and *The Mystic Rose* (2nd ed. Lond. 1927). The two last-mentioned works perhaps most nearly represent the views taken in the text, which are also developed by the present writer in *The Threshold of Religion* (2nd ed., 1909) and *Psychology and Folk-Lore*, 1920. *See* also H. Hubert and M. Mauss, "Essai sur la nature et la fonction du sacrifice," *L'Année sociologique*, ii.; and "Esquisse d'une théorie générale de la magie," *ibid* vii.; E. Durkheim, *Les formes élémentaires et la vie religieuse*, Paris, 1912; L. Levy-Bruhl, *Les fonctions mentales dans les sociétes inférieures*, Paris, 1912; R. H. Lowie, *Primitive Religion*, 1925, E. Westermarck, *Ritual and Belief in Morocco*, 1926; R. Briffault, *The Mothers*, 1927.

Side by side with works of general theory, first-hand authorities should be freely used. To make a selection from these is not easy, but the following at least are very important: R. H. Codrington, *The Melanesians* (Oxford, 1891); W. B. Spencer and F. J. Gillen, *The*

Native Tribes of Central Australia (Lond. 1899); *The Northern Tribes of Central Australia* (Lond. 1904); *The Arunta* (Lond. 1927); A. W. Howitt, *The Native Tribes of South-Eastern Australia* (Lond. 1904); A. C. Haddon, *Reports of the Cambridge Anthropological Expedition to Torres Straits* (Cambridge, 1904, vol. v.); A. B. Ellis, *The Tshi-Speaking Peoples of the Gold Coast* (Lond. 1897); *The Ewe-Speaking Peoples of the Slave Coast* (Lond. 1890); *The Yoruba-Speaking Peoples of the Slave Coast* (Lond. 1894); Miss M. H. Kingsley, *Travels in West Africa* (Lond. 1898), and *West African Studies* (Lond. 1899); R. S. Rattray, *Ashanti* (1923); *Religion and Art in Ashanti* (1927); E. Westermarck, *Ritual and Belief in Morocco* (1926); A. C. Hollis, *The Masai* (1905); W. Crooke, *The North-West Provinces of India* (Lond. 1897); W. H. R. Rivers, *The Todas* (1906). An immense amount of valuable evidence is to be obtained in the *Reports of the Bureau of Ethnology*, Smithsonian Institution, Washington. *See* Nos. 2, 5, 6, 7, 8, 9, 11, 13, 14, 15, 16, 18, 19, 21, 22, 23, and specially J. O. Dorsey, *A Study of Siouan Cults*, in No. 11; A. C. Fletcher, *The Hako*, in No. 22; and M. C. Stevenson, *The Zuñi Indians*, in No. 23. Though dealing primarily with a more advanced culture, J. J. M. de Groot, *The Religious System of China* (1892–1901), will be found to throw much light on primitive ideas. Finally let it be repeated that there is offered here no more than an introductory course of standard authorities suitable for the English reader. (R. R. M.)

B. THE HIGHER RELIGIONS

No attempt can here be made to deal in detail with the Higher Religions. These are treated elsewhere under their respective headings. The different Higher Religions will only be considered in so far as they exhibit general principles. The main object of this section will be to show the lines on which the higher religious consciousness has developed, the broad features which it discloses, and the way in which it gives expression to human needs.

I. THE BASIS OF HIGHER RELIGION

Higher religions have developed on a pre-existing basis, in response to an impulse of the religious spirit seeking better self-expression. They have grown out of primitive religion, and all of them exhibit traces of their lineage. The survival of primitive traits in developed religion is a recurring phenomenon.

Evidently a higher religion can only emerge from a lower by a process of selection and development. Certain elements in early religion were intractable to development, while others were capable of it. To the former must be reckoned the strongly local character and particularist tendency of primitive religion. Spirits or powers attached to a definite spot, or embodied in a specific object, are not easily elevated or expanded. Sentiment is conservative, and the being reverenced is too much lacking in individual quality to be readily transformed into a personal god. On the other hand, though the feeling of the clan that its objects of worship belong to it resists absorption in a larger cult, the strong sense of affinity with divine powers is capable of being elevated to a higher religious relationship. The same holds of primitive rites of communion. So too primitive ideas of Tabu and Interdiction have naturally passed into conceptions of the sacred and not-sacred, the pure and the impure, ideas that play a great part in developed religion. Again the cult of the dead, passing into that of family ancestors (*see* ANCESTOR-WORSHIP) easily expands with the enlargement of society: it has contributed important elements to national religion as in the case of China and ancient Rome. There are then higher possibilities in primitive religion, but they can only come to fruition with the emergence of new needs and a wider outlook.

II. THE RISE AND GROWTH OF POLYTHEISM

Higher religions emerge after the tribal has been superseded by the national culture. The transition to the more developed stage was the outcome of social changes which were reflected in the growth of man's inner life. This enrichment of personal life carried with it the need of a revised idea of the objects of worship and of the religious relation. The old spiritism, with its multitude of indefinite powers and capricious daemons, no longer corresponded to man's better ordered life and his varied and specialized interests. The larger and more constant values of a social order based on agriculture required divine beings capable of responding to its wants, and the rise of polytheism was the answer to these religious demands. The polytheistic system was the expression of man's vision of the world, a world of diverse departments and manifestations though not a real unity. But polytheism marks an advance. For it helped (a) to liberate religion from its bondage to purely local associations. And (b), it replaced the colourless powers or *numina* of older belief by a number of divine beings of more specific character and with more or less definite spheres of activity. A god, as distinguished from a spirit, is a being with determinate qualities which embody the values of which men are conscious.

(1) *The Emergence of Gods.*—The formless spirits supply only a shifting and uncertain basis on which to evolve a god. It has been suggested that the Greek deities Hermes and Artemis were developed in this way, and the Roman goddess Juno has been construed as the general personification of the fertility *numen* or Juno of every woman. In any case such a process is infrequent. And the instances in which a totem has grown into a god, if they do occur at all, are extremely rare. What is clear is, that many of the greater gods have a connection with the phenomena of nature, and show traces of this relationship. Sometimes the connection is quite definite. Thus the Egyptian Ra and the Babylonian Shamash are sun-gods. The Greek Zeus, to whom corresponds the Vedic Dyaus, is a sky-god, and Ushas of the Vedic Hymns is a dawn-goddess. But there are many instances where the connection of a deity with nature cannot be precisely stated, though the general fact is not in doubt. Thus it remains uncertain what the natural basis of the Egyptian Osiris is; and we cannot say more of the Vedic Varuna and Vishnu than that they are connected with light and the heaven. The later development of a deity usually furnishes a very slender clue to his real origin. Moreover when the identification of a deity with a phenomenon of nature is transparent and precise, it is difficult for the god to develop by assuming new and higher qualities.

But while the greater phenomena of nature, by the fact that they possess a kind of physical universality, were a means of helping the mind to rise to the conception of deities of wider range and power, all gods are not to be explained thus. For some of them have their origin in the cult. The Hindu Soma is the power of the sacrificial libation, and Brahma the power of the sacrificial prayer personified. The Greek Hestia and the Roman Vesta (*q.v.*) have grown out of the sacred hearth as the centre of family life. Again, aspects of the cultural life, such as war and agriculture, have suggested deities who preside over them. In some cases men remarkable for their power and deeds have been exalted to the rank of divine, or semi-divine beings, *e.g.*, the Greek Herakles and Asklepios (*q.v.*). The motives which develop polytheism are complex.

(2) *The Characterization of the Gods.*—As social life expands, its values become more varied, and the representations of the gods gain correspondingly in content. A god takes on new qualities and aspects in response to the needs and desires of his worshippers, and this process appears in all religions. Few gods have acquired so varied qualities and offices as the Greek Apollo. His identification with the sun is comparatively late, and his original character obscure. But he came to figure as the lord of flocks and herds, the master of oracles and prophecy, the god of healing, of purification, and of poesy. The imaginative process which predicated diversified attributes to a deity at the same time expressed the interests and aspirations of his worshippers. And the cultus was the chief medium by which these tendencies were developed and took concrete form.

The problem of organization is urgent where a religion arises out of the fusion of different cultures. Conspicuous instances are Babylonian and Greek religion. The Semitic invaders of Babylonia absorbed the older Sumerian culture, and found a place for Sumerian deities within their own pantheon. Greek civilization, as we now know, was the result of a fusion of two races, a race of Aryan invaders with the "Helladic" race. And it is almost certain that some of the Hellenic deities, *e.g.* Athene, Artemis, and Aphrodite, were adopted by the Greeks from the older culture. Yet it is always hard to achieve organization in the religious complex of polytheism even when a fusion of cultures seems to render it essential. The local associations and the cult-interests of the dei-

ties of the conquered race resist absorption. This difficulty may be overcome by fitting them into the enlarged pantheon as sons or servants of greater gods. Even then the older cults and beliefs will linger on. Homeric religion is no doubt an example of organisation; but it is artificial and literary, it does not fairly represent the actual beliefs and cult-practices in Greece. Still, however imperfectly the process may work itself out, there is behind polytheistic religion an impulse towards order and system. The development of social life, with its well-marked departments and functions, prompted the mind to conceive the divine world after the pattern of the human. The needs of worship, where not dominated by magical ideas, led in the same direction. For worship at the higher level cannot be easily apportioned among a number of divine beings whose mutual relations are quite indefinite. Some order and gradation are necessary.

III. THE CULTUS IN HIGHER RELIGIONS

The cultus is the focus of a religion: here it is concentrated and symbolized. As the focus of religious life the cultus becomes the point at which the sense of the sacred is most concentrated and intense. Radiating from this centre the sacred suffuses associated elements, investing with religious significance things and persons, places and times.

(1) *The Sacred Place.*—In early religion a place or thing became sacred through the presence in it of a spirit or power: *numen inest.* But when men began to build houses, when the house became the centre of family life, the thought lay to hand that there must be a house for the deity to be the focus of his worship. So the temple arose, reared often on sacred spots or "high places," hallowed by immemorial associations. As the deity was supposed to be more intimately present in his temple, it often became a centre of oracles and prophecy.

(2) *Sacred Men: the Priesthood.*—To holy places correspond holy men. The priest has his precursor in the wizard of the lower culture. The priest is a man endowed with a special knowledge of the cultus, is possessed of ritual purity, and embodies in his person the power of the sacred. At first priestly functions were not the exclusive privilege of a class. The head of the family, or the king as head of the people, offers sacrifice, so in the old Hebrew and Roman religions. But with the growing value attached to sacred functions there was the tendency to assign the priestly office to a particular class, as in the Hebrew, Persian and Hindu religions. Nowhere have the priests formed a more strict and exclusive caste than in Brahmanism.

(a) *Prayer.*—Perhaps nowhere does the spirit of a religion reveal itself more intimately than in its prayers. Yet even in the higher religions the idea of prayer as the free outpouring of the soul to the divine comes late. Primitive prayer is closely allied to the spell, and it must take a fixed form of words to be effective. The elevation of prayer comes with the development of inner life and an enhanced sense of ethical and spiritual values. Some knowledge of the kind of prayers offered in the cultus may be gathered from liturgical forms, *e.g.* from the sacrificial hymns of the Gathas and the Vedas. Prayer as petition to the gods is universal. But only in a few religions do we find prayers containing confessions of sin *e.g.* in the penitential psalms of the Hebrew and the Babylonian religions. Nowhere is the mysterious potency of prayer so exalted as in Brahmanism. Here prayer becomes a cosmic power which constrains the gods, and is finally construed as the divine principle of things. But wherever prayer ceases to be the expression of a fundamental dependence on the Divine, it loses its essential meaning and value. An intrinsically efficacious form of words is really a reversion to the magic spell. (*See* PRAYER.)

(b) *Sacrifice.*—Sacrifice springs from a deep-rooted impulse of the religious nature. It plays a part in early religion, and is present in some form in all the higher religions. The purpose of sacrifice is to maintain and strengthen, or to restore, fellowship with divine powers, and it takes a central place in the cultus. In the burnt-offering the sacrifice is wafted to the gods. In the bloody offering the victim, through contact with the altar, becomes charged with the sacred, and its sprinkled blood has atoning virtue. The idea of substitutionary atonement is later and is due to reflection. In sacrifices of purification and atonement there is an ethical element which may lead to the higher development of religion. Just as with prayer, however, sacrifice may evolve in a way which is detrimental to the religious relation. What lifts sacrifice to an ethical and spiritual level is the conception of the righteousness of God. Where this obtains it is the inner side of the sacrificial act which is emphasised, the offering of the contrite heart and the obedient will. (*See* SACRIFICE.)

IV. RELIGIONS OF OBSERVANCE AND PROPHETIC RELIGIONS

The ritual aspect of religion tends to grow with the increasing complexity of the social order. When this tendency prevails religion takes on the specific character of legal observance.

(1) *Religions of Observance and Law.*—The idea of fixed observances or rules binding on the faithful develops where the idea of ritual purity is emphasised. The roots of the conception of the clean and unclean go back to primitive ideas of the sacred and of the dangerous with the associated apotropaic rites of expulsion. The growth of a sacral system leads to the fuller definition of the clean and unclean, and rules and forms are prescribed to preserve purity and remove impurity. In many higher religions there are detailed methods and a ritual of cleansing. In Roman religion we have lustration, which combined cathartic and apotropaic rites, and in Greece cathartic rites were specially connected with Apollo, the god of ritual purity. It is, however, in later Persian religion that rites of purification receive the most comprehensive and detailed expression, and nowhere is the notion of purity so dominant and pervasive. To all the numerous defilements that are possible correspond stated cleansings, and the Vendidad itself has been described as a kind of sin-codex. With this we may compare the laws of purity and impurity in the book of Leviticus, a book which embodies the cathartic ritual of post-Exilic Judaism. When a higher religion has developed a complicated system of ritual observance it brings the sense of the sacred into close and constant relation with the varied details of life. On the other hand, the religion itself is exposed to great dangers. The magical beliefs, which are a heritage of older religion, always tend to reassert themselves, and the religious rites readily degenerate to a mechanical performance which has intrinsic efficacy. When this happens the way to spiritual development is closed, and the later Persian and Jewish religions did not wholly escape the danger.

(2) *Prophetic Religion.*—Religion as piety has its centre within. The prophetic spirit proclaims this principle, and is itself the issue of personal and moral conviction. The prophet turns from the formal and external side of religion to emphasize its inner life, and when such a movement appears within a national religion it involves a loosening of religion from the social and political system. Great religious reforms and renewals arise from an individual or individuals for whom religion has become an intense and personal concern. Such a prophetic figure was Zarathustra. As we picture him from the Gathas he was a man of burning conviction, for whom Ahura Mazda was a supreme and moral deity whose cause is the right as against the lie. In this conflict the prophet calls men to fight and freely to choose the good. A like intense moral conviction and faith in the righteousness of Jahveh appears in the eighth century prophets of Israel linked with an even greater stress on the inner side of piety. The same note recurs in the teaching of Jesus that the vision of God is for the pure in heart.

It is curious to find an emphasis on the inner side of religion appearing within Hinduism. It emerges in the doctrine of Bhakti which has its classical expression in the *Bhagavad Gita.* Here we have the doctrine that trust and devotion, faith and love, to the divine power are a means of salvation. Religion assumes a personal colour. With Buddha this principle appears in the form of an extreme subjectivism. Within man himself lies the secret of salvation.

The work of the prophetic spirit makes possible the high stages of spiritual religion. Apart from its vivifying influence institu-

tional religion tends to grow formal and fixed, and its inner life to ebb. "Where there is no vision the people perish." The uprising of the prophet is a token that a religion which seems dead has still within it the springs of life.

V. REDEMPTIVE RELIGIONS

The prophetic movement is one symptom of the enhanced sense of personal and religious values, and the emergence of religions of salvation or redemption is another. Both indicate a slackening of the tie which binds religion to the national and political structure. For the official religion which men share simply as citizens of the state, a religion concerned with external observance rather than inner spirit and motives, no longer satisfies the more personal needs of which men are becoming aware. Corresponding to this increasing self-consciousness there grows up a craving for a more intimate and individual relation with the divine Power, a craving which the traditional religious forms cannot meet. And this feeling is deepened by the personal sense of the evils and sufferings of life. This longing for deliverance finds no fulfilment in the customary and external religion that a man inherits from his social group. Some better way is necessary; and the personal consciousness of the need of salvation carries with it a sense of responsibility for realizing it. So men seek some mode of expressing the religious spirit which shall embody their choice and preference, for religion must be in a more intimate sense their own. As the new movement takes its rise from broadly human needs, the form of religion which meets these needs cannot be merely local and particular: in its meaning at least it will be universal. This implies that the form of the religious relation is reconstituted, and this carries with it a differentiation of the religious community from political society. There now come into being religious associations or churches, where membership is based on a voluntary adherence to a particular religion or cult. This principle of a sacred society or church, clearly distinguished from secular society, is of great significance in the evolution of religion. For only under such conditions can the other-worldly or transcendent element in faith come to its due, and religion itself be delivered from bondage to political and secular interests. The idea of the sacred gains spiritual significance: the sacred community is united not merely in the observance of sacred rites but by a common disposition of the mind and will towards a religious good. And this good is not mundane but supramundane.

The new tendency finds expression in different ways. It appears as a movement which, without deliberately breaking with existing religion, takes form in religious associations which minister to felt religious wants. Again it appears as a philosophic gospel which offers spiritual deliverance to elect souls. Finally it manifests itself in the birth of a new religion, a religion which originates with a personal founder who proclaims a message of salvation. To the first class belong the various forms of Mystery-Religions which were common in Greek and Mediterranean lands from a period of eight centuries B.C. One of the best known is the Orphic Mysteries, a cult open at least to all Hellenes who underwent initiation. This cult held out the prospect of immortality and union with the divine. The body was a kind of tomb (*σῶμα*, *σῆμα*) from which the soul had to win deliverance. The way of salvation was by purification, abstinence and sacramental rites. The idea of something peculiarly sacred, in which the initiated participate, is common to Mystery-Religions. The later Mystery-Cults, like those of Attis, Isis and Mithras, which were widespread in Eastern Mediterranean lands in the post-Alexandrian period, set in the foreground the spectacle of the dying and reviving god. Their votaries, through baptism, purification and a sacramental meal, somehow shared in the being of the god and with him rose to new life.

In the philosophic sphere, Neo-Platonism proclaims the deliverance of the soul through an ecstatic union with the One that transcends rational thinking. Philosophic Brahmanism likewise has a doctrine of salvation, but a salvation through knowledge of the identity of the self with the Absolute or Brahman.

In Buddhism and in Christianity the spirit of redemptive religion is most fully expressed. In Buddhism the principle is seen taking an extreme subjective form. Buddha discards the metaphysics of Brahmanism, though he shares with it the idea that salvation comes through knowledge. The Enlightened, the Arahat, knows that thirst, with its attendant desire and suffering, is the evil of life, and by following the Noble Eightfold Way he advances to that indefinable goal, Nirvana. Redemption is thus a negative process: it is a gospel for the monk who breaks with the world rather than for the ordinary man who has to live in the world. Christian redemption is a richer and more positive conception. The deliverance sought is from moral evil or sin, and it is conditioned by repentance and faith. The end is not the extinction of personality but its enrichment through the power of a divine life, and it has corporate expression in life in the Kingdom of God which overcomes the evil in the world. Christian redemption is marked by its theistic basis, its sense of personal values and its positive character. The religious society of Buddhism is a monkish community: that of Christianity is the Church, or the fellowship of the faithful united in the service of God.

VI. PANTHEISM, MYSTICISM AND MONOTHEISM

These are features found only in the higher religious culture. They all claim to be an advance on some existing religious system.

(1) *Pantheism.*

Pantheism is in the main due to the development of reflective thinking. In the many it finds merely the passing appearances of the One. If pantheism is a late development, it was at least foreshadowed at earlier stages of religious evolution. Men soon became dimly conscious of a unity pervading the cosmic order and everywhere operative throughout it. In the Hindu conception of Rita and of Karma we have the idea of a power behind all things working by inflexible law. The ancient Chinese Tao conveys a sense of the eternal order and way of the universe. And the Greek Moira and the Persian Asha contain the same ideas. This belief in a universal principle, when applied to polytheism, leads to the notion of a common power behind the gods, and suggests that the various gods are only forms of the one Reality. Thus during the Middle Kingdom in Egypt reflective thinking treated the various gods as manifestations of Ra, and among the priesthood there was an esoteric pantheism.

The trend towards pantheism works itself out more readily when the gods are not sharply defined in their specific character and attributes. This was the case with the Vedic gods, since the qualities of one were often transferred to another. In the avatars of Vishnu one god assumes many divine forms. So by an easy process of transition the pantheism of the Upanishads and the Vedânta is reached. Here pantheism is thorough-going. All cosmic and psychical phenomena are unified in the one real Being: Brahman-Atman, the soul and the Absolute, are identical. *Tat tvam asi:* "that art thou." The multiplicity of the phenomenal world is only Maya or illusion; it disappears with knowledge. In contrast the clear-cut gods of Greece resisted a process of fusion. The Stoic pantheism, which identified Zeus with the universal and immanent reason or Logos, was rather an independent speculative theory than a development of Greek religion.

Religious pantheism is in the main a reflective development due to rational demands. If consistent, it is not a working religious creed, for it abolishes the religious relation by reducing it to an identity. (*See* PANTHEISM.)

(2) *Mysticism.*

Mysticism, like pantheism, in the strict sense is a phenomenon of highly developed religion. Individualistic in character, it is the outcome of a longing for intimate communion with the Divine. The Mystery-Religions show a mystic tendency in their doctrine of union with the god through the sacramental meal. The same is perhaps true of Hindu Yoga which is a method of inducing religious ecstasy by concentration and absorption of mind. The Yogin became for others a kind of supernatural being. But mysticism proper is a conscious reaction against the externality of a merely intellectual knowledge of God: its goal is a perfect union with the Deity in which the element of difference implied in thinking is overcome. The Neo-Platonic union of the

soul with the One is a purely mystical experience. The same spiritual movement appeared within Islam in Sufism, which no doubt was influenced by Neo-Platonism. The sufi sought to purge his mind of all that was not God, and the perfect man attained to absorption in God. The great mediaeval mystics sought the same consummation, an *unio mystica* achieved by transcending the form of thinking. Mysticism is loosely related to official and institutional religion. Possessing a "more excellent way," it can dispense with the recognized means of mediation. But if it invests religion with a new warmth and intimacy, it is deficient as a social power. And mysticism is always exposed to the danger of falling into pantheism. (*See* MYSTICISM.)

(3) *Monotheism.*

Monotheism is a late phenomenon of religion. The hypothesis of a primitive monotheism lacks foundation, and is intrinsically improbable. Beyond doubt the spirit and meaning of religion attain their fullest and best expression in some form of monotheistic faith. Polytheism disperses the religious interest: intimacy of worship and the confidence of trust are only possible when there is one, and only one, object of religious devotion. The trend towards monotheism was gradual, and it had preparatory stages. The first stage was what is called monarchianism. After the analogy of human society one deity is exalted above the rest, and becomes the king of the gods. A familiar example is the Homeric Zeus who stands supreme over all the gods and looks down on the conflicts of mortals among whom his will is accomplished. (Διὸς δ' ἐτελείετο βουλή.) The Babylonian Marduk and the Egyptian Ra are illustrations of the same phenomenon of one deity attaining a position of undisputed sovereignty. A rather more advanced stage is that of monolatry, where other gods are admitted to exist, but worship is reserved for one. This we find in Hebrew religion in the pre-prophetic period.

The earliest attempt—an abortive one—to introduce a pure monotheism, in this case a solar monotheism, is that of the Egyptian Amenhotep IV. in the XIVth century B.C. More impressive is the monotheism of Zarathustra, perhaps some eight hundred years before our era. This monotheism rests on a comprehensive view of the world. The physical and moral order derive from the one God, his will is right, and all the pure elements of life belong to his kingdom. The pronounced dualism of the later Avesta is absent from the prophet's teaching. With the eight century prophets of Israel the earlier monolatry became a true monotheism. This monotheistic universalism finds its clearest utterance in the work of Deutero-Isaiah. From this heritage of Hebrew religion Christianity derived its pure monotheism, and the same influence is manifest in the monotheism of Islam.

Monotheism is the ripest expression of the religious consciousness. It rests on the conviction that the ethical and religious values must have a sufficient ground, and this is the one God on whom all existence and value depend.

VII. REVELATION AND THEOLOGY

Belief in the communication of truth to man from a divine source is common in religions. This kind of communication usually concerns the future, and may be subject to a process of interpretation. Hence the practices of divination, the reading of omens and auspices, and star-lore. But the communication may be in and to the individual, for instance through visions and dreams.

(1) *Revelation.*

More especially is revelation thought to come through inspiration or "possession" by a divine power. The words spoken by the individual thus "possessed" are identified with the utterances of the god. The Greek Apollo was the god of prophecy, and the words spoken by his inspired priestess at Delphi were deemed to be the authentic voice of the god himself. The religious value of revelation depends on the character of the deity who is believed to reveal; and it is the consciousness of ethical values leading to an ethical idea of deity which purifies the content of revelation. Revelation in the large and comprehensive sense is linked with monotheistic religion. So Zarathustra proclaimed the message communicated to him by Ahura Mazda, and Mohammed in his visions had the truth revealed to him by Allah. The divine wor came to the prophets of Israel, and the preface to their messag was, "Thus saith the Lord." What they spoke Jahveh had cause them to know. At this level revelation centres in an experienc or illumination within. But these inspired utterances were after wards written down and collected: in the form of sacred book they came to be regarded as objective statements of divine truth Hence the claims made for the Avesta, the Veda, the Koran, an the Old and New Testaments. Books which were accepted a statements of revealed truth naturally became authoritative, an as expressing authoritatively the content of a religion they fur nished a basis for theology. (*See* REVELATION.)

(2) *Theology.*

Theology grows out of the beliefs contained in an historic re ligion: it is an endeavour to state what is involved in a definit religious type of experience in general propositions or doctrines The earliest anticipation of this is the myth framed to explain th meaning of something done in the cult. Theology is not detache like speculation, it is a natural and necessary outgrowth from th life of religion itself. It is the product of a mature religion, an commonly has its basis in the sacred books which record its re ligious experience. We find theological developments in Judaism and Buddhism, but in a more complete form in Islam and i Christianity. The Islamic and the Christian theologies clain to interpret the authoritative revelation contained in their sacre scriptures. In both instances the growth of theology was stimu lated by the presence of beliefs judged to be heretical. Th Mutazalite movement, with its doctrines of faith and free-will an its criticism of tradition, impelled the orthodox party in Islam t define the true doctrine of Allah and his attributes. In a like wa the Gnostic heresies provoked the growth of a Christian theolog which sought to expound the doctrines involved in Christian faitl and practice. The Islamic conception of religion, however, is to much interwoven with what is external and political to furnish favourable field for theological development. Christianity, on th other hand, has developed a body of religious experience of wealth and amplitude capable of sustaining an impressive body o doctrine.

The function of theology is primarily to interpret. As con trasted with speculation it leans on authoritative revelation, an stands in organic relation to a specific historic religion. (*Se* THEOLOGY.)

VIII. ETHICS AND ESCHATOLOGY

The ethical element is of fundamental importance in determin ing the quality of a religion: it is a powerful factor in elevatin the object of worship, the religious relation, and the religious life At the pre-deistic stage the sacred is interpenetrated with magica beliefs, and ethical principles have their lowly precursor in th sanctity of tribal custom. When through the growth of socia culture the moral virtues are recognized as values, they are mad to qualify the character of the gods.

(1) *Ethics.*

The process may not be easy when the deity has a pronounce natural basis, but still it does occur, as in the case of the Vedi Varuna and the Babylonian Shamash. On the other hand, th Persian Ahura Mazda became a definitely ethical god who de mands pure living and right thinking. At a later date Mithra wa revered as the god of truth and loyalty. The Greek Zeus ac quired moral functions, and Δικη, or Justice, was proclaime to be his daughter. The feeling for the moral element in religio appears in the saying of Euripides: "If the gods do aught that i shameful, they are no gods." A profound appreciation of th moral values is seen in the Hebrew prophets who passionatel declared that Jahveh is a righteous God who demands right eousness in his people. And when men cherish the conviction tha the divine Power is righteous, the efficacy of sacrifice is made t depend on moral conditions.

Through the interpenetration of ethics with religion the sphere of the sacred is enlarged, and the moral life becomes an aspec of the religious vocation. Moral laws rank as divine commands and ethical duty as a religious obligation. On the other hand, wher the notion of divine personality is weak or lacking, ethics inevi-

tably assume a worldly or a negative character. Chinese religious ethics, for instance, founds on the idea of Tao or world-order, and man's duty is to reflect this order in his life. The ethical ideal is one of conformity, propriety and measure. A like utilitarianism is present in the Roman *pietas*, the knowledge of the *jus divinum* which enables a man to keep on profitable terms with the divine powers. The negative conception of ethics is strongly marked in Buddhism, which, in its original form, had no deity. The ideal of the Arahat is merely an ascetic discipline by which the dominion of desire and sense may be extinguished and Nirvana attained. In strong contrast is Christian ethics which rests on an ethical monotheism. Here the ideal is positive, the development of man's ethical life as a member of the Kingdom of God.

(2) *Eschatology.*

The problem of eschatology is the ultimate destiny of man and the world. It is a problem which lies in the background of the religious consciousness, though eschatological motives may powerfully affect the working of religion. Thus eschatology looms large in the old Egyptian, the Christian and the Islamic religions, but it plays a feeble part in the Babylonian, the old Hebrew and the early Greek religions. There is no side of religion where the survival of old ideas is more apparent, or where the presence of inconsistent elements is more conspicuous. This is intelligible; for eschatological ideas do not lend themselves to verification in religious experience, and they offer an ample field for religious imagination.

Primitive eschatological ideas gather round the fate of the dead, and are unleavened by ethical elements. Two factors promote the growth of eschatology in higher religions, a quickened moral consciousness and the sense of the value of the individual. If ethical ideas, however, be cast in a utilitarian mould, the eschatological interest may be slender; and even though they are of a higher order, as in Hebrew Prophetic religion, the merging of the individual in the people as the religious unit has the same result. Post-Exilic Judaism gained a new sense of the value of the individual, and felt the need of retribution, and this led to decided eschatological developments. In Buddhism, where ethics are negative and personality an obstruction rather than a value, eschatological doctrine is nebulous in the extreme.

Of the ethical ideas which promote eschatology the most prominent is that of justice, for it directly suggests the notion of future rewards and punishments. Justice, it is felt, is only imperfectly done on earth. The Osiris-Religion of Egypt figured the soul of the dead man ushered into the judgment-hall of Osiris, where his deeds were weighed in a balance. Those who pass the test go to serve Osiris in the fields of Earu. In the Avesta, Shraoshi, the guide of souls, is said to lead the just over the heavenly bridge to the gate of paradise. Orphism taught that the initiated were rewarded by a happy life in the Elysian Fields, while the wicked were cast into Tartarus. In the Persian, Christian, and Islamic religions, along with the judgment of the individual there is conjoined the idea of a world-judgment and the final separation of the good from the wicked.

The fuller development of eschatological doctrines belongs to the ethical and redemptive religions. But no religion has done this consistently, and eschatology remains the most backward aspect of religion. Here the material and the ethical, the sensuous and the spiritual, are often incongruously blended, and old beliefs survive in an alien environment. The Islamic eschatology, for instance, is on a lower level than that of a religion of salvation. And Christian eschatology, at least in its traditional form, is only imperfectly spiritualized. The problem of a consistent eschatology is a difficult one. (*See* ESCHATOLOGY; IMMORTALITY.)

IX. CLASSIFICATION OF RELIGIONS

Various attempts have been made to classify religions, but with only partial success, and there is no generally accepted scheme. Every religion is a complex of many elements, and there is no one specific feature which adequately characterizes it. One of the earlier classifications is that of Hegel into Nature-Religions, Religions of Spiritual Individuality, and Absolute Religion. But he arbitrarily groups together very disparate materials, and in the light of modern knowledge the scheme is unworkable. Edward Caird's revision into Objective, Subjective, and Absolute or Universal Religion is less open to this objection, but it is too vague and too much dependent on a particular philosophic construction of religion. Tiele adopts a very broad classification into Nature-Religions and Ethical Religions, while Siebeck groups religions into Primitive Religions, Morality-Religions, and Redemptive Religions. The latter scheme is certainly suggestive, though the distinction between ethical religions and redemptive religions can hardly be carried out consistently. Even the broad distinction between natural and ethical religion would have to be applied rather arbitrarily.

In the classification of religions into Tribal, National, and Universal, the line of demarcation is much more distinct and can be more easily used. But it may be objected to this classification that it is based on a principle which gives no clue to the character and content of the religions. Moreover it may be said that no religion is *de facto* universal. And from an evolutionary standpoint it is a defect in a classification that it ignores the principle of valuation.

The complexity and variety of the materials render a complete and consistent classification impracticable. But it is always possible to apply different criteria in surveying the religious field. Religions may be grouped according to their conception of the Divine, according to the types of piety they foster, or according to the ideal after which they strive. But such classifications will be merely provisional: though suitable for the purpose on hand, they cannot claim to be comprehensive and final.

BIBLIOGRAPHY.—Monographs dealing with particular religions will be found under the respective headings. The literature on religion is vast, and only a few of the works likely to be useful are noted here.

(a) *Histories of Religion.*

The most compact and complete history, embodying the results of recent research, is the *Lehrbuch der Religionsgeschichte*, edited by Bertholet and Lehmann, 2 vols. 1925. G. F. Moore, *History of Religions*, 2 vols., 1914, 1920. A. Menzies, *History of Religion* (1st ed., 1895, and later editions). Toy, *Introduction to the History of Religions* (1913). The *Religionsgeschichtliche Lesebuch* (1908), ed. by Bertholet, gives a translation of extracts from the chief religious classics. A new edition is appearing. There is also the *Textbuch zur Religionsgeschichte* (1912), by E. Lehmann.

(b) *The General Development of Religion.*

E. Caird, *The Evolution of Religion* (1894). Tiele, *Elements of the Science of Religion* (2 vols., 1897 & 1899). Bousset, *Das Wesen der Religion* (1904); Galloway, *Principles of Religious Development* (1909). King, *The Development of Religion* (1910). Farnell, *Greece and Babylon* (1911), and *Attributes of God* (1925). Wundt, *Mythus und Religion* (1909). G. F. Moore, *The Birth and Growth of Religion* (1923). Some works of more restricted scope are valuable for the light they cast on religious development, *e.g.* W. R. Smith's *Religion of the Semites* (3rd ed. 1927), Nilsson's *History of Greek Religion* (1925), and Warde Fowler's *Religious Experience of the Roman People* (1911).

(c) *Psychology and Philosophy of Religion.*

For the Psychology of Religion James's *Varieties of Religious Experience* (1902), Stratton's *Psychology of the Religious Life* (1911), Pratt's *The Religious Consciousness* (1923), will be found useful, and other works equally deserve mention.

Hegel's *Philosophie der Religion* (1840) is historically important. Among other works on the subject are those of J. Caird, Rauwenhoff, Höffding, Siebeck, Pfleiderer, Galloway and Ladd. (G. GA.)

RELIGION, WARS OF (1562-1609). The so-called Wars of Religion opened with the massacre of sixty Huguenots at Vassy in 1562, and ended with the declaration of the twelve years' truce between Spain and Prince Maurice of the Netherlands in 1609. They included eight civil wars in France, the revolt of the Netherlands, and a number of less important rebellions. Though outwardly religious in character, inwardly they were influenced by economic and financial causes, constituting as they did a revolt against the fiscal policy of the mediaeval papacy.

Causes and Personalities.—During the Crusades the Church became an all-controlling power, establishing its own law courts, its own tax collectors and its own prisons in nearly every European country. As long as the various kings were occupied in mastering their feudal nobility the papacy remained all-powerful, but once control over them was established the next conflict was between the more progressive of the kings and the pope. This

quarrel centred round the questions of appointments, taxation, "benefit of clergy" and the interference of the pope in national government. In 1296, Edward I. of England demanded one-fifth of the personal property of the clergy, and four years later Philip the Fair of France openly quarrelled with Boniface VIII. over taxation. A religious-economic conflict then began which lasted until the peace of Westphalia in 1648.

In England, John Wycliffe began to preach reform about 1366. Eleven years later the papacy moved back from Avignon to Rome, and the whole question of papal control was thrown into the melting pot. Then arose the question of whether a general council of Christendom was not superior to the papacy. This question gave rise to the Council of Constance in 1414, which, in 1415, condemned Hus, a Bohemian reformer influenced by Wycliffe, to be burnt. This in turn brought about the Hussite wars (1419–1436)—the forerunner of the wars of religion.

By the opening of the 16th century discontent against the Church was general, especially so in Germany, and all that was wanting were leaders. These, as is always the case during revolutionary periods, soon came to the fore. The most prominent were Erasmus, a Dutchman (1469–1536); Luther, a German (1483–1546); Zwingli, a Swiss (1484–1531), and Calvin, a Frenchman (1509–1564). Erasmus was an evolutionary, he believed in a slow and steady change; Luther was the reverse, he wanted immediate change, and his doctrine of "justification by faith" sent a thrill of horror through the Catholic Church. He was a democrat and an economist as well as a religious reformer. He attacked "indulgences," and said: "Since the pope is rich as Croesus, why does he not build St. Peter's with his own money, instead of taking that of the poor man?" In 1520 he was excommunicated, and this same year at Wittenberg he threw the Papal bull into the flames. He was of opinion that the power of the papacy rested on money, and if money were withheld in two years the papacy would vanish.

Turmoil.—The results of his teachings led to a peasants' war in Germany in 1525. In Switzerland, Zwingli (the originator of the name Protestant) attacked the Church, and the first conflict between Protestants and Catholics took place at Kappel, in 1531. In France Calvin's doctrines, based on the infallibility of the Bible in place of that of the Church and pope, gave rise to the Huguenot and Presbyterian movements. Meanwhile, in England, out of Henry VIII.'s first divorce arose a quarrel with Rome which ended in 1534 in the revolt of the English Church from the pope and in the closing of the monasteries, whereby Henry enriched himself.

The greatest part of Europe was now thrown into a spiritual and economic turmoil. On one side stood religious freedom confronted by papal infallibility, on the other fiscal control faced by papal anathema. Nations, cities, villages and families were divided. A general Council of the Church was held at Trent in 1545, but the Protestants refused to attend. The "Society of Jesus," founded by Loyola in 1538, gained strength, its scientific system of propaganda rousing the fury of the Reformed Church.

Hostilities in France.—The first clash came in France which had been stirred by the preaching of Lefevre (1450–1537). Henry II. (1547–1559) swore to extirpate the Protestants, and burnt them in hundreds. He was succeeded by his son Francis II., a boy of sixteen married to Mary Queen of Scots. As Francis was too young to rule, the duke of Guise put himself at the head of the army, and when Francis died, in 1560, the duke was reluctant to surrender his power so that a conflict soon arose between him and the Huguenots under Coligny, merging, in 1562, into the First Civil War. An indecisive battle was fought at Dreux; then two other civil wars followed, in which battles were fought at St. Denis in 1567, and Jarnac and Moncontour in 1569. These were concluded by the peace of St. Germain, according to which the Huguenots were to be tolerated, Coligny being received on friendly terms by Charles IX. of France and his mother, Catharine de' Medici.

The Catholic party of the Guises, determining to put an end to this friendship, plotted and carried out the massacre of St. Bartholomew on August 23, 1572. The result was the Fourth Civil War which was followed by the fifth, sixth, seventh and eighth. The last of these known as the war of the three Henrys—Henry III., Henry of Navarre and Henry of Guise—ended with the assassination of the first and third, leaving Henry of Navarre, now Henry IV., the national hero. In 1590, he won the battles of Arques and Ivry, and to put an end to the war, in 1593, re-entered the Catholic Church. In 1598, he issued the Edict of Nantes by which the Calvinists were permitted to worship as they chose, and to be eligible to hold government appointments. Meanwhile an even more terrible war was being waged in the Netherlands.

Spain and the Netherlands.—In the second half of the 16th century, the chief ally of the pope was Philip II., son of the emperor Charles V. Charles though a firm Catholic was not a fanatic; Philip's attitude was very different, for he was willing to sacrifice everything so long as the Protestants were exterminated. In 1555 Charles abdicated, handing over his Habsburg possessions to his brother Ferdinand, and Spain, the American Colonies, the Two Sicilies and the Netherlands to his son Philip. For ten years the Dutch suffered Philip's rule. Then in 1566, five hundred of the nobles protested against his policy. Thereupon Philip sent the duke of Alva to the Low Countries. William of Orange fled to Germany and thousands of Flemish weavers sought refuge in England. Alva's administration was a veritable reign of terror. Though not unaccustomed to persecution, for Charles V. had burnt many of them, the people revolted and found their leader in William, Prince of Orange and Count of Nassau (1533–1584), who in 1568 collected together a small army and opened the wars of religion with Spain. Defeated again and again he was never conquered, and in 1572 the northern provinces of Holland chose William as their governor.

After six years of tyranny Alva was recalled, but this did not improve things as his leaderless soldiers committed every possible atrocity. The north, guided by William, now refused to recognise Philip as their king, and the Union of Utrecht followed in 1579, by which the United Provinces were constituted. Two years later these provinces declared themselves independent of Spain. Philip realising that William was the heart and soul of the revolt offered a patent of nobility and a large sum of money to anyone who would assassinate him, with the result that the great patriot was shot at Delft in 1584.

His son, Maurice of Nassau (1567–1625) succeeded him, and was made stadtholder. When Queen Elizabeth of England decided to send troops to his assistance, Philip was so enraged that he determined on the conquest of England, and, in 1588, equipped and despatched the "Armada." Its defeat and destruction as well as the failing resources of Spain were of the greatest assistance to Maurice, who soon showed himself to be a general far in advance of any of his contemporaries. A great campaign was fought in 1597. From then onwards to 1609 battles were waged and sieges undertaken, and though Maurice was by no means always successful, as was notably the case in 1605, the power of Spain was definitely on the decline, and in 1609 a twelve years' truce was concluded and the United Provinces took their place in the European system "as a free and independent State."

This truce was but an interlude in the struggle for freedom, for in 1618 the Thirty Years' War (*q.v.*) broke out, and it was not until it ended with the Treaty of Westphalia in 1648, that once and for all the semi-religious conflict of nearly 100 years was brought to an end, Europe emerging out of the night into the daylight of modern history.

BIBLIOGRAPHY.—The bibliography of this period is extensive, and the reader is referred to *The Cambridge Modern History*, vol. iii., 1904, and especially to the full list of books at the end of the volume.

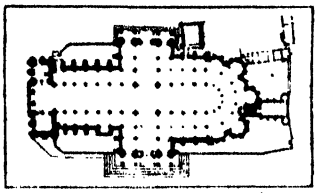
RELIGIOUS AND MEMORIAL ARCHITECTURE.



The earliest religious buildings were not so much congregational as shelters for the mysteries or provisions for the rite, sometimes consisting merely of an altar; and the earliest memorials were a stone or a mound. Even the Egyptian temple, with its court guarded by pylons or towers and approaching avenue of sphinxes or colossal human figures, was a sanctuary for kings and priests

rather than a place of worship for the people; and the pyramids were the tombs of kings, furnished with the necessities of the future life (*see* EGYPTIAN ARCHITECTURE). The Greek temple, with its central shrine for a statue of the god or goddess, porticoes to front and rear, and flanking colonnades, was more like a place of worship as we understand it to-day. It was at least a public building. Greek memorials were generally tombs (*see* GREEK ARCHITECTURE). The Roman temple, of which the construction was determined by the blending of the Greek columnar system with the Etruscan arch, came nearer than the Greek to the Christian church in plan; the *cella*—used as a treasury or as a museum of sculpture and frequently occupying the whole width of the building—corresponding to the chancel or sanctuary, and the deep portico and steps of the entrance anticipating the west front. A favourite form of Roman memorial, reflecting a proud spirit, was the triumphal arch (*see* ROMAN ARCHITECTURE).

Early Christian and Mediaeval.—It is probable that the earliest Christian churches, in countries under Persian rule, were humble structures of wood, clay, or at the most brick concrete, in the form of a shrine for an altar where two or three might be gathered together. Such churches, of which remains have been found in Syria, Palestine, Armenia and north Africa, were concentric in plan—that is to say, square, circular, octagonal or cruciform—and roofed with a dome. With the conversion of Rome to Christianity in the 4th century, and the establishment of Constantine's new capital at Byzantium, a more congregational form of church was evolved by adjustments between the domed, concentric shrine and the plan derived from the Roman basilica, or hall of justice. In the Eastern empire the interactions between East and West were extremely complicated, and authorities still differ about the respective shares of Greek, oriental and Roman influence in forming the religious architecture that we call Byzantine. The result, however, was a square, circular, octagonal or cruciform church of brick and concrete, with a central space covered by the principal dome, and arms or extensions covered by subsidiary domes. One arm was provided with an apse for the altar—now removed from the centre of the building—and another with a narthex, or porch. Decoration took the form of a continuous sheathing or "skin" of marble and mosaic. St. Sophia, Constantinople, and St. Mark's, Venice, are famous surviving examples.

In the Western empire development was simpler, and the earliest Christian churches in Rome itself were copies or even adaptations of Roman buildings, frequently embodying fragments of pagan temples in their construction, following, with internal modifications, the plan of the basilica. The usual arrangement of basilican churches was that of nave and aisles, divided by arcades, with a semi-circular apse for the altar and a choir enclosed by low screen walls at one end, and a covered narthex, or porch, preceded by an open court, or atrium, at the other. From the basilica, with some reflection from the East, was evolved the form known as Romanesque. The addition of transepts and the prolongation of the sanctuary resulted in a cruciform plan, and the flat wooden roof of the basilica was gradually exchanged for vaulting in stone. In northern Italy conditions favoured a mixed style, so that it is sometimes difficult to say whether a particular building should be described as Byzantine or Romanesque, but in passing down the Rhine and extending into France and Germany Romanesque became more clearly defined, reaching England finally in the form we know as Norman. (*See* BYZANTINE AND ROMANESQUE ARCHITECTURE.)

Gothic, which may be dated from the 12th century, proceeded logically from Romanesque by the substitution of the pointed for the round arch and the development of rib vaulting—changes which enabled unequal spans to be vaulted to the same height and smaller units of inferior materials to be used for filling the spaces between the ribs. With the progress of Gothic the onus of stability tended to be put more and more upon the stone skeleton, with its elaborate system of thrust and counterthrust, the downward pressure of the nave vaulting being met externally by buttresses and flying buttresses, while the inactive wall-spaces were pierced by larger and larger traceried window openings filled with stained glass. Architecturally the Gothic church was a collaboration of many kinds of craftsmen—masons, carvers, painters and glaziers—organized into guilds and working more or less "freehand" under a master mason, and ecclesiastically it was adapted to the requirements of a powerful priesthood. Its characters can be studied to advantage in Chartres and Reims cathedrals in France, and Westminster Abbey and Canterbury and Wells cathedrals in England. Gothic memorials were almost exclusively religious, in such forms as "Eleanor" and market crosses (*see* GOTHIC ARCHITECTURE). In the 20th century the Gothic, because of its aspiring verticality, has sometimes been adapted to tall, non-religious buildings (*see* ARCHITECTURE).

FIG. 1.—PLAN OF CHARTRES CATHEDRAL

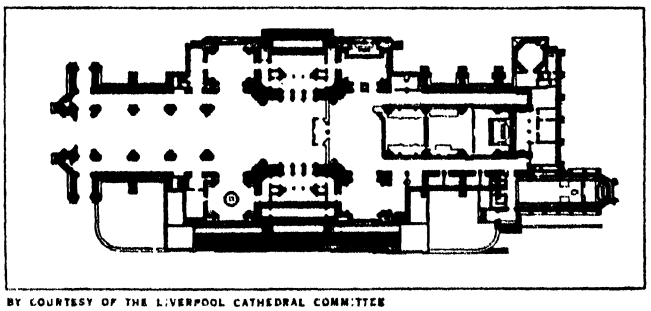
Renaissance.—In Northern Europe, at any rate, the Renaissance and the Reformation went hand in hand in deciding the form and character of churches. As was natural, the revival of Roman architecture began in Italy, where the tradition survived, and it gradually spread to the rest of Europe with local modifications due to the resistance of native styles. For our purposes the critical example is St. Paul's cathedral, designed by Sir Christopher Wren and built between 1675 and 1710. Disliking Gothic, which he called "barbarous," Wren observed that the chief requirement of the Reformed religion was a preaching space or auditorium. His first design for St. Paul's was a Greek cross in plan, and though clerical opposition compelled the adoption of a Latin cross he carried out his ideas to some extent in the great space under the dome at the crossing of the transepts. His other city churches, of which St. Stephen, Walbrook, and St. Mary-le-Bow are examples, were frankly rectangular sermon halls with at most a shallow recess for the communion table. The plan of church introduced by Wren persisted through the 18th century, as may be seen in St. Mary, Woolnoth, by Wren's pupil Hawksmoor, and St. Martin-in-the-Fields and St. Mary-le-Strand, by James Gibbs.

Even on the Continent, in countries untouched by the Reformation, the revival of Roman architecture restored a similar plan, as we see in the Pantheon and the churches of St. Sulpice and the Madeleine, Paris. In Italy and Spain the Renaissance passed into Baroque, with its free handling of form without reference to construction, and florid ornament, characters which have been associated with the religious movement known as the Counter-Reformation (*see* BAROQUE ARCHITECTURE). The memorials of the Renaissance period are chiefly sculptured tombs, in which Christian and classical sentiment are blended (*see* RENAISSANCE ARCHITECTURE).

FROM BIRCH, "LONDON CHURCHES OF THE 17TH AND 18TH CENTURIES" (BATSFORD)

FIG. 2.—PLAN OF ST. MARY-LE-BOW

In England the general tendency of the Renaissance in church designing was interrupted by the Gothic revival. Its earliest phase, like that of the Renaissance itself, appears to have been purely literary and romantic, but as time went on it became associated with the definitely religious Oxford Movement of High Anglicanism. Contributing causes were undoubtedly the scientific materialism of the 19th century, which sharpened and stiffened the religious attitude in opposition, and the observed effects of the industrial revolution, which made men like Ruskin look for a remedy in the revival of handicrafts (*see* MODERN ARCHITECTURE: *18th and 19th Centuries*).



The Orient.—The many examples of religious and memorial architecture in the countries of Asia are treated in the articles CHINESE ARCHITECTURE; INDIAN ARCHITECTURE; JAPANESE ARCHITECTURE; MOHAMMEDAN ARCHITECTURE. It is interesting to note here that the aspiring quality of the Gothic is also expressed in religious architecture in the Orient.

THE MODERN PERIOD

For present purposes the modern period may be regarded as the last 50 years, with special emphasis upon the first quarter of the 20th century. When considering the causes which led to the more practical designing of churches after the Gothic revival we are inclined to give first place to the decline of materialism as a respectable philosophy and the consequent easing of the conflict between science and religion. Pressure removed, there was not the same need for the church to insist upon the outward forms of its past. At the same time there was a change in the spirit of industry. It began to be recognized that though craftsmanship—in the mediaeval sense—could not be revived, self-interest required that mechanical skill should be given its best opportunity. The result, in religious architecture, was a broader system of planning, to the actual requirements of the religion of the day rather than to advertise its historical claims, and a more intelligent use of the mechanical skill that survived, instead of a hankering after a craftsmanship impossible to restore.

Great Britain.—The first important result of the new spirit in religious architecture in Great Britain was the Roman Catholic cathedral of Westminster, designed by John Francis Bentley (1839–1902) and begun in 1894. Bentley himself would have preferred a Gothic design, but several good reasons were given for the Byzantine building decided upon: a wide nave and a view of the sanctuary best adapted to the congregational needs of a metropolitan cathedral; economy—since the whole space could be covered and the whole building erected, apart from decoration and ornament, which in other styles would form a substantial and costly part of the structure itself; avoidance of hopeless competition with Westminster Abbey; an opportunity to suggest an international character by the use of a style associated with inclusive primitive Christianity up to the 9th century. Externally Westminster cathedral is remarkable for its tall campanile, and for the bold use of brick and stone in alternating bands. The interior consists of a vast nave of three bays, 60 ft. square, each surmounted by a saucer-shaped concrete dome. A fourth bay, with a more elaborate dome, 52 ft. in diameter and pierced for the admission of light, forms the sanctuary, and behind it is the apse, with a raised retro-choir visible from the whole of the nave. Each bay of the nave is divided by lesser piers and again by monolith columns, forming an arcaded aisle.

With Liverpool cathedral, designed by Sir Giles Gilbert Scott, R.A. (b. 1880) at the age of 22, and begun in 1904, there was a return to Gothic, but Gothic with a difference. Liverpool cathedral is an example of designing in mass instead of in line, the style being a free interpretation of Decorated or 14th century Gothic (*see* DECORATED PERIOD) and the material a warm red

BY COURTESY OF THE LIVERPOOL CATHEDRAL COMMITTEE

FIG. 3.—PLAN OF LIVERPOOL CATHEDRAL

sandstone, with dressings of lighter stone. Standing on the summit of a rocky mass, St. James's Mount, in the heart of the city, the building when completed will consist of a central square space rising into a great tower crowned with an octagonal lantern, with eastern and western transepts and two oblong extensions, nearly equal in length, forming the nave and choir. In a side view the central mass formed by the tower and transepts will be absolutely, and the whole building nearly, symmetrical, the choir having a different termination to that of the nave. A striking feature of Liverpool cathedral is the great size of the bays which make up the nave and choir—three only occupying the space which in older buildings would be divided into something nearer ten. Each bay is lighted by a single two-light window, and the aisles are reduced to passage-ways through the return walls, continuous with the buttresses outside, which divide the bays.

In the space of a short article dealing with the modern religious and memorial architecture of the world it is not possible to select more than a few significant examples, preferably those with the most modern characteristics. From this point of view there is a special interest in churches associated with town-planning schemes (*see* TOWN AND CITY PLANNING). Earliest in order of date are the church of St. Jude's-on-the-Hill and the free church in the Hampstead garden suburb, designed by Sir Edwin Lutyens R.A. The strongly domestic flavour of these, with their deep tiled roofs and cornices at the level of those of the surrounding houses, is in keeping with the communal ideals of a garden suburb. Naturally it is in the neighbourhood of London, with its rapid growth of population, that some of the most characteristically modern churches are to be found. St. Catherine Coleman, Hammersmith, designed by Robert Atkinson F.R.I.B.A., is essentially a rectangular auditorium with short chancel, both barrel vaulted by means of steel arches embedded in concrete, faced externally with London "stock" bricks and roofed with pantiles, and finished off internally with a surface of rough plaster. The stylish allusion is Byzantine, which appears to be the natural consequence of brick and concrete building for congregational needs. Within a few hundred yards of St. Catherine Coleman there is an exceptionally beautiful church, St. Saviour's, designed by Edward Maufe F.R.I.B.A. for the Royal Association in Aid of the Deaf and Dumb. In this church, which is of brick in a free interpretation of Decorated or 14th century Gothic, everything is adapted to sight to the exclusion of hearing. There is no organ and no provision for a choir, the clergy seats being in two "ambos" set at an angle to keep the occupants in full view, the nave walls splay in to the chancel, the floor rakes as in a theatre, and there is a western gallery. A feature of the interior is restful colour decoration.

St. Barnabas mission church, Dalston, designed by Prof. C. H. Reilly F.R.I.B.A. and built about 1910, is an example of an urban building so closely surrounded that it can be seen only as an interior. This, of London "stock" bricks, is of almost startling grandeur; the brick being used, not as by Bentley at Westminster as a support for marble sheathing, but for its own decorative effect; the full colour value being brought out by the use of white metal instead of brass for candlesticks, chancel gates and other fittings. Unlike most modern churches below cathedral rank, St. Barnabas has what amounts to a choir, formed by the crossing of the shallow transepts, saucer-domed in concrete above and separated from the barrel-vaulted nave of three bays by a wooden screen of four columns supporting the rood beam. The special point about St. Andrew's, Ilford, designed by Sir Herbert Baker, A.R.A., is that it is an exercise in brick and timber construction, giving full opportunity to the native craftsmanship in these materials, the only stone employed being in the chancel flooring, the corbels supporting the roof timbers and the font. Characteristically modern is the addition of decorative details by prominent artists and craftsmen; an altar and reredos carved by Lawrence Turner, a triptych painted by Colin Gill, a lunette of glazed pottery—in the baptistery—by the Poole Potteries, and, externally, a bronze figure of the angel of peace by Charles Wheeler.

Mention must be made of a few other recent churches in England of special architectural interest. In the neighbourhood of Liverpool and elsewhere Sir Giles Gilbert Scott has designed several churches in his characteristic manner of moulded Gothic—as it might be called in distinction from the stone skeleton construction of the middle ages—St. Paul's, Derby lane, Liverpool, being a good example.

As an instance of planning to requirements, combining the maximum of space and unimpeded movement, sight and hearing with a dignified architectural effect, special mention must be made of the new church at Hindley, Lancashire, designed by Robert Atkinson F.R.I.B.A.

With the exception of Westminster cathedral which has already been described all the buildings we have been discussing belong to the Established Church of England. To a certain extent the characters described—congregational plan, and construction in terms of contemporary labour and most readily available materials—are common to the modern churches of all creeds and sects, but every creed has its particular requirements. Naturally the Roman Catholic Church puts the emphasis upon its Roman tradition, with a preference for the basilica form, and the somewhat exuberant Baroque of the Brompton oratory, by Herbert A. K. Gribble, finds more sober echoes elsewhere. Beyond dispensing with the chancel the Protestant Free Churches of England do not follow the lead, peculiarly suitable to their requirements, given to them by Wren, but rather surprisingly cling to Gothic, though here and there, as in the Broadway Congregational church, Hammersmith, by Cecil M. Quilter, the plan of the sermon hall is frankly adopted.

Christian Science, however, has followed a bolder policy, and all its churches in England are designed as auditoriums, with a platform for the "readers" and a screened organ chamber in place of a chancel, and generally a raking floor, as in a theatre. One of the most recent examples, the Eleventh Church of Christ, Nutford place, Bryanston square, by Oswald P. Milne F.R.I.B.A., seems to have arrived at a perfect adjustment between form and requirement, and is in every respect an admirable building, proclaiming at a glance its purpose and construction as an auditorium with a very wide span of roof, buttressed at each corner by a tower-like bastion or pavilion containing a staircase. The interior, which will seat 900, is designed to allow complete circulation of the building without disturbing the congregation.

In memorial architecture the most extensive work in England during the period under review is the memorial to Queen Victoria, in front of Buckingham palace, designed by Sir Aston Webb R.A. Otherwise the memorial architecture of the period resolves itself inevitably into war memorials. Of these by far the most important, by reason of its wide appeal, is the cenotaph in Whitehall, designed by Sir Edwin Lutyens R.A., the stone of remembrance by the same architect, and the memorial cross by Sir Reginald Blomfield R.A. Modifications and combinations of these three architectural forms have been used as war memorials in several provincial centres.

Many war memorials, however, have taken the form of halls and chapels, either as new structures or as additions to existing buildings. The Scottish national war memorial is a reconstruction of part of Edinburgh castle, designed by Sir Robert Lorimer, A.R.A. On the site of an old barrack, and improving the general outline of the castle from a distance, the memorial is in the form of the letter E, with a heptagonal shrine, containing the memorial casket supported by a marble table, projecting at the back in line with the middle limb, which thus forms a porch allowing a vista into the shrine. The stem of the E forms a gallery of honour, with a bay for each of the 12 Scottish regiments; and, by means of stained glass, moulded bronze, carved stone and wood, metalwork and painting, the place is made a museum of illustrative symbolism—not only every type of soldier and the women's services, but even animals and carrier pigeons and the actual arms and materials used in the War being recorded.

Though not on English soil, reference must be made to the several important memorials designed by English architects for war areas in France and Belgium. Three in particular claim attention: the memorial to the missing at St. Quentin, by Sir Edwin Lutyens R.A.; the Menin gate memorial to the missing, Ypres, by Sir Reginald Blomfield R.A.; and the memorial to the missing, Ploegsteert wood, by H. Chalton Bradshaw, A.R.I.B.A. The last is a circular pavilion, the others taking the form of the triumphal arch with the provision of extensive surfaces for the inscription of names by means of vaulted passages.

The British Dominions.—With one exception religious architecture in the oversea dominions of the British empire cannot be said to show any very interesting modern developments. The noteworthy exception is Africa, chiefly through the initiative of Sir Herbert Baker A.R.A., whose cathedrals of Cape Town, Pretoria and Salisbury, Rhodesia, and other churches, show a most interesting adaptation to local materials and conditions, working out, at Pretoria and Salisbury, as a spacious Romanesque-Byzantine type of building, with the exclusion of light except that from comparatively small clerestorey windows. Among works in memorial architecture produced by or for the dominions must be named the "All India" war memorial, Delhi, in the form of a triumphal arch, by Sir Edwin Lutyens R.A.; the South African war memorial, Delville wood, France, by Sir Herbert Baker A.R.A.; and the Australian war memorial, Villers-Bretonneux, France, by William Lucas. The national war memorial for New Zealand is to take the form of an art gallery and museum, with a campanile and a hall of memories. In the mandatory country of Palestine there is the Jerusalem war cemetery, by Sir John Burnet R.A.

The Continent of Europe.—During the last 50 years, religious and memorial architecture all over the world has been moulded by the same influences: a less dogmatic attitude in religion and science alike, a decline in the social authority of the churches, a growth of the democratic spirit, and a progressive mechanization of labour accompanied by the discovery of new materials and methods of construction.

In France the modern period may be said to open with the basilica of the Sacré Coeur, Paris, designed by Abadie and begun in 1875. Standing on the summit of the Butte Montmartre, it forms a conspicuous object in the northern approach to Paris, and closes impressively the vistas of streets ascending from the main boulevards. Romanesque-Byzantine in style, the Sacré Coeur represents the first important break with the Renaissance tradition in France. Otherwise recent religious architecture in France is remarkable chiefly for daring experiments in reinforced concrete. The best known examples are the churches of St. Denis, Paris, Notre Dame, Raincy, and St. Thérèse, Montmagny, by the brothers Auguste and Gustave Perret, in which an attempt has been made to work out forms proceeding logically from the material itself, used constructively, with very slender internal supports, and an elaborate tracery—or rather trellis—of concrete at the windows. In the Byzantine church at Vincennes, by J. Marast, which is faced externally with brick, the vaulting is carried out with deep concrete ribs, dividing the roof into panels, and dispensing with intermediate supports. Other interesting examples of religious architecture in France are the church of St. François, St. Etienne, entirely of reinforced concrete, the columns being supported by screw-jacks to allow compensation for movements caused by mining operations below, and the tower of St. Louis, Villemomble, by Paul Tournon, with sculptured decoration in concrete.

In Germany also, the chief interest is in the use of concrete, as in the churches by Prof. Dominikus Böhm at Neu-Ulm and Bischofsheim, near Mainz. In them concrete has been employed more solidly than in the French examples, with more emphasis upon the plastic mass of concrete than upon the steel supports, in a system of parabolic vaulting which, with its projecting ribs, intersecting to form complicated patterns in the roof, suggests a true translation of Gothic principles into the new material. Other recent German churches to be noted are St. Gabriel's, Munich, by O. Kurz and E. Herbert, in Byzantine-Romanesque, and the Protestant church at Ellingen, by Bestelmeyer, which is octagonal in plan, with circular galleries, and has a bulb-domed minaret or campanile.

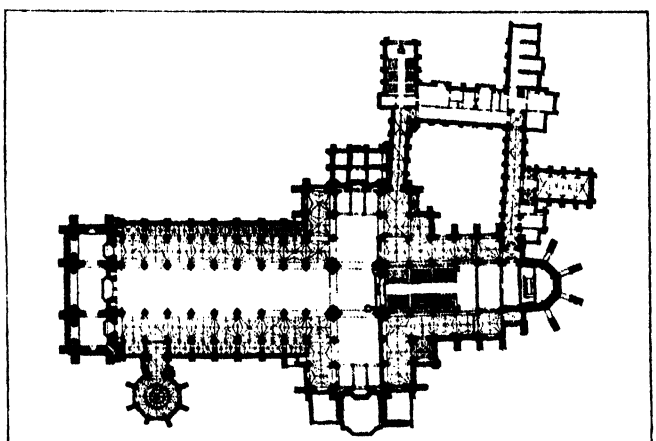
Common to all the countries of Europe is an attempt to recover a national style from the Gothic and Classic revivals, which all have experienced in some degree, embodying the principles of both without their stylish accidents; the energy of Gothic and the order and proportion of Classic. In Holland this takes the form of a development of the native brick construction, an excellent example being the church at Bussum, by Cuypers, a domed structure with round arches and vaulting ribs in brick. Other modern churches in Holland which call for mention as formal essays in brick construction are those at The Hague, by Kropholler, Bussum, by Rueter, and Utrecht, by Slothouwer.

In Scandanavia the modern impulse appears to have originated in Denmark, where there are several interesting new churches, a

stepped gable, on both tower and transepts, being a characteristic feature. The church of St. Hans Tveje, Odensee, and Grundtvig's church—associated with a housing scheme—Copenhagen, by P. V. J. Klint, are striking examples. With their tall fluted towers, ending in stepped gables, they have a curiously organ-like effect. Among smaller and simpler buildings may be named Gurre church, by Carl Brunner, the church at Aarhus, by K. Gottlieb and A. Frederiksen, and the church at Frederiksberg, by Hanning and Frederiksen.

In Sweden the national style that is emerging from the various "revivals" in response to the modern spirit appears to be —paradoxical as it may sound—a fusion of the Byzantine and the Baroque, at any rate in religious architecture, with a substitution of lean and angular forms for the full curves we associate with Baroque in the South. Two famous examples are the Saltsjöbaden church, by Ferdinand Boberg, and Högalid church, Stockholm, by Ivar Justus Tenghom. Both churches are without aisles, the Saltsjöbaden church, which contains interesting sculpture in bronze and alabaster by Carl Milles, having a polygonal apse and a single tower; while the other, which is vaulted internally, the ribs being rectangular in section, has twin towers, rather oriental in character, with bulbous domes. Masthuggs church, Gothenburg, by Sigfrid Ericson, with its massive tower and open timbered roof; Engelbrecht church, Stockholm, by L. T. Wahlman, a high-shouldered, cruciform edifice, vaulted in parabolic curves; and the small chapels by Gunnar E. Asplund and Sigurd Lerverentz, the one circular and the other like a little Corinthian temple, in the cemetery at Enskede, are other interesting buildings.

In Czechoslovakia there is a vigorous architectural revival, with such results as the Palladian basilica of St. Venceslaus, Smichov, by V. Barvitius, and the Romanesque church of Stechovice, by Kamil Hilbert.



Italy and Spain, being Catholic countries, have kept more or less on traditional lines in their religious architecture. In Italy a revival of Byzantine-Romanesque was followed by a return to Roman, of a simple and massive character, and under the present régime the Roman tradition is likely to be emphasized. Spain's most striking contribution to the modern period is the fantastic church of the Sagrada Familia, Barcelona.

As regards memorial architecture Italy provides the most important example in Europe in the memorial to Victor Emmanuel II., Rome. Designed by Count G. Sacconi and begun in 1885, it takes the form of a great loggia, with columns 48 ft. high and end pavilions, with pediments, supporting sculptured groups. In front steps ascend to a platform bearing an equestrian statue of the king. Closing a vista at the end of the Corso Umberto, it is one of the most impressive monuments ever erected to one man. All the combatant countries of Europe have their share of war memorials, taking the forms already described and generally associated with sculpture. In Sweden note must be taken of the several recent memorials, mostly in the form of fountains, by Carl Milles. Though they are the work of a sculptor they are essentially architectural in general design.

The United States.—To an extent which does not prevail in any other country religious architecture in the United States of America is affected by two conditions: the upward growth of cities, and the shading off of religious beliefs into ethical systems. The first is leading inevitably to the incorporation of places of worship in sky-scraper buildings (*see* ARCHITECTURE) of which the other floors are used for commercial purposes, *e.g.*, the Broadway Temple, New York, begun by the late Doun Barber and now being carried on by Voorhees, Gmelin and Walker; the second creates an intermediate type of building, something between the church and the lecture or concert hall, of which the Christian Science Church may be quoted as an example. Allowing for these special conditions religious architecture in America during the last 50 years has developed on very much the same lines as in England. The "colonial" version of the type of church instituted by Wren has persisted in the Congregational and Unitarian communities, Roman Catholic churches incline to the Lombard, or Romanesque-Byzantine form, and Christian Science prefers Classic; but Episcopalians and Presbyterians generally prefer Gothic. To a certain extent, the broadening and simplification of Gothic associated in England with the names of Bodley, Temple Moore and Sir Giles Gilbert Scott, have been repeated in America, particularly by the late Bertram G. Goodhue and his associates Cram and Ferguson. Churches which may be named in this connection are St. Thomas', New York City; the chapel of the U.S. Military Academy, West Point; Emmanuel church, Cleveland, O.; and the First Baptist church, Pittsburgh, all by Cram, Goodhue and Ferguson; All Saints, Peterboro, N.H., by Cram and Ferguson; church of the Holy Innocents, Brooklyn, by Helmle and Corbett; and Washington Episcopal church, originally designed by Vaughan and Bodley and carried on by Frohman, Robb and Little.

The cathedral is a comparatively recent institution in the United States, and two important examples are now in course of construction.

In 1893 Congress granted a charter for the establishment and maintenance of a cathedral and institutions of learning within the District of Columbia for the promotion of religion, education and charity. Mt. Saint Alban, 400 ft. above the Potomac river, was chosen as the site for Washington cathedral; to-day the cathedral close occupies 67½ acres. Dr. George F. Bodley, of London, and Henry Vaughan, of Boston, his pupil, both of whom have since died, were the original architects chosen and their plan was accepted in 1907; the present architects are Frohman, Robb and Little, of Boston, with Cram and Ferguson, also of Boston, as consulting architects. The cathedral will be cruciform in shape with two impressive transepts, forming the arms of the cross. The total length will be 534 ft., the width at the transepts 215 ft., the area 71,000 square feet. The central tower will be 262 ft. and the western towers 195 ft. high. The entire foundation is now structurally complete. Three chapels in the crypt, together with the vaulted connecting passages, are now open. On the main floor the apse has risen, and the choir and crossing, including the great piers to support the central tower, are approaching completion. Through the western portal, the effect promises to be a vaulted vista of more than 500 ft., through the nave, the crossing and the choir to the sanctuary. The vaulting of the nave will rise 95 ft. from the floor, and the height of the inner aisles, flanking the nave, will be 45 feet. The nave will consist of nine bays and the choir of five. The plans call for more than 800 statues, some 300 stained

FIG. 4.—PLAN OF THE WASHINGTON CATHEDRAL

glass windows and more than 1,000 sculptured bosses or keystones of the vaulted arches. The landscape work within the cathedral close combines two distinct elements: (1) that of the cathedral itself and its adjacent buildings, which is in the spirit of old world gardens; (2) that of the wooded slope of Mt. Saint Alban, preserving its natural beauty and increasing its dogwood, laurel, wild azalea and choice undergrowth. Ultimately the cathedral close will contain some 30 auxiliary buildings, harmonizing in design with the central edifice. Among these will be the chapter house, synod hall, cloisters, sacristy, choir rooms and administration

building, the dean's residence, six canons' and six minor canons' residences, 12 retired clergy residences, a library and librarian's residence, a guest house, additional buildings for St. Albans, the National Cathedral School for Boys, and the National Cathedral School for Girls, the College of Preachers and the lodges for the cathedral employees, an amphitheatre, a gymnasium and an athletic field. A stone wall with 12 gates, named after the 12 apostles, will ultimately surround the entire group.

The cathedral of St. John the Divine, on Morningside Heights, New York, when completed, will be third in area among the cathedrals of the world. Founded by the sixth bishop of New York, Bishop Horatio Potter, who obtained a charter to build it in 1873, the cathedral was originally designed by Heins and Le Farge, with a French Romanesque exterior and a Byzantine interior, the first corner stone being laid on St. John's day, 1892. Even during construction efforts were made at a greater unity of style, and the exterior of the choir was made Gothic; and when, in 1911, Dr. Ralph Adams Cram was appointed consulting architect, he reconsidered the whole design and recommended the adoption of French Gothic for both exterior and interior. In its final form St. John the Divine will be a five-aisled structure, three aisles being included within the clerestorey walls, the triforium and clerestorey being carried, not by the piers of the nave, but over those separating the inner from the outer aisles. The narrow outer aisles take the place of the chain of chapels to be found in most Continental cathedrals. There will be nine bays in the nave, with alternating large and small piers, but the roof vaulting will be in four huge bays, with internal buttressing by means of arches and wing-walls pierced by "roses" across the upper part of the inner side aisles. Owing to the narrowness of the outer aisles there will be no need for external flying buttresses. Externally St. John the Divine will have a central spire, or lantern, and twin west towers.

Other recent churches in the United States which deserve mention are Emmanuel church, Boston, Mass., by Allen and Collens; St. John's, Cambridge, Mass., by Maginnis and Walsh, and St. Bartholomew's, New York, by Goodhue, both Romanesque-Byzantine; the Renaissance Presbyterian church, Madison square, New York, by McKim, Mead and White; the Second Reformed Church, New Brunswick, N.J., by Ludlow and Peabody; and the Tabernacle Presbyterian church, Indianapolis, by J. W. C. Corbusier and R. F. Daggett. Synagogues naturally refer back to their Eastern origin, and the Byzantine Temple Tifereth Israel, Cleveland, O., by Charles R. Greco; Temple Ben Israel, Cincinnati, O., by Tietig and Lee; Temple Emanu-El, San Francisco, Cal., by Bakewell and Brown; and Isaiah temple, Chicago, Ill., by Alfred S. Abschuler, may be quoted as examples. The characteristic form and style of Christian Science churches in America is well illustrated by First Church of Christ, New York, by Carrère and Hastings, and Third Church of Christ, Park avenue, New York, by Delano and Aldrich. In California there have been some interesting experiments in concrete churches, without, however, any very determined attempt—as in France and Germany—to give formal expression to the method of construction, but rather a simplified imitation of bygone styles in the new material. Thus, the church of St. John, by Pierpont and Walter Davis, Wilshire Boulevard church, by Allison and Allison, and St. Paul's cathedral, by Johnson, Kauffman and Coate, all in Los Angeles, are Byzantine, while St. Vincent's church, by Albert C. Martin, in the same city, is in the Baroque of the Spanish mission.

Allowing for such direct imitations of the past, with a ritualistic rather than a congregational determination of plan, as is represented by the American Episcopalian Church—there is a similar phenomenon to be observed in Scotland—the general tendency in religious architecture throughout the world during the last 50 years has been towards the auditorium form of building, with allusive rather than imitative reference to the past, and particular attention to acoustical properties. This last is extremely important as a determining factor. A writer on the subject has truly said that the form of the mediaeval church was responsible for the development of the characteristic features of church choral music and intoned liturgy; it is equally true to say that, by a reversed process, the requirements of the preacher, lecturer or reader are determining the form of the modern church.

REMAGEN, a town in the Prussian Rhine Province, on the left bank of the Rhine, 12 m. above Bonn, by the railway from Cologne to Coblenz, and at the junction of the railway to Adenau. Pop. (1925) 4,775. Its Roman name was Rigomagus and many Roman remains have been found here. It passed to Prussia from the duchy of Jülich. The (Roman Catholic) parish church is remarkable for a gate dating from the 12th century. The industry of the place is almost wholly concerned with the preparation of wine, in which a large export trade is done. Just below the town, on a height overlooking the Rhine, stands the Apollinaris church, built 1839–53 on the site of a chapel formerly dedicated to St. Martin. It is a frequent place of pilgrimage from all parts of the lower Rhine. According to legend, the ship conveying the relics of the three kings and of Bishop Apollinaris from Milan to Cologne in 1164 could not be got to move away from the spot until the bones of St. Apollinaris had been interred in St. Martin's chapel.

REMAINDER, REVERSION. In the view of English law a remainder or reversion is classed either as an incorporeal hereditament or, with greater correctness, as an estate in expectancy. That is to say, it is a present interest subject to an existing estate in possession called the particular estate, which must determine before the estate in expectancy can become an estate in possession. A remainder or reversion is in strictness confined to real estate, whether legal or equitable, though a similar interest may exist in personalty. The particular estate and the remainder or reversion together make up the whole estate over which the grantor has power of disposition. Accordingly a remainder or reversion limited on an estate in fee simple is void. The difference between a remainder and a reversion, stated as simply as possible, is that the latter is that undisposed-of part of the estate which after the determination of the particular estate will fall into the possession of the original grantor or his representative, while a remainder is that part of the estate which under the same circumstances will fall into the possession of a person other than the original grantor or his representative. The subject is too technical for further treatment, for which reference must be made to legal text books.

The State laws of the United States affecting remainders will be found in Washburn, *Real Property*, ii. bk. ii. As a general rule contingent remainders have been rendered of little practical importance by enactments that they shall take effect as executory devises or shall not determine on determination of the particular estate.

REMAINDER THEOREM, a theorem of particular value in the study of polynomials and equations. If we divide

$$2x^2+3x+6 \text{ by } x-2,$$

for example, the quotient is $2x+7$ and the remainder is 20. The remainder, however, can be found by substituting 2 for x in the polynomial. This gives:

$$2\cdot 2^2+3\cdot 2+6=8+6+6=20.$$

More generally, to find the remainder arising from dividing $f(x)$ by $x-r$, substitute r for x in $f(x)$. This evidently amounts simply to evaluating $f(x)$ for some special value (r) of x. This is conveniently done by following the plan shown at the right. This work reveals not only the remainder (20) but also the coefficients ($2+7$) of the quotient ($2x+7$). When

$2+3+6$	2
$\quad 4 \quad 14$	
$2+7;\ 20$	

used for this latter purpose it is known as synthetic division. This method of dividing is very helpful in finding the roots of numerical higher equations.

REMAND, a term of English law meaning the return of a prisoner by order of a court to the custody from which he came to the court. Where trials or indictments are not concluded at a single sitting the court of trial has power to remand the accused into proper custody during any necessary adjournment. If the remand is for more than three days the order must be in writing (Indictable Offences Act 1848). Similar powers of remand or committal to prison during adjournments are given to justices in the exercise of their summary criminal jurisdiction (Summary Jurisdiction Acts 1848 and 1879).

In the case of charges against children or young persons the remand must be to a "place of detention" unless released on bail or certified unfit for such a place of detention (Children Act 1908). For this purpose homes have been established under the act.

In the United States the term is used in two senses. The first is where a prisoner is returned to custody to await the resumption of the preliminary hearing or the commencement of the trial. The second is where a cause of action is returned to the original court after the same had been transferred or appealed.

REMBRANDT (1606–1669). Rembrandt Harmens van Rijn, Dutch painter, was born in Leyden on July 15, 1606. It is only within the past 50 years that we have come to know anything of his real history. A tissue of fables formerly represented him as ignorant, boorish and avaricious. These fictions, resting on the loose assertions of Houbraken (*De Groote Schouburgh*, 1718), have been cleared away by the untiring researches of Scheltema and other Dutchmen, notably by C. Vosmaer, whose elaborate work (*Rembrandt, sa vie et ses oeuvres*, 1868, 2nd ed., 1877) is the basis of our knowledge of the man and of the chronological development of the artist.

Rembrandt was born at No. 3 Weddesteg, on the rampart at Leyden overlooking the Rhine. He was the fourth son of Gerrit Harmens van Rijn, a well-to-do miller. His parents resolved that he should enter a learned profession. With this view he was sent to the Latin School and was enrolled on May 20, 1620, as a student of the University at Leyden, but the boy soon determined to be a painter. Accordingly he was placed for three years under Swanenburch, an architectural painter trained in Italy. He then went to Peter Lastman in Amsterdam for six months, after which time he returned to Leyden where he remained from 1626—the date on his earliest picture—to 1631. During the early years of his life at Leyden, Rembrandt seems to have devoted himself entirely to studies, painting and etching the people around him, every picturesque face and form he could get hold of. Life, character, and above all light were the aims of these studies. His mother was a frequent model, and we can trace in her features the strong likeness to her son, especially in the portraits of himself at an advanced age. Eleven portraits of his father are catalogued by Hofstede de Groot. One of his sisters also frequently sat to him. Hofstede de Groot catalogues also 62 existing portraits of himself, most of them painted in youth and in old age.

Rembrandt's earliest pictures were painted at Leyden, from 1627 to 1631. They are chiefly paintings of single figures, as "St. Paul in Prison" and "St. Jerome"; but now and then compositions of several, as "Samson in Prison" and "Presentation in the Temple." The prevailing tone of all these pictures is a greenish grey, the effect being somewhat cold and heavy. The gallery at Cassel gives us a typical example of his studies of the heads of old men, firm in workmanship and full of detail, the effects of light and shade being carefully thought out. His work was now attracting the attention of lovers of art in the great city of Amsterdam; and, urged by their calls, he removed about 1631 to live and die there. At one bound he leaped into the position of the first portrait painter of the city, and received numerous commissions. During the early years of his residence there are many portraits from his hand, firm and solid in manner and staid in expression. The excellent painter Thomas de Keyser was then in the height of his power, and his influence is to be traced in some of Rembrandt's smaller portraits. Pupils also now flocked to his house in the Bloemgracht, among them Gerard Douw, who was nearly of his own age. The first important work executed by Rembrandt in Amsterdam is "Simeon in the Temple," of The Hague museum, a fine early example of his treatment of light and shade and of his subtle colour. The concentrated light falls on the principal figures while the background is full of mystery. The surface is smooth and enamel-like; the action of light on the mantle of Simeon shows how soon he had felt the magical effect of the play of colour. In the life-sized "Lesson in Anatomy" of 1632 we have the first of the great portrait subjects—Tulp the anatomist, the early friend of Rembrandt, discoursing to his seven associates, who are ranged with eager heads round the foreshortened body. The subject had been treated in former years by the Mierevelts, A. Pietersen and others, for the Hall of the Surgeons. But it was reserved for Rembrandt to make it a great picture by the grouping of the expressive portraits and by the completeness of the conception. The colour is quiet and the handling of the brush timid and precise, while the light and shade are somewhat harsh and abrupt. But it is a marvellous picture for a young man of twenty-five, and it is generally accepted as marking a new departure in the career of the painter.

In recent times the number of pictures painted by Rembrandt has been variously estimated. Smith, in his *Catalogue Raisonné* (1836) lists 614 pictures; Bode's *Catalogue* (Paris, 1897, *seq.*) lists some 550; Wurzbach's *Lexicon* (1910) has about 500; Hofstede de Groot's *Catalogue* (1916) has 988 numbers; and recently J. C. Van Dyke (*Rembrandt and his School*, New York, 1923) has reduced the number of undoubtedly genuine examples painted by the master's own hand to 48. It is impossible here to notice more than the prominent works. Besides the Pellicorne family portraits of 1632, now in the Wallace collection, we have the caligraphist Coppenol of the Cassel gallery, interesting in the first place as an early example of Rembrandt's method of giving permanent interest to a portrait by converting it into a picture. He invests it with a sense of life by a momentary expression as Coppenol raises his head towards the spectator while he is mending a quill. The same motive is to be found in the "Shipbuilder," 1633 (Buckingham Palace), who looks up from his work with a sense of interruption at the approach of his wife. Coppenol was painted and etched by the artist. The two small pictures of "The Philosopher" of the Louvre date from 1633, delicate in execution and full of mysterious effect.

In 1634 Rembrandt married Saskia van Uylenborch, a beautiful, fair-haired Frisian maiden of good connections. Till her death in 1642 she was the centre of his life and art. Saskia brought him a marriage portion of 40,000 guilders. She bore him four children, Rumbartus and two girls, successively named Cornelia after his mother, all of whom died in infancy, and Titus, named after Titia, a sister of Saskia. We have several noble portraits of Saskia, a good type of the beauty of Holland, all painted with the utmost love and care, at Cassel (1633), at Dresden (1641), and a posthumous one (1643) at Berlin.

One of Rembrandt's greatest portraits of 1634 is the superb full-length of Martin Daey, which, with that of Madame Daey, painted according to Vosmaer some years later, formed one of the ornaments of the Van Loon collection at Amsterdam. Both now belong to Baron Gustave de Rothschild. From the firm detailed execution of this portrait one turns with wonder to the broader handling of the "Old Woman" (Françoise van Wasserhoven), aged 83, in the National Gallery, of the same year, remarkable for the effect of reflected light and still more for the sympathetic rendering of character.

The life of Samson supplied many subjects in these early days. The "Samson Menacing his Father-in-Law" is forced and violent in its action. One of the prominent examples of Rembrandt's work is the "Marriage of Samson," of the Dresden gallery, painted in 1638. Here Rembrandt gives the rein to his imagination and makes the scene live before us. Except the bride (Saskia), who sits calm and grand on a dais in the centre of the feast, with the full light again playing on her flowing locks and wealth of jewels, all is animated and full of bustle. Samson, evi-

dently a Rembrandt of fantasy, leans over a chair propounding his riddle to the Philistine lords. In execution it is a great advance on former subject pictures; it is bolder in manner, and we have here signs of his approaching love of warmer tones.

The story of Susannah also occupied him in these early years, and he returned to the subject in 1641 and 1653. "The Bather" of the National Gallery may be another interpretation of the same theme. In all of these pictures the woman is coarse in type and lumpy in form, though the modelling is soft and round, the effect which Rembrandt always strove to gain. Beauty of form was outside his art. But the so-called "Danae" (1636) at Leningrad is a sufficient reply to those who deny his ability ever to appreciate the beauty of the nude female form. It glows with colour and life, and the blood seems to pulsate under the warm skin. In the picturesque story of Tobit Rembrandt found much to interest him, as we see in the beautiful small picture of the d'Arenberg Collection at Brussels. Sight is being restored to the aged Tobias, while with infinite tenderness his wife holds the old man's hand caressingly. In the Berlin gallery he paints the anxiety of the parents as they wait for the return of their son. In 1637 he painted the fine picture now in the Louvre of the "Flight of the Angel." Reverence and awe are shown in every attitude of the Tobit family. A similar lofty treatment is to be found in the "Christ as the Gardener," appearing to Mary, of 1638 (Buckingham Palace).

We have now arrived at the year 1640, the threshold of his second manner, which extended to 1654, the middle age of Rembrandt. During the latter part of the previous decade we find the shadows more transparent and the blending of light and shade more perfect. There is a growing power in every part of his art. The coldness of his first manner had disappeared, and the tones were gradually changing into golden-brown. He had attained to a truer, calmer form of dramatic expression, of which the "Manoah" of Dresden is a good example (1641). The portraits painted "to order" became more rare about this time, and those which we have are chiefly friends of his circle, such as the "Mennonite Preacher" (C. C. Ansloo) and the "Gilder," a fine example of his golden tone, in the Havemeyer collection, New York. His own splendid portrait (1640) in the National Gallery illustrates the change in his work. It describes the man well—strong and robust, with powerful head, firm and compressed lips and determined chin, with heavy eyebrows, separated by a deep vertical furrow, and with eyes of keen penetrating glance—altogether a self-reliant man. He has now many friends and pupils, and numerous commissions, even from the stadtholder; he has bought a large house in the Breedstraat, in which during the next 16 years of his life he gathers his large collection of paintings, engravings, armour and costume which figure afterwards in his inventory. His taste was wide and his purchases large, for he was joint owner with picture-dealers of paintings by Giorgione and Palma Vecchio, while for a high-priced Marcantonio Raimondi print he gave in exchange a fine impression of his "Christ Healing the Sick," which has since been known as the "Hundred Guilder Print." The stadtholder was not a prompt payer, and an interesting correspondence took place between Rembrandt and Constantin Huygens, the poet and secretary of the prince. The Rembrandt letters which have come down to us are few, and these are therefore of importance. Rembrandt puts a high value on the picture, which he says had been painted "with much care and zeal," but he is willing to take what the prince thinks proper; while to Huygens he sends a large picture as a present for his trouble in carrying through the business. There is here no sign of the grasping greed with which he has been charged, while his unselfish conduct is seen in the settlement of the family affairs at the death of his mother in 1640.

The year 1642 is remarkable for the great picture formerly known as the "Night Watch," but now more correctly as the "Sortie of the Banning Cock Company," in which 29 life-sized civic guards are introduced issuing pell-mell from their clubhouse. Such gilds of arquebusiers had been painted admirably before by Ravesteyn and notably by Frans Hals, but Rembrandt determined to throw life and animation into the scene. The dominant colour is the citron yellow uniform of the lieutenant, wearing a blue sash, while a Titian-like red dress of a musketeer, the black velvet dress of the captain, and the varied green of the girl and drummer, all produce a rich and harmonious effect. The background has become dark and heavy, and the scutcheon on which the names are painted is scarcely to be seen.

But this year of great achievement was also the year of his great loss, for Saskia died in 1642, leaving Rembrandt her sole trustee for her son Titus, but with full use of the money till he should marry again or till the marriage of Titus. The words of the will express her confidence in her husband. With her death his life was changed. There is a pathetic sadness in his pictures of the Holy Family—a favourite subject at this period of his life. All of these he treats with the naïve simplicity of Reformed Holland, giving us the real carpenter's shop and the mother watching over the Infant reverently and lovingly, with a fine union of realism and idealism.

The street in which he lived was full of Dutch and Portuguese Jews, and many a Jewish rabbi sat to him. He accepted or invented their turbans and local dress as characteristic of the people. But in his religious pictures it is not the costume we look at; what strikes us is the profound perception of the sentiment of the story, making them true to all time and independent of local circumstance. A notable example of this feeling is to be found in the "Woman Taken in Adultery" of the National Gallery, painted in 1644 in the manner of the "Simeon" of The Hague. It commands our attention from the grand conception of the painter who has invested Christ with majestic dignity. A similar lofty ideal is to be found in his various renderings of the "Pilgrims at Emmaus," notably in the Louvre picture of 1648. From the same year we have the "Good Samaritan" of the Louvre, the story of which is told with intense pathos. The helpless suffering of the wounded man, the curiosity of the boy on tiptoe, the excited faces at the upper window, are all conveyed with masterly skill. In these last two pictures we find a broader touch and freer handling, while the tones pass into a dull yellow and brown with a predilection for a note of deep rich red.

Rembrandt touched no side of art without setting his mark on it, whether in still life, as in his dead birds or the "Slaughtered Ox" of the Louvre (with its repetitions at Glasgow and Budapest), or in his drawings of elephants and lions, all of which are instinct with life. But at this period of his career we come upon a branch of his art on which he left, both in etching and in painting, the stamp of his genius, viz., landscape. Roeland Roghman, but ten years his senior, evidently influenced his style, for the resemblance between their works is so great that, as at Cassel, there has been confusion of authorship. Hercules Seghers also was much appreciated by Rembrandt, for at his sale eight pictures by this master figure in the inventory, and Vosmaer discovered that Rembrandt had worked on a plate by Seghers and had added figures to an etched "Flight into Egypt." The earliest pure landscape known to us from Rembrandt's hand is that at the Rijks museum (1637–38), followed in the latter year by those at Brunswick, Boston (U.S.A.) and "The River Scene," formerly in the collection of Marcus Kapfel, Berlin. Better known is the "Winter Scene" of Cassel (1646), silvery and delicate. As a rule in his painted landscape he aims at grandeur and poetical effect, as in the "Repose of the Holy Family" of 1647 in the National gallery, Dublin, a moonlight effect, clear even in the shadows. The "Canal" in the Rijks museum, Amsterdam, is also conceived in this spirit. A similar poetical vein runs through the "Landscape with Ruins" of Cassel, in which the beams of the setting sun strike on the ruins while the valley is sunk in the shades of approaching night. More powerful still is the weird effect of the "Windmill," with its glow of light and darkening shadows. In all these pictures light with its magical influences is the theme of the poet-painter. From the number of landscapes by himself in the inventory of his sale, it would appear that these grand works were not appreciated by his contemporaries. The last of the landscape series dates from 1655 or 1656, the close of the middle age or manhood of Rembrandt, a period of splendid power. In the "Joseph Accused by Potiphar's Wife" of 1655 we have great dramatic vigour and

perfect mastery of expression, while the brilliant colour and glowing effect of light and shade attest his strength. To this period also belongs the great portrait of himself in the Fitzwilliam museum at Cambridge.

But evil days were at hand. The long-continued wars and civil troubles had worn out the country, and money was scarce; and we find Rembrandt borrowing considerable sums of money on the security of his house. Then, in this year of 1654, we find him involved in the scandal of having a child by his servant Hendrickje Jagers or Stoffels, as appears by the books of the Reformed Church at Amsterdam. He recognized the child and gave it the name of Cornelia, after his mother, but there is no proof that he married Hendrickje, who seems to have continued to live with him, for we find her claiming a chest as her property at his sale in 1658.

The beautiful portrait of the "Lady" in the Salon Carré of the Louvre and the "Venus and Cupid" of the same gallery may represent Hendrickje and her child. Both pictures belong to this date, and by their treatment are removed from the category of Rembrandt's usual portraits. But if this is conjecture, we get nearer to fact when we look at the picture to which tradition has attached the name of "Rembrandt's Mistress," now in the Edinburgh National Gallery. At a glance one can see that it is not the mere head of a model, as she lies in bed raising herself to put aside a curtain. In 1654 he painted the famous "Portrait of Jan Six," the future burgomaster, consummate in its ease and character, as Six descends the steps of his house drawing on his glove. The connection between Rembrandt and the great family of Six was long and close. In 1641 the mother of Six, Anna Wymer, had been painted with consummate skill by Rembrandt, who also executed in 1647 the beautiful etching of Six standing by a window reading his tragedy of *Medea*, afterwards illustrated by Rembrandt. Now he paints his portrait in the prime of manhood. In 1656 Rembrandt's financial affairs became more involved, and the Orphan's Chamber transferred the house and ground to Titus, though Rembrandt was still allowed to take charge of Saskia's estate. Nothing, however, could avert the ruin of the painter, who was declared bankrupt in July 1656, an inventory of all his property being ordered by the Insolvency Chamber. The first sale took place in 1657 in the Keizerskroon hotel; and the second in 1658, when the larger part of the etchings and drawings were disposed of—"collected by Rembrandt himself with much love and care," says the catalogue. The sum realized, under 5,000 guilders, was but a fraction of their value. Driven thus from his house, stripped of everything he possessed, even to his table linen, Rembrandt took a modest lodging in the Keizerskroon hostelry (the amounts of his bills are on record), apparently without friends and thrown entirely on himself.

But this dark year of 1656 stands out prominently as one in which some of his greatest works were produced, as, for example, "Jacob blessing the Sons of Joseph" of the Cassel Gallery, and "John the Baptist Preaching" of the Berlin gallery, though this picture is sometimes ascribed to an earlier period of about 1635. Instead of the brilliancy of 1654 we have for two or three years a preference for dull yellows, reds and greys, with a certain uniformity of tone. The handling is broad and rapid. There is less caressing of colour for its own sake, even less straining after vigorous effect of light and shade. To the same year belongs the "Lesson in Anatomy of Johann Deyman," in the museum at Amsterdam. The subject is similar to the great Tulp of 1632, but his manner and power of colour had advanced so much that Sir Joshua Reynolds, on his visit to Holland in 1781, was reminded by it of Michelangelo and Titian. The same period gives us the "Adoration of the Magi" of Buckingham Palace.

After the sale of the house in the Breedstraat, Rembrandt retired to the Rosengracht, an obscure quarter at the west end of the city. We are now drawing to the splendid close of his career in his third manner, in which his touch became broader, his impasto more solid and his knowledge more complete. We may mention the "Old Man with the Grey Beard" of the National Gallery (1657) leading up to the great portraits of the "Syndics of the Cloth Hall" of 1661.

In his old age Rembrandt continued to paint his own portrait as assiduously as in his youthful days. Fine examples are in the Louvre, in the National Gallery, London, and in the Frick collection, New York. All show the same self-reliant expression, though broken down by age and the cares of a hard life.

About the year 1668, Rembrandt painted the (so-called) "Jewish Bride" of the Rijks museum in Amsterdam, and the "Family Group" of Brunswick, the last and perhaps the most brilliant works of his life, bold and rapid in execution and marvellous in the subtle mixture and play of colours in which he seems to revel.

In 1668 Titus, the only son of Rembrandt, died, leaving one child, and on Oct. 4, 1669, the great painter himself passed away, leaving two children, and was buried in the Wester Kerk. He had outlived his popularity, for his manner of painting was no longer in favour with a people who preferred the smooth trivialities of Van der Werff and the younger Mieris.

We must give but a short notice of Rembrandt's achievements in etching. Here he stands out by universal confession as first excelling by his unrivalled technical skill, his mastery of expression and the lofty conceptions of many of his great pieces, as in the "Death of the Virgin," the "Christ Preaching," the "Christ Healing the Sick" (the "Hundred Guilder Print"), the "Presentation to the People," the "Crucifixion" and others. So great is his skill simply as an etcher that one is apt to overlook the nobleness of the etcher's ideas, and this tendency has been doubtless confirmed by the enormous difference in money value between "states" of the same plate, rarity giving in many cases a factitious worth in the eyes of collectors. The points of difference between these states arise from the additions and changes made by Rembrandt on the plate; and the prints taken off by him have been subjected to the closest inspection by Bartsch, Gersaint, Wilson, Daulby, De Claussin, C. Blanc, Seymour Haden, Middleton, Dutuit, Rovinski, Singer, Hind and lately by J. C. Van Dyke and Coppier, who have described them, and to whom the reader is referred. The classification of Rembrandt's etchings adopted till lately was according to the subject, as biblical, portrait, landscape, and so on; until Vosmaer attempted the more scientific and interesting line of chronology. This method has been developed by Sir F. Seymour Haden and Middleton.

The great period of his etching lies between 1639 and 1661, after which the old painter seems to have renounced the needle. In these 20 years were produced his greatest works in portraiture, landscape and Bible story. They bear the impress of the genius of the man. Rembrandt's drawings are done almost exclusively in pen and wash, though he used red and black chalk sometimes in his early period. His line, apparently haphazard, is extremely suggestive, expressive and sure, and by a few strokes of the pen he suggests scenes full of life and feeling. The publication *Original Drawings by Rembrandt* (1888–1906) was issued in three series of eight volumes. The first series, with 200 drawings edited by F. Lippmann with the help of Bode, Colvin, Seymour Haden and Heseltine, contains the best drawings. The following two series completed by Hofstede de Groot contain many doubtful pieces. Recently attempts have been made to distinguish the master's work from that of his pupils by W. R. Valentiner and by J. C. Van Dyke (the *Rembrandt Drawings and Etchings*, New York, 1927). But agreement has not been reached.

For bibliography and general *see:* C. Vosmaer, *Rembrandt* (2nd ed., The Hague, 1877); W. Bode, *Studien zur Geschichte der Holländischen Malerei* (Brunswick, 1883); E. Michel, *Rembrandt* (Paris, 1893; London, 1906); W. Bode and C. H. de Groot, *Rembrandt* complete work 8 vols. (1897–1906); W. Bode, *Rembrandt und seine Zeitgenossen* (Leipzig, 1906); C. H. de Groot, *Die Urkunden* (The Hague, 1905); J. Baldwin Brown, *Rembrandt* (1907); W. R. Valentiner, *Rembrandt und seine Umgebung* (Strasbourg, 1905).

For reproductions of Rembrandt's work *see:* the monumental folios compiled by Dr. Bode, in smaller form the volume on Rembrandt in the series *Klassiker der Kunst* (3rd ed. by Dr. Valentiner, Stuttgart, 1908); with a supplementary volume of recently discovered Rembrandts issued in 1921; and the volumes of Rembrandt's etchings compiled by H. W. Singer (1906) and of Rembrandt's drawings compiled by W. R. Valentiner (1924–) in the same series; and the volumes of Rembrandt's etchings arranged by A. M. Hind (1912 and 1923).

For appreciations of Rembrandt's work *see* E. Fromentin, *Maîtres d'autrefois* (1904); D. Langbehn, *Rembrandt als Erzieher* (Leipzig, 1890); P. G. Hamerton, *Rembrandt's Etchings* (1894); W. Weisbach, *Rembrandt* (1926). (J. F. W.)

REMEMBRANCER, the name of certain officials who compiled the memoranda rolls and prepared the business for the barons of the exchequer, and so "reminded" them of the matter with which they must deal. There were at one time three clerks of the remembrance, styled king's remembrancer, lord treasurer's remembrancer and remembrancer of first-fruits. The latter two offices have become extinct. At the present moment (1929) the King's remembrancer is required to be a master of the court of exchequer, and by the Supreme Court of Judicature (Officers) Act, 1879, he is a master of the supreme court. The office is usually filled by the senior master. The king's remembrancer still assists at certain ceremonial functions. His duties are set out in the *Second Report of the Legal Departments Commission* (1874).

"Remembrancer" is also the title of an official of the corporation of the City of London, whose principal duty is to represent that body before parliamentary committees and at council and treasury boards.

REMIGIUS, ST. (*c.* 437–533), bishop of Reims and the friend of Clovis, whom he converted to Christianity. According to Gregory of Tours, 3,000 Franks were baptized with Clovis by Remigius on Christmas Day, 496, after the defeat of the Alamanni. A good many fictions grew up around his name, *e.g.*, that he anointed Clovis with oil from the sacred ampulla, and that Pope Hormisdas had recognized him as primate of France. The *Commentary on the Pauline Epistles* (ed. Villalpandus, 1699) is not his work, but that of Remigius of Auxerre.

For authorities *see* H. Jadart, *Bibliographie des ouvrages conc. la vie et le culte de S. Remi* . . . (Reims, 1891).

REMINGTON, FREDERICK (1861–1909), American artist, was born at Canton (N.Y.), on Oct. 4, 1861. He was a pupil of the Yale Art School, and of the Art Students' League, New York, and became known as an illustrator, painter and sculptor. Having spent much time in the West, where he went for his health, and having been with the United States troops in actual warfare, he made a specialty of rendering the North American Indian and the United States soldier as seen on the western plains. In the Spanish-American War he was with the army under General Shafter as war correspondent. He died Dec. 26, 1909, near Ridgefield (Conn.). His statuettes of soldiers, Indians, cowboys and trappers are full of character, while his paintings have been largely reproduced. He wrote several volumes of stories, including *Pony Tracks* (1895), *Crooked Trails* (1898), *Sundown Leflare* (1899), and *John Ermine of the Yellowstone* (1902).

REMIREMONT, a town of eastern France, in the department of Vosges, 17 m. S.S.E. of Épinal by rail, on the Moselle, below its confluence with the Moselotte. Pop. (1926) 8,552. Remiremont (*Romarici Mons*) is named after St. Romaric, a companion of St. Columban of Luxeuil, who in the 7th century founded a monastery and a convent on the hills above the present town. In 910 an invasion of the Hungarians drove the nuns to Remiremont, which had grown round a villa of the Frankish kings, and in the 11th century they settled there. Enriched by dukes of Lorraine, kings of France and emperors of Germany, the ladies of Remiremont attained great power. The abbess was a princess of the empire, and received consecration at the hands of the pope. The fifty canonesses were selected from the nobility. On Whit-Monday the neighbouring parishes paid homage to the chapter in a ceremony called the "Kyrioles"; and on their accession the dukes of Lorraine, the immediate suzerains of the abbey, had to come to Remiremont to swear to continue their protection. The "War of the Scutcheons" (Panonceaux) in 1566 between the duke and the abbess ended in favour of the duke, and terminated the abbess's power. The monastery and nunnery were both suppressed in the Revolution. Remiremont is surrounded by forest-clad mountains. The 13th cent. abbey church has a crypt of the 11th century. The abbatial residence (which now contains the *mairie*, the court-house and the public library) has been twice rebuilt in the original plan in modern times. Some of the houses of the canonesses (17th and 18th centuries) remain. Remiremont has a board of trade-arbitrators and a chamber of arts and manufactures. Its industries include cotton-spinning and weaving, the manufacture of embroidery, iron and copper founding and the manufacture of brushes.

REMIZOV, ALEXIS (1877–), Russian novelist, was born June 24, 1877, in Moscow and brought up amid factory surroundings and in the strict observance of Orthodox Church rites, with frequent pilgrimages to monasteries. He thus gained an intimate knowledge of national habits, monastic life and old religious legends. He studied natural science and economics at Moscow University, took part in revolutionary activities, and was imprisoned and spent years of exile in Vologda. He subsequently went to live in Paris. The influences of his varying surroundings contributed to the formation of his unique fantastic personality, uniting the whimsical mischievousness of some fairy-tale sprite with a deep spirit of pity. His literary life dates from 1902; from that time until 1920 he published 36 volumes of fiction: novels, tales, short stories and fairy-tales, miracle plays, etc.

The most remarkable of Remizov's novels are *The Pond* (1905), a powerful and gloomy picture of vulgarity, vice and crime among the Moscow bourgeoisie and the monasteries; *The Clock* (1908, Eng. trans. 1924); *The Fifth Pestilence*, two stories of provincial life (Eng. trans. by A. Brown 1927); *The Sisters of the Cross* (1910), a novel of St. Petersburg life; also *The Cockerel* and stories relating to the revolution of 1905, and several plays.

REMONSTRANTS, the name given to those Dutch Protestants who, after the death of Arminius (*q.v.*), maintained the views associated with his name, and in 1610 presented to the states of Holland and Friesland a "remonstrance" in five articles formulating their points of departure from stricter Calvinism. These were: (1) that the divine decree of predestination is conditional, not absolute; (2) that the Atonement is in intention universal; (3) that man cannot of himself exercise a saving faith; (4) that though the grace of God is a necessary condition of human effort it does not act irresistibly in man; (5) that believers are able to resist sin but are not beyond the possibility of falling from grace. The Remonstrants were assailed both by personal enemies and by the political weapons of Maurice of Orange, who executed and imprisoned their leaders for holding republican views. In 1618–19 the synod of Dort (*see* DORT, SYNOD OF), from which the thirteen Arminian pastors headed by Simon Episcopius (*q.v.*) were shut out, established the victory of the Calvinist school. The judgment of the synod was enforced by the deposition and in some cases the banishment of Remonstrant ministers; but the government soon became convinced that their party was not dangerous to the state, and in 1630 they were formally allowed liberty to reside in all parts of Holland and build churches and schools. Henceforth, however, their importance was more theological than ecclesiastical; and their liberal school of theology, which naturally grew more liberal and even rationalistic, has reacted powerfully on the state church and on other Christian denominations.

REMORA or **SUCKING-FISH,** a name given to fishes of the family Echeneididae, remarkable for having the spinous dorsal fin transformed into a transversely laminated suctorial disc, placed on top of the head. There are about a dozen species from warm seas; they attach themselves to sharks, turtles, and large fish, and are transported by them, but they detach themselves and swim when searching for food.

REMPHAN (in A.V., *Rephan* in R.V.) a word found in Acts vii. 43 ('Ρομφά, Westcott and Hort). The writer is quoting the Septuagint of Amos v. 26 ('Ραιφάν), where the Hebrew has *Kiyyûn* (כיון). This is probably a mistake for *Kewan*, the Babylonian name for the planet Saturn. The Greek form may be an error of the transliterator.

REMSCHEID, a town in the Prussian Rhine Province, 6 m. by rail S. of Barmen and 20 m. N.E. of Cologne. Pop. (1925) 77,257. Remscheid is a centre of the hardware industry, and large quantities of tools, scythes, drills and other small articles in iron, steel and brass are made for export to all parts.

REMSEN, IRA (1846–1927), American chemist, was born in New York city on Feb. 10, 1846, and educated at the College

of the City of New York (B.A., 1865), College of Physicians and Surgeons (Columbia—M.D., 1867) and at the Universities of Munich and Göttingen (Ph.D., 1870). He spent the two years 1870–72 at the University of Tübingen as assistant to Fittig and here began the investigations into pure chemistry upon which his later fame was chiefly based. He was professor of chemistry at Williams college in 1872–76 and in 1876 was one of the original faculty of the new Johns Hopkins university. Here he was professor of chemistry 1876–1913, director of the chemical laboratory 1876–1908, secretary of the Academic Council 1881–1901 and president of the university 1901–1913. He was president emeritus and professor emeritus 1913–1927, during which time he travelled widely and worked on government pure food commissions. He brought to Johns Hopkins many of the German laboratory methods and as a teacher he soon became famous. A long series of students trained in intimate association with him became widely scattered and influential. He founded the *American Chemical Journal* in 1879 and continued to edit it almost to the time of his death. In it most of his scientific papers were published. In the first volume he described the preparation and properties of a new compound, subsequently to become widely known as saccharine, which he and a pupil discovered. Another long series of studies led to the discovery and enunciation of Remsen's law. He also became widely known for his series of text-books, *Principles of Theoretical Chemistry* (1876) passing through five editions and being translated into German, Russian and Italian. Others of like popularity were *An Introduction to the Study of the Compounds of Carbon* (1885; 5th rev., 1922); *Elements of Chemistry* (1888); *Inorganic Chemistry* (1889); *A College Text-book of Chemistry* (1908). Remsen died at Carmel, Cal., on Mar. 5, 1927.

See B. Harrow, *Eminent Chemists of Our Time* (1920); "Impressions of Ira Remsen," in *Johns Hopkins Alumni Magazine,* vol. xvi. pp. 215–226 (1928); "Ira Remsen" in *Science,* N.S. vol. lxvi. (1927), pp. 243–246.

RÉMUSAT, CHARLES FRANÇOIS MARIE, COMTE DE (1797–1875), French politician and man of letters, was born in Paris on March 13, 1797. He was called to the bar, and became an active journalist. He signed the journalists' protest against the Ordinances of July 1830, and in October was elected deputy for Haute Garonne. He then ranked himself with the *doctrinaires,* and supported measures of restriction on popular liberty.

Rémusat held office under Thiers in the reign of Louis Philippe. He took no part in politics under the Empire until 1869. In Aug. 1871 he succeeded Favre as minister of foreign affairs. He died in Paris on Jan. 6, 1875.

His works include: *Abélard* (2 vols., 1845); *Saint Anselme de Cantorbéry* (1854); *L'Angleterre au XVIIIème siècle* in 1856 (2nd ed. enlarged, 1865); *Bacon, sa vie, son temps,* etc. (1858); *Channing, sa vie et ses oeuvres* (1862); *John Wesley* (1870); *Lord Herbert de Cherbury* (1874) *Histoire de la philosophie en Angleterre depuis Bacon jusqu'à Locke* (1875).

RÉMUSAT, JEAN PIERRE ABEL (1788–1832), French Chinese scholar, was born in Paris on Sept. 5, 1788. He was educated for the medical profession, but a Chinese herbal in the collection of the Abbé Tersan led him to study Chinese. His *Essai sur la langue et la littérature chinoises* (1811) won him the patronage of Silvestre de Sacy, and in 1814 he was appointed to the chair of Chinese founded in that year at the Collège de France. His contributions from Chinese sources to the history of the Tatar nations claims special notice. Rémusat became an editor of the *Journal des savants* in 1818, and founder and first secretary of the Paris Asiatic Society in 1822; he also held various Government appointments. He died at Paris on June 4, 1832. A list of his works is given in Quérard's *France littéraire* s.v. Rémusat.

RENAISSANCE, THE. The "Renaissance" or "Renascence" is a term used to indicate a well-known but indefinite space of time and a certain phase in the development of Europe. On the one hand it denotes the transition from that period of history which we call the middle ages (*q.v.*) to that which we call modern. On the other hand it implies those changes in the intellectual and moral attitude of the Western nations by which the transition was characterized. If we insist upon the literal and etymological meaning of the word, the Renaissance was a re-birth; and it is needful to inquire of what it was the re-birth. The metaphor of Renaissance may signify the entrance of the European nations upon a fresh stage of vital energy in general, implying a fuller consciousness and a freer exercise of faculties than had belonged to the mediaeval period. Or it may mean the resuscitation of simply intellectual activities, stimulated by the revival of antique learning and its application to the arts and literatures of modern peoples. Upon our choice between these two interpretations of the word depend important differences in any treatment of the subject. The former has the disadvantage of making it difficult to separate the Renaissance from other historical phases—the Reformation for example—with which it ought not to be confounded. The latter has the merit of assigning a specific name to a limited series of events and group of facts, which can be distinguished for the purpose of analysis from other events and facts with which they are intimately but not indissolubly connected. In other words, the one definition of Renaissance makes it denote the whole change which came over Europe at the close of the middle ages. The other confines it to what was known by our ancestors as the Revival of Learning. Yet, when we concentrate attention on the recovery of antique culture, we become aware that this was only one phenomenon or symptom of a far wider and more comprehensive alteration in the conditions of the European races. We find it needful to retain both terms, Renaissance and Revival of Learning, and to show the relations between the series of events and facts which they severally imply. The Revival of Learning must be regarded as a function of that vital energy, an organ of that mental evolution, which brought into existence the modern world, with its new conceptions of philosophy and religion, its reawakened arts and sciences, its firmer grasp on the realities of human nature and the world, its manifold inventions and discoveries, its altered political systems, its expansive and progressive forces. Important as the Revival of Learning undoubtedly was, there are essential factors in the complex called the Renaissance with which it can but remotely be connected. When we analyse the whole group of phenomena which have to be considered, we perceive that some of the most essential have nothing or little to do with the recovery of the classics. These are, briefly speaking, the decay of those great fabrics, church and empire, which ruled the middle ages both as ideas and as realities; the development of nationalities and languages; the enfeeblement of the feudal system throughout Europe; the invention and application of paper, the mariner's compass, gunpowder, and printing; the exploration of continents beyond the ocean; and the substitution of the Copernican for the Ptolemaic system of astronomy. Europe in fact had been prepared for a thorough-going metamorphosis before that new idea of human life and culture which the Revival of Learning brought to light had been made manifest. It had recovered from the confusion consequent upon the dissolution of the ancient Roman empire. The Teutonic tribes had been Christianized, civilized and assimilated to the previously Latinized races over whom they exercised the authority of conquerors. Comparative tranquillity and material comfort had succeeded to discord and rough living. Modern nationalities, defined as separate factors in a common system, were ready to co-operate upon the basis of European federation. The ideas of universal monarchy and of indivisible Christendom, incorporated in the Holy Roman empire and the Roman Church, had so far lost their hold that scope was offered for the introduction of new theories both of state and church which would have seemed visionary or impious to the mediaeval mind. It is, therefore, obvious that some term, wider than Revival of Learning, descriptive of the change which began to pass over Europe in the 14th and 15th centuries, has to be adopted. That of Renaissance, Rinascimento, or Renascence is sufficient for the purpose, though we have to guard against the tyranny of what is after all a metaphor. We must not suffer it to lead us into rhetoric about the deadness and the darkness of the middle ages, or hamper our inquiry with preconceived assumptions that the re-birth in question was in any true sense a return to the irrecoverable pagan past. Nor must we imagine that there was any abrupt break with the middle ages. On the contrary, the Renaissance was rather the last stage of the middle ages emerging

from ecclesiastical and feudal despotism, developing what was original in mediaeval ideas by the light of classic arts and letters, holding in itself the promise of the modern world. It was, therefore, a period and a process of transition, fusion, preparation, tentative endeavour. And just at this point the real importance of the Revival of Learning may be indicated. That rediscovery of the classic past restored the confidence in their own faculties to men striving after spiritual freedom; revealed the continuity of history and the identity of human nature in spite of diverse creeds and different customs; held up for emulation master-works of literature, philosophy and art; provoked inquiry; encouraged criticism; shattered the narrow mental barriers imposed by mediaeval orthodoxy. Humanism[1], a word which will often recur in the ensuing paragraphs, denotes a specific bias which the forces liberated in the Renaissance took from contact with the ancient world—the particular form assumed by human self-esteem at that epoch—the ideal of life and civilization evolved by the modern nations. It indicates the endeavour of man to reconstitute himself as a free being, not as the thrall of theological despotism, and the peculiar assistance he derived in this effort from Greek and Roman literature, the *litterae humaniores,* letters leaning rather to the side of man than of divinity.

In this article the Renaissance will be considered as implying a comprehensive movement of the European intellect and will toward self-emancipation, toward reassertion of the natural rights of the reason and the senses, toward the conquest of this planet as a place of human occupation, and toward the formation of regulative theories both for states and individuals differing from those of mediaeval times. The Revival of Learning will be treated as a decisive factor in this process of evolution on a new plan. To exclude the Reformation and the Counter-Reformation wholly from the survey is impossible. These terms indicate moments in the whole process of modern history which were opposed, each to the other, and both to the Renaissance; and it is needful to bear in mind that they have, scientifically speaking, a quite separate existence. Yet, if the history of Europe in the 16th century of our era came to be written with the brevity with which we write the history of Europe in the 6th century B.C., it would be difficult at the distance of time implied by that supposition to distinguish the Italian movement of the Renaissance in its origin from the German movement of the Reformation. Both would be seen to have a common starting-point in the reaction against long dominant ideas which were becoming obsolete, and also in the excitation of faculties which had during the same period been accumulating energy.

Chronology.—The Renaissance, if we try to regard it as a period, was essentially the transition from one historical stage to another. It cannot therefore be confined within strict chronological limits. There is one date, however, which may be remembered with advantage as the starting-point in time of the Renaissance, after the departure from the middle ages had been definitely and consciously made by the Italians. This is the year 1453, when Constantinople, chosen for his capital by the first Christian emperor of Rome, fell into the hands of the Turk.[2] One of the survivals of the old world, the shadow of what had been the Eastern empire, now passed suddenly away. Almost at the same date that visionary revival of the Western empire, which had imposed for six centuries upon the imagination of mediaeval Europe, hampering Italy and impeding the consolidation of Germany, ceased to reckon among political actualities; while its more robust rival, the Roman Church, seemed likely to sink into the rank of a petty Italian principality. It was demonstrated by the destruction of the Eastern and the dotage of the Western empire and by the new papal policy which Nicholas V. inaugurated, that the old order of society was about to be superseded. Nothing remained to check those centrifugal forces in state and church which substituted a confederation of rival European Powers for the earlier ideal of universal monarchy, and separate religious constitutions for the previous Catholic unity. At the same time the new learning introduced by the earlier humanists awakened free thought, encouraged curiosity, and prepared the best minds of Europe for speculative audacities from which the schoolmen would have shrunk, and which soon expressed themselves in acts of cosmopolitan importance. If we look a little forward to the years 1492–1500, we obtain a second date of great importance. In these years the expedition of Charles VIII. to Naples opened Italy to French, Spanish and German interference. The leading nations of Europe began to compete for the prize of the peninsula, and learned meanwhile that culture which the Italians had perfected. In these years the secularization of the papacy was carried to its final point by Alexander VI., and the Reformation became inevitable. The same period was marked by the discovery of America, the exploration of the Indian seas, and the consolidation of the Spanish nationality. It also witnessed the application of printing to the diffusion of knowledge. Thus, speaking roughly, the half-century between 1450 and 1500 may be termed the culminating point of the Renaissance. The transition of the mediaeval to the modern order was now secured if not accomplished, and a rubicon had been crossed from which no retrogression to the past was possible. Looking yet a little farther to the years 1527 and 1530 a third decisive date is reached. In the first of these years happened the sack of Rome, in the second the pacification of Italy by Charles V. under a Spanish hegemony. The age of the Renaissance was now closed for the land which gave it birth. The Reformation had taken firm hold on northern Europe. The Counter-Reformation was already imminent.

[1] To the humanists themselves "humanitas" meant nothing more nor less than "culture."

[2] Most scholars now deny that the fall of Constantinople had any appreciable influence on the culture of Western Europe. For Symonds' date of 1453 they would substitute the date of the invention of printing about 1440.

THE MIDDLE AGES

It must not be imagined that so great a change as that implied by the Renaissance was accomplished without premonitory symptoms and previous endeavours. In the main we mean by it the recovery of freedom for the human spirit after a long period of bondage to oppressive ecclesiastical and political orthodoxy—a return to the liberal and practical conceptions of the world which the nations of antiquity had enjoyed, but upon a new and enlarged platform. This being so, it was inevitable that the finally successful efforts after self-emancipation should have been anticipated from time to time by strivings within the ages that are known as dark and mediaeval. It is, therefore part of the present inquiry to pass in review some of the claimants to be considered precursors to the Renaissance.

First of all must be named the Frank in whose lifetime the dual conception of universal empire and universal church, divinely appointed sacred and inviolable, began to control the order of European society. Charles the Great (Charlemagne) lent his forces to the plan of resuscitating the Roman empire at a moment when his own power made him the arbiter of Western Europe, when the papacy needed his alliance, and when the Eastern empire had passed under the usurped regency of a female. He modelled an empire, Roman in name, but essentially Teutonic, since it owed such substance as its fabric possessed to Frankish armies and the sinews of the German people. As a structure composed of divers ill-connected parts it fell to pieces at its builder's death, leaving little but the incubus of a memory, the fascination of a mighty name, to dominate the mind of mediaeval Europe. As an idea, the Empire grew in visionary power, and remained one of the chief obstacles in the way of both Italian and German national coherence. Real force was not in it, but rather in that counterpart to its unlimited pretensions, the Church which had evolved it from barbarian night, and which used her own more vital energies for undermining the rival of her creation. Charles the Great, having proclaimed himself successor of the Caesars, was obscurely ambitious of imitating the Augusti also in the sphere of letters. He caused a scheme of humanistic education to be formulated, and gave employment at his court to rhetoricians of whom Alcuin was the most considerable. But very little came of the Revival of Learning which Charles is supposed to have encouraged; and the empire he restored was accepted by the mediaeval intellect in a crude theological and vaguely mystical spirit. We should, how-

ever, here remember that the study of Roman law, which was one important precursory symptom of the Renaissance, owed much to mediaeval respect for the empire as a divine institution. This, together with the municipal Italian intolerance of the Lombard and Frankish codes, kept alive the practice and revived the science of Latin jurisprudence at an early period.

Speculation and Heresy.—Philosophy had tried to free itself from the trammels of theological orthodoxy in the hardy speculations of some schoolmen, notably of Scotus Erigena and Abelard. These innovators found, however, small support, and were defeated by opponents who used the same logical weapons with authority to back them. Nor were the rationalistic opinions of the Averroists without their value, though the Church condemned these deviators from her discipline as heretics. Such mediaeval materialists, moreover, had but feeble hold upon the substance of real knowledge. Imperfect acquaintance with authors whom they had studied in Latin translations made by Jews from Arabic commentaries on Greek texts, together with almost total ignorance of natural laws, condemned them to sterility. Like the other schiomachists of their epoch, they fought with phantoms in a visionary realm. A similar judgment may be passed upon those Paulician, Albigensian, Paterine and Epicurean dissenters from the Catholic creed who opposed the phalanxes of orthodoxy with frail imaginative weapons, and alarmed established orders in the state by the audacity of their communistic opinions. Physical science struggled into feeble life in the cells of Gerbert and Roger Bacon. But these men were accounted magicians by the vulgar; and, while the one eventually assumed the tiara, the other was incarcerated in a dungeon. The schools meanwhile resounded still to the interminable dispute upon abstractions. Are only universals real, or has each name a corresponding entity? From the midst of the Franciscans who had persecuted Roger Bacon because he presumed to know more than was consistent with human humility arose John of Parma, adopting and popularizing the mystic prophecy of Joachim of Flora. The reign of the Father is past; the reign of the Son is passing; the reign of the Spirit is at hand. Such was the formula of the Eternal Gospel, which as an unconscious forecast of the Renaissance, has attracted retrospective students by its felicity of adaptation to their historical method. Yet we must remember that this bold intuition of the abbot Joachim indicated a monastic reaction against the tyrannies and corruptions of the Church, rather than a fertile philosophical conception. The Fraticelli spiritualists, and similar sects who fed their imagination with his doctrine, expired in the flames to which Fra Dolcino Longino and Margharita were consigned. To what extent the accusations of profligate morals brought against these reforming sectarians were justified remains doubtful; and the same uncertainty rests upon the alleged iniquities of the Templars. It is only certain that at this epoch the fabric of Catholic faith was threatened with various forms of prophetic and Oriental mysticism, symptomatic of a widespread desire to grasp at something simpler, purer and less rigid than Latin theology afforded. Devoid of criticism, devoid of sound learning, devoid of a firm hold on the realities of life, these heresies passed away without solid results and were forgotten.

Naturalism.—We are apt to take for granted that the men of the middle ages were immersed in meditations on the other world, and that their intellectual exercises were confined to abstractions of the schools, hallucinations of the fancy, allegories, visions. This assumption applies indeed in a broad sense to that period which was dominated by intolerant theology, and deprived of positive knowledge. Yet there are abundant signs that the native human instincts, the natural human appetities, remained unaltered and alive beneath the crust of orthodoxy. In the person of a pope like Boniface VIII. those ineradicable forces of the natural man assumed, if we may trust the depositions of ecclesiastics, well acquainted with his life, a form of brutal atheistic cynicism. In the person of an emperor, Frederick II., they emerged under the more agreeable garb of liberal culture and Epicurean scepticism. Frederick dreamed of remodelling society upon a mundane type, which anticipated the large toleration and cosmopolitan enlightenment of the actual Renaissance. But his efforts were defeated by the unrelenting hostility of the Church, and by the incapacity of his contemporaries to understand his aims. After being forced in his lifetime to submit to authority, he was consigned by Dante to hell. Frederick's ideal of civilization was derived in a large measure from Provence, where a beautiful culture had prematurely bloomed, filling southern Europe with the perfume of poetry and gentle living. Here, if anywhere, it seemed as though the ecclesiastical and feudal fetters of the middle ages might be broken, and humanity might enter on a new stage of joyous and unimpeded evolution. This was, however, not to be. The Church preached Simon de Montfort's crusade, and organized Dominic's Inquisition; what Quinet calls the "Renaissance sociale par l'Amour" was extirpated by sword, fire, famine and pestilence. Meanwhile the Provençal poets had developed their modern language with incomparable richness and dexterity, creating forms of verse and modes of emotional expression which determined the latest mediaeval phase of literature in Europe. The naturalism of which we have been speaking found free utterance now in the fabliaux of jongleurs, lyrics of minnesingers, tales of trouvères, romances of Arthur and his knights—compositions varied in type and tone, but in all of which sincere passion and real enjoyment of life pierce through the thin veil of chivalrous mysticism or of allegory with which they were sometimes conventionally draped. The tales of Lancelot and Tristram, the lives of the troubadours and the Wachtlieder of the minnesingers, sufficiently prove with what sensual freedom a knight loved the lady whom custom and art made him profess to worship as a saint. We do not need to be reminded that Beatrice's adorer had a wife and children, or that Laura's poet owned a son and daughter by a concubine, in order to perceive that the mystic passion of chivalry was compatible in the middle ages with commonplace matrimony or vulgar illegitimate connections. But perhaps the most convincing testimony to the presence of this ineradicable naturalism is afforded by the Latin songs of wandering students, known as Carmina Burama, written by the self-styled Goliardi. In these compositions, remarkable for their facile handling of mediaeval Latin rhymes and rhythms, the allegorizing mysticism which envelops chivalrous poetry is discarded. Love is treated from a frankly carnal point of view. Bacchus and Venus go hand in hand, as in the ancient ante-Christian age. The open-air enjoyments of the wood, the field, the dance upon the village green are sung with juvenile light-heartedness. No grave note, warning us that the pleasures of this earth are fleeting, that the visible world is but a symbol of the invisible, that human life is a probation for the life beyond, interrupts the tinkling music as of castanets and tripping feet which gives a novel charm to these unique relics of the 13th century. Goliardic poetry is further curious as showing how the classics even at that early period were a fountain-head of pagan inspiration. In the taverns and low places of amusement haunted by those lettered songsters, on the open road and in the forests trodden by their vagrant feet, the deities of Greece and Rome were not in exile, but at home within the hearts of living men. Thus, while Christendom was still preoccupied with the Crusades, two main forces of the Renaissance, naturalism and enthusiasm for antique modes of feeling, already brought their latent potency to light, prematurely indeed and precociously, yet with a promise that was destined to be kept.

The Mediaeval Attitude.—When due regard is paid to these miscellaneous evidences of intellectual and sensual freedom during the middle ages, it will be seen that there were by no means lacking elements of native vigour ready to burst forth. What was wanting was not vitality and licence, not audacity of speculation, not lawless instinct or rebellious impulse. It was rather the right touch on life, the right feeling for human independence, the right way of approaching the materials of philosophy, religion, scholarship and literature that failed. The courage that is born of knowledge, the calm strength begotten by a positive attitude of mind, face to face with the dominant over-shadowing sphinx of theology, were lacking. We may fairly say that natural and untaught people had more of the just intuition that was needed than learned folk trained in the schools. But these people were rendered licentious in revolt or impotent for salutary action by ignorance, by terror, by uneasy dread of the doom declared for heretics and rebels.

The massive vengeance of the Church hung over them, like a heavy sword suspended in the cloudy air. Superstition and stupidity hedged them in on every side, so that sorcery and magic seemed the only means of winning power over nature or insight into mysteries surrounding human life. The path from darkness to light was lost; thought was involved in allegory; the study of nature had been perverted into an inept system of grotesque and pious parable-mongering; the pursuit of truth had become a game of wordy dialectics. The other world, with its imagined heaven and hell, haunted the conscience like a nightmare. However sweet this world seemed, however fair the flesh, both world and flesh were theoretically given over to the devil. It was not worth while to master and economize the resources of this earth, to utilize the good and ameliorate the evils of this life, while every one agreed, in theory at any rate, that the present was but a bad prelude to an infinitely worse or infinitely better future. To escape from these preoccupations and prejudices except upon the path of conscious and deliberate sin was impossible for all but minds of rarest quality and courage; and these were too often reduced to the recantation of their supposed errors no less than by some secret clinging sense of guilt than by the Church's iron hand. Man and the actual universe kept on reasserting their rights and claims, announcing their goodliness and delightfulness, in one way or another; but they were always being thrust back again into Cimmerian regions of abstractions, fictions, visions, spectral hopes and fears, in the midst of which the intellect somnambulistically moved upon an unknown way.

THE REVIVAL OF LEARNING IN ITALY

At this point the Revival of Learning intervened to determine the course of the Renaissance. Mediaeval students possessed a considerable portion of the Latin classics, though Greek had become in the fullest sense of the phrase a dead language. But what they retained of ancient literature they could not comprehend in the right spirit. Between them and the text of poet or historian hung a veil of mysticism, a vapour of misapprehension. The odour of unsanctity clung around those relics of the pagan past. Men bred in the cloister and the lecture-room of the logicians, trained in scholastic disputations, versed in allegorical interpretations of the plainest words and most apparent facts, could not find the key which might unlock those stores of wisdom and of beauty. Petrarch first opened a new method in scholarship, and revealed what we denote as humanism. In his teaching lay the twofold discovery of man and of the world. For humanism, which was the vital element in the Revival of Learning, consists mainly of a just perception of the dignity of man as a rational, volitional and sentient being, born upon this earth with a right to use it and enjoy it. Humanism implied the rejection of those visions of a future and imagined state of souls as the only absolute reality, which had fascinated the imagination of the middle ages. It involved a vivid recognition of the goodliness of man and nature, displayed in the great monuments of human power recovered from the past. It stimulated the curiosity of latent sensibilities, provoked fresh inquisition into the groundwork of existence and strengthened man's self-esteem by knowledge of what men had thought and felt and done in ages when Christianity was not. It roused a desire to reappropriate the whole abandoned provinces of mundane energy, and a hope to emulate antiquity in works of living loveliness and vigour. The Italians of the 14th century, more precocious than the other European races, were ripe for this emancipation of enslaved intelligence. In the classics they found the food which was required to nourish the new spirit; and a variety of circumstances among which must be reckoned the pride of a nation boasting of its descent from the Populus Romanus, rendered them apt to fling aside the obstacles that had impeded the free action of the mind through many centuries. Petrarch not only set his countrymen upon the right method of studying the Latin classics, but he also divined the importance of recovering a knowledge of Greek literature. To this task Boccaccio addressed himself; and he was followed by numerous Italian enthusiasts, who visited Byzantium before its fall as the sacred city of a new revelation. The next step was to collect mss., to hunt out, copy and preserve the precious relics of the past. In this work of accumulation Guarino and Filelfo, Aurispa and Poggio, took the chief part, aided by the wealth of Italian patricians, merchant-princes and despots, who were inspired by the sacred thirst for learning. Learning was then no mere pursuit of a special and recluse class. It was fashionable and it was passionate, pervading all society with the fervour of romance. For a generation nursed in decadent scholasticism and stereotyped theological formulae it was the fountain of renascent youth, beauty and freedom, the shape in which the Helen of art and poetry appeared to the ravished eyes of mediaeval Faustus. It was the resurrection of the mightiest spirits of the past. "I go," said Cyriac of Ancona, the indefatigable though uncritical explorer of antiquities, "I go to awake the dead!" This was the enthusiasm, this the vitalizing faith, which made the work of scholarship in the 15th century so highly strung and ardent. The men who followed it knew that they were restoring humanity to its birthright after the expatriation of ten centuries. They were instinctively aware that the effort was for liberty of action, thought and conscience in the future. This conviction made young men leave their loves and pleasures, grave men quit their counting-houses, churchmen desert their missals, to crowd the lecture-rooms of philologers and rhetoricians. When Greek had been acquired, mss. accumulated, libraries and museums formed, came the age of printers and expositors. Aldus Manutius in Italy, Froben in Basel, the Étiennes in Paris, committed to the press what the investigators had recovered. Nor were there wanting men who dedicated their powers to Hebrew and Oriental erudition, laying, together with the Grecians, a basis for those Biblical studies which advanced the Reformation. Meanwhile the languages of Greece and Rome had been so thoroughly appropriated that a final race of scholars, headed by Politian, Pontano, Valla, handled once again in verse and prose both antique dialects, and thrilled the ears of Europe with new-made pagan melodies. The Church itself at this epoch lent its influence to the prevalent enthusiasm. Nicholas V. and Leo X., not to mention intervening popes who showed themselves tolerant of humanistic culture, were heroes of the classical revival. Scholarship became the surest path of advancement to ecclesiastical and political honours. Italy was one great school of the new learning at the moment when the German, French and Spanish nations were invited to her feast.

It will be well to describe briefly, but in detail, what this meeting of the modern with the ancient mind effected over the whole field of intellectual interests. In doing so, we must be careful to remember that the study of the classics did but give a special impulse to pent-up energies which were bound in one way or another to assert their independence. Without the Revival of Learning the direction of those forces would have been different; but that novel intuition into the nature of the world and man which constitutes what we describe as Renaissance must have emerged. As the facts, however, stand before us, it is impossible to dissociate the rejection of the other world as the sole reality, the joyous acceptance of this world as a place to live in and act in, the conviction that "the proper study of mankind is man," from humanism. Humanism as it actually appeared in Italy was positive in its conception of the problems to be solved, pagan in its contempt for mediaeval mysticism, invigorated for sensuous enjoyment by contact with antiquity, yet holding in itself the germ of new religious aspirations, profounder science and sterner probings of the mysteries of life than had been attempted even by the ancients. The operation of this humanistic spirit has now to be traced.

Dante, Petrarch, Boccaccio, and Villani.—It is obvious that Italian literature owed little at the outset to the Revival of Learning. The *Divine Comedy*, the *Canzoniere* and the *Decameron* were works of monumental art, deriving neither form nor inspiration immediately from the classics but applying the originality of Italian genius to matter drawn from previous mediaeval sources. Dante showed both in his epic poem and in his lyrics that he had not abandoned the sphere of contemporary thought. Allegory and theology, the vision and the symbol, still determine the form of masterpieces which for perfection of workmanship and for emancipated force of intellect rank among the highest products of the

human mind. Yet they are not mediaeval in the same sense as the song of Roland or the Arthurian cycle. They proved that, though Italy came late into the realm of literature, her action was destined to be decisive and alterative by the introduction of a new spirit, a firmer and more positive grasp on life and art. These qualities she owed to her material prosperity, to her freedom from feudalism, to her secularized church, her commercial nobility, her political independence in a federation of small states. Petrarch and Boccaccio, though they both held the mediaeval doctrine that literature should teach some abstruse truth beneath a veil of fiction, differed from Dante in this, that their poetry and prose in the vernacular abandoned both allegory and symbol. In their practice they ignored their theory; Petrarch's lyrics continue the Provençal tradition as it had been reformed in Tuscany, with a subtler and more modern analysis of emotion, a purer and more chastened style than his masters could boast; Boccaccio's tales, in like manner, continue the tradition of the fabliaux, raising that literary species to the rank of finished art, enriching it with humour and strengthening its substance by keen insight into all varieties of character. The *Canzoniere* and the *Decamcron* distinguish themselves from mediaeval literature, not by any return to classical precedents, but by free self-conscious handling of human nature. So much had to be premised in order to make it clear in what relation humanism stood to the Renaissance since the Italian work of Dante, Petrarch and Boccaccio is sufficient to indicate the re-birth of the spirit after ages of apparent deadness. Had the Revival of Learning not intervened, it is probable that the vigorous efforts of these writers alone would have inaugurated a new age of European culture. Yet, while noting this reservation of judgment it must also be remarked that all three felt themselves under some peculiar obligation to the classics. Dante, mediaeval as his temper seems to us, chose Virgil for his guide, and ascribed his mastery of style to the study of Virgilian poetry. Petrarch and Boccaccio were, as we have seen, the pioneers of the new learning. They held their writings in the vernacular cheap, and initiated that contempt for the mother tongue which was a note of the earlier Renaissance. Giovanni Villani, the first chronicler who used Italian for the compilation of a methodical history, tells us how he was impelled to write by musing on the ruins of Rome, and thinking of the vanished greatness of the Latin race. We have, therefore, to recognize that the four greatest writers of the 14th century, while the Revival of Learning was yet in its cradle, each after his own fashion acknowledged the vivifying touch upon his spirit of the antique genius. They seem to have been conscious that they could not give the desired impulse to modern literature and art without contact with the classics; and, in spite of the splendour of their achievements in Italian, they found no immediate followers upon that path.

Scholarship and Literature.—The fascination of pure study was so powerful, the Italians at that epoch were so eager to recover the past, that during the 15th century we have before our eyes the spectacle of this great nation deviating from the course of development begun in poetry by Dante and Petrarch, in prose by Boccaccio and Villani, into the channels of scholarship and antiquarian research. The language of the *Canzoniere* and *Decameron* was abandoned for revived Latin and discovered Greek. Acquisition supplanted invention; imitation of classical authors suppressed originality of style. The energies of the Italian people were devoted to transcribing the codices, settling texts, translating Greek books into Latin, compiling grammars, commentaries, encyclopaedias, dictionaries, epitomes and ephemerides. During this century the best histories—Bruni's and Poggio's annals of Florence, for example—were composed in Latin after the manner of Livy. The best dissertations, Landino's *Camaldunenses*, Valla's *De Voluptate*, were laboured imitations of Cicero's *Tusculans*. The best verse, Pontano's elegies, Politian's hexameters, were, in like manner Latin; public orations upon ceremonial occasions were delivered in the Latin tongue; correspondence, official and familiar, was carried on in the same language; even the fabliaux received, in Poggio's *Facetiae*, a dress of elegant Latinity. The noticeable barrenness of Italian literature at this period is referable to the fact that men of genius and talent devoted themselves to erudition and struggled to express their thoughts and feelings in a speech which was not natural. Yet they were engaged in a work of incalculable importance. At the close of the century the knowledge of Greece and Rome had been reappropriated and placed beyond the possibility of destruction; the chasm between the old and new world had been bridged; mediaeval modes of thinking and discussing had been superseded; the staple of education, the common culture which has brought all Europe into intellectual agreement, was already in existence. Humanism was now an actuality. Owing to the uncritical veneration for antiquity which then prevailed, it had received a strong tincture of pedantry. Its professors, in their revolt against the middle ages, made light of Christianity and paraded paganism. What was even worse from an artistic point of view, they had contracted puerilities of style vanities of rhetoric, stupidities of wearisome citation. Still, at the opening of the 16th century, it became manifest what fruits of noble quality the Revival of Letters was about to bring forth for modern literature. Two great scholars, Lorenzo de'Medici and Politian, had already returned to the practice of Italian poetry Their work is the first absolutely modern work—modern in the sense of having absorbed the stores of classic learning and reproduced those treasures in forms of simple, natural, native beauty Boiardo occupies a similar position by the fusion of classic mythology with chivalrous romance in his *Orlando Innamorato*. But the victor's laurels were reserved for Ariosto whose *Orlando Furioso* is the purest and most perfect extant example of Renaissance poetry. It was not merely in what they had acquired and assimilated from the classics that these poets showed the transformation effected in the fields of literature by humanism. The whole method and spirit of the mediaeval art had been abandoned. That of the *cinque cento* is positive, defined, mundane The deity, if deity there be, that rules in it, is beauty. Interest is confined to the actions, passions, sufferings and joys of human life, to its pathetic, tragic, humorous and sentimental incidents Of the state of souls beyond the grave we hear and are supposed to care nothing. In the drama the pedantry of the Revival which had not injured romantic literature made itself perniciously felt Rules were collected from Horace and Aristotle. Seneca was chosen as the model of tragedy; Plautus and Terence supplied the groundwork of comedy. Thus in the plays of Rucellai, Trissino Sperone and other tragic poets, the nobler elements of humanism considered as a revelation of the world and man, obtained no free development. Even the comedies of the best authors are too observant of Latin precedents, although some pieces of Machiavelli Ariosto, Aretino, Cecchi and Gelli are admirable for vivid delineation of contemporary manners.

Fine Arts.—The relation of the plastic arts to the Revival of Learning is similar to that which has been sketched in the case of poetry. Cimabue started with work which owed nothing directly to antiquity. At about the same time Niccola Pisano (d. 1278) studied the style of sculpture in fragments of Graeco-Roman marbles. His manner influenced Giotto, who set painting on a forward path. Fortunately for the unimpeded expansion of Italian art, little was brought to light of antique workmanship during the 14th and 15th centuries. The classical stimulus came to painters, sculptors and architects chiefly through literature. Therefore there was narrow scope for imitation; and the right spirit of humanism displayed itself in a passionate study of perspective, nature and the nude. Yet we find in the writings of Ghiberti and Alberti, we notice in the masterpieces of these men and their compeers Brunelleschi and Donatello, how even in the 15th century the minds of artists were fascinated by what survived of classic grace and science. Gradually, as the race became penetrated by antique thought, the earlier Christian motives of the arts yielded to pagan subjects. Gothic architecture, which had always flourished feebly on Italian soil, was supplanted by a hybrid Roman style. The study of Vitruvius gave strong support to that pseudo-classic manner which, when it had reached its final point in Palladio's work, overspread the whole of Europe and dominated taste during two centuries. But the perfect plastic art of Italy the pure art of the *cinque cento*, the painting of Raphael, Da Vinci, Titian and Correggio, the sculpture of Donatello, Michel-

angelo and Sansovino, the architecture of Bramante, Omodeo, and the Venetian Lombardi, however much imbued with the spirit of the classical revival, take rank beside the poetry of Ariosto as a free intelligent product of the Renaissance. That is to say, it is not so much an outcome of studies in antiquity as an exhibition of emancipated modern genius fired and illuminated by the masterpieces of the past. It indicates a separation from the middle ages, inasmuch as it is permanently natural. Its religion is joyous, sensuous, dramatic, terrible, but in each and all of its many-sided manifestations strictly human. Its touch on classical mythology is original, rarely imitative or pedantic. The art of the Renaissance was an apocalypse of the beauty of the world and man in unaffected spontaneity, without side thoughts for piety or erudition, inspired by pure delight in loveliness and harmony for their own sakes.

Science and Philosophy.—In the fields of science and philosophy humanism wrought similar important changes. Petrarch began by waging relentless war against the logicians and materialists of his own day. With the advance made in Greek studies scholastic methods of thinking fell into contemptuous oblivion. The newly aroused curiosity for nature encouraged men like Alberti, Da Vinci, Toscanelli and Da Porta to make practical experiments, penetrate the working of physical forces, and invent scientific instruments. Anatomy began to be studied, and the time was not far distant when Titian should lend his pencil to the epoch-making treatise of Vesalius. The middle ages had been satisfied with absurd and visionary notions about the world around them, while the body of man was regarded with too much suspicion to be studied. Now the right method of interrogating nature with patience and loving admiration was instituted. At the same time the texts of ancient authors supplied hints which led to discoveries so far-reaching in their results as those of Copernicus, Columbus and Galileo. In philosophy, properly so called, the humanistic scorn for mediaeval dullness and obscurity swept away theological metaphysics as valueless. But at first little beyond empty rhetoric and clumsy compilation was substituted. The ethical treatises of the scholars are deficient in substance, while Ficino's attempt to revive Platonism betrays an uncritical conception of his master's drift. It was something, however, to have shaken off the shackles of ecclesiastical authority; and, even if a new authority, that of the ancients, was accepted in its stead, still progress was being made toward sounder methods of analysis. This is noticeable in Pomponazzo's system of materialism, based on the interpretation of Aristotle, but revealing a virile spirit of disinterested and unprejudiced research. The thinkers of southern Italy, Telesio, Bruno and Campanella, at last opened the two chief lines on which modern speculation has since moved. Telesio and Campanella may be termed the predecessors of Bacon. Bruno was the precursor of the idealistic schools. All three alike strove to disengage their minds from classical as well as ecclesiastical authority, proving that the emancipation of the will had been accomplished. It must be added that their writings, like every other product of the Renaissance, except its purest poetry and art, exhibit a hybrid between mediaeval and modern tendencies. Childish ineptitudes are mingled with intuitions of maturest wisdom and seeds of future thought germinate in the decaying refuse of past systems.

Criticism.—Humanism in its earliest stages was uncritical. It absorbed the relics of antiquity with omnivorous appetite and with very imperfect sense of the distinction between worse and better work. Yet it led in process of time to criticism. The critique of literature began in the lecture-room of Politian, in the printing house of Aldus, and in the school of Vittorino. The critique of Roman law started under Politian's auspices, upon a more liberal course than that which had been followed by the powerful but narrow-sighted glossators of Bologna. Finally, in the court of Naples arose that most formidable of all critical engines, the critique of established ecclesiastical traditions and spurious historical documents. Valla by one vigorous effort destroyed the False Decretals and exposed the Donation of Constantine to ridicule, paving the way for the polemic carried on against the dubious pretensions of the papal throne by scholars of the Reformation. A similar criticism, conducted less on lines of erudition than of persiflage and irony, ransacked the moral abuses of the Church and played around the very foundations of Christianity. This was tolerated with approval by men who repeated Leo X.'s witty epigram, "What profit has not that fable of Christ brought us!" The same critical and philosophic spirit working on the materials of history produced a new science, the honours of which belong to Machiavelli. He showed, on the one side, how the history of a people can be written with a recognition of fixed principles, and at the same time with an artistic feeling for personal and dramatic episodes. On the other side, he addressed himself to the analysis of man considered as a political being, to the anatomy of constitutions and the classification of governments, to the study of motives underlying public action, the secrets of success and the causes of failure in the conduct of affairs. The unscrupulous rigour with which he applied his scientific method, and the sinister deductions he thought himself justified in drawing from the results it yielded, excited terror and repulsion. Nevertheless a department had been added to the intellectual empire of mankind, in which fellow-workers, like Guicciardini at Florence, and subsequently Sarpi at Venice, were not slow to follow the path traced by Machiavelli.

Education.—The object of the foregoing paragraphs has been to show in what way the positive, inquisitive, secular, exploratory spirit of the Renaissance, when toned and controlled by humanism penetrated the regions of literature, art, philosophy and science. It becomes at this point of much moment to consider how social manners in Italy were modified by the same causes, since the type developed there was in large measure communicated together with the new culture to the rest of Europe. The first subject to be noticed under this heading is education. What has come to be called a classical education was the immediate product of the Italian Renaissance. The Universities of Bologna, Padua, and Salerno had been famous through the later middle ages for the study of law, physics and medicine; and during the 15th and 16th centuries the first two still enjoyed celebrity in these faculties. But at this period no lecture-rooms were so crowded as those in which professors of antique literature and language read passages from the poets and orators, taught Greek, and commented upon the systems of philosophers. The mediaeval curriculum offered no defined place for the new learning of the Revival, which had indeed no recognized name. Chairs had therefore to be founded under the title of rhetoric, from which men like Chrysoloras and Guarino, Filelfo and Politian expounded orally to hundreds of eager students from every town of Italy and every nation of Europe their accumulated knowledge of antiquity. One mass of Greek and Roman erudition, including history and metaphysics, law and science, civic institutions and the art of war, mythology and magistracies, metrical systems and oratory, agriculture and astronomy, domestic manners and religious rites, grammar and philology, biology and numismatics, formed the miscellaneous subject-matter of this so-styled rhetoric. Notes taken at these lectures supplied young scholars with hints for further exploration; and a certain tradition of treating antique authors for the display of general learning, as well as for the elucidation of their texts, came into vogue, which has determined the method of scholarship for the last three centuries in Europe. The lack of printed books in the first period of the Revival, and the comparative rarity of Greek erudition among students, combined with the intense enthusiasm aroused for the new gospel of the classics, gave special value to the personal teaching of these professors. They journeyed from city to city, attracted by promises of higher pay, and allured by ever-growing laurels of popular fame. Each large town established its public study, academy or university—similar institutions under varying designations—for the exposition of the *literae humaniores*. The humanists, or professors of that branch of knowledge, became a class of the highest dignity. They were found in the chanceries of the republics, in the papal curia, in the council chambers of princes, at the headquarters of condottieri, wherever business had to be transacted, speeches to be made and the work of secretaries to be performed. Furthermore, they undertook the charge of private education, opening schools

which displaced the mediaeval system of instruction and taking engagements as tutors in the families of despots, noblemen and wealthy merchants. The academy established by Vittorino da Feltre at Mantua under the protection of Gian Francesco Gonzaga, for the training of pupils of both sexes, might be chosen as the type of this Italian method. His scholars who were lodged in appropriate buildings met daily to hear the master read and comment on the classics. They learned portions of the best authors by heart, exercised themselves in translating from one language to another and practised composition in prose and verse. It was Vittorino's care to see that while their memories were duly stored with words and facts their judgment should be formed by a critical analysis, attention to style and comparison of the authors of a decadent age with those who were acknowledged classics. During the hours of recreation suitable physical exercises, as fencing, riding, and gymnastics, were conducted under qualified trainers. From this sketch it will be seen how closely the educational system which came into England during the reign of the Tudors, and which has prevailed until the present time, was modelled upon the Italian type. English youths who spend their time at Eton between athletic sports and Latin verse, and who take a first class in *Literae Humaniores* at Oxford are pursuing the same course of physical and mental discipline as the princes of Gonzaga or Montefeltro in the 15th century.

The humanists effected a deeply penetrating change in social manners. Through their influence as tutors, professors, orators and courtiers, society was permeated by a fresh ideal of culture. To be a gentleman in Italy meant at this epoch to be a man acquainted with the rudiments at least of scholarship, refined in diction, capable of corresponding or of speaking in choice phrases, open to the beauty of the arts, intelligently interested in archaeology, taking for his models of conduct the great men of antiquity, rather than the saints of the Church. He was also expected to prove himself an adept in physical exercises and in the courteous observances which survived from chivalry. The type is set before us by Castiglione in that book upon the courtier which went the round of Europe in the 16th century. It is further emphasized in a famous passage of the *Orlando Innamorato* where Boiardo compares the Italian ideal of an accomplished gentleman with the coarser type admired by nations of the north. To this point the awakened intelligence of the Renaissance, instructed by humanism, polished by the fine arts, expanding in genial conditions of diffused wealth, had brought the Italians at a period when the rest of Europe was comparatively barbarous.

Defects of the Renaissance.—This picture has undoubtedly a darker side. Humanism in its revolt against the middle ages was, as we have seen already, mundane, pagan, irreligious, positive[1]. The Renaissance can, after all, be regarded only as a period of transition in which much of the good of the past was sacrificed while some of the evil was retained, and neither the bad nor the good of the future was brought clearly into fact. Beneath the surface of brilliant social culture lurked gross appetites and savage passions, unrestrained by mediaeval piety, untutored by modern experience. Italian society exhibited an almost unexampled spectacle of literary, artistic and courtly refinement crossed by brutalities of lust, treasons, poisonings, assassinations, violence. A succession of worldly pontiffs brought the Church into flagrant discord with the principles of Christianity. Steeped in pagan learning, desirous of imitating the manners of the ancients, thinking and feeling in harmony with Ovid and Theocritus, and at the same time rendered cynical by the corruption of papal Rome, the educated classes lost their grasp upon morality. Political honesty ceased almost to have a name in Italy. The Christian virtues were scorned by the foremost actors and the ablest thinkers of the time, while the antique virtues were themes for rhetoric rather than moving springs of conduct. This is apparent to all students of Machiavelli and Guicciardini, the profoundest analysts of their age, the bitterest satirists of its vices, but themselves infected with its incapacity for moral goodness. The Italians were not only vitiated; they had also become impotent for action and resistance. At the height of the Renaissance the five great Powers in the peninsula formed a confederation of independent but mutually attractive and repellent states. Equilibrium was maintained by diplomacy, in which the humanists played a foremost part, casting a network of intrigue over the nation which helped in no small measure to stimulate intelligence and create a common medium of culture, but which accustomed statesmen to believe that everything could be achieved by wire-pulling. Wars were conducted on a showy system by means of mercenaries, who played a safe game in the field and developed a system of bloodless campaigns. Meanwhile the people grew up unused to arms. When Italy between the years 1494 and 1530 became the battlefield of French, German and Spanish forces, it was seen to what a point of helplessness the political, moral and social conditions of the Renaissance had brought the nation.

[1] But there was also a great school of Christian humanists intent upon reconciling the gospel with the Greek philosophers.

Spread of the New Learning.—It was needful to study at some length the main phenomena of the Renaissance in Italy, because the history of that phase of evolution in the other Western races turns almost entirely upon points in which they either adhered to or diverged from the type established there. Speaking broadly, what France, Germany, Spain and England assimilated from Italy at this epoch was in the first place the new learning as it was then called. This implied the new conception of human life, the new interest in the material universe, the new method of education, and the new manners, which we have seen to be inseparable from Italian humanism. Under these forms of intellectual enlightenment and polite culture the renascence of the human spirit had appeared in Italy, where it was more than elsewhere connected with the study of classical antiquity. But that audacious exploratory energy which formed the motive force of the Renaissance as distinguished from the Revival of Learning took, as we shall see, very different directions in the several nations who now were sending the flower of their youth to study at the feet of Italian rhetoricians.

The Renaissance ran its course in Italy with strange indifference to consequences. The five great Powers, held in equilibrium by Lorenzo de' Medici, dreamed that the peninsula could be maintained *in statu quo* by diplomacy. The Church saw no danger in encouraging a pseudo-pagan ideal of life, violating its own principle of existence by assuming the policy of an aggrandizing secular state, and outraging Christendom openly by its acts and utterances. Society at large was hardly aware that an intellectual force of stupendous magnitude and incalculable explosive power had been created by the new learning. Why should not established institutions proceed upon the customary and convenient methods of routine, while the delights of existence were augmented, manners polished, arts developed and a golden age of epicurean ease made decent by a state religion which no one cared to break with because no one was left to regard it seriously? This was the attitude of the Italians when the Renaissance, which they had initiated as a thing of beauty, began to operate as a thing of power beyond the Alps.

GERMANY

Germany was already provided with universities, seven of which had been founded between 1348 and 1409. In these haunts of learning the new studies took root after the year 1440, chiefly through the influence of travelling professors, Peter Luder and Samuel Karoch. German scholars made their way to Lombard and Tuscan lecture-rooms, bringing back the methods of the humanists. Greek, Latin and Hebrew erudition soon found itself at home on Teutonic soil. Like Italian men of letters, these pioneers of humanism gave a classic turn to their patronymics: unfamiliar names, Crotus Rubeanus and Pierius Graecus, Capnion and Lupambulus Ganymedes, Oecolampadius and Melanchthon, resounded on the Rhine. A few of the German princes, among whom Maximilian, the prince cardinal Albert of Mainz, Frederick the Wise of Saxony, and Eberhard of Württemberg deserve mention, exercised a not insignificant influence on letters by the foundation of new universities and the patronage of learned men. The cities of Strasbourg, Nuremberg, Augsburg, Basle, became centres of learned coteries which gathered round scholars like Wimphel-

ing, Brant, Peutinger, Schedel, and Pirckheimer, artists like Dürer and Holbein, painters of the eminence of Froben. Academies in imitation of Italian institutions came into existence, the two most conspicuous named after the Rhine and the Danube, holding their headquarters respectively at Heidelberg and Vienna. Crowned poets, of whom the most eminent was Conrad Celtes Protucius (Pickel!) emulated the fame of Politian and Pontano. Yet though the Renaissance was thus widely communicated to the centres of German intelligence, it displayed a different character from that which it assumed in Italy. Gothic art, which was indigenous in Germany, yielded but little to southern influences. Such work as that of Dürer, Vischer, Cranach, Schöngauer, Holbein, consummate as it was in technical excellence, did not assume Italian forms of loveliness, did not display the paganism of the Latin races. The modification of Gothic architecture by pseudo-Roman elements of style was incomplete. What Germany afterwards took of the Palladian manner was destined to reach it on a circuitous route from France. In like manner the new learning failed to penetrate all classes of society with the rapidity of its expansion in Italy, nor was the new ideal of life and customs so easily substituted for the mediaeval. The German aristocracy, as Aeneas Sylvius had noticed, remained for the most part barbarous, addicted to gross pleasures, contemptuous of culture. The German dialects were too rough to receive that artistic elaboration under antique influences which had been so facile in Tuscany. The doctors of the universities were too wedded to their antiquated manuals and methods, too satisfied with dullness, too proud of titles and diplomas, too anxious to preserve ecclesiastical discipline and to repress mental activity, for a genial spirit of humanism to spread freely. Not in Cologne or Tübingen but in Padua and Florence did the German pioneers of the Renaissance acquire their sense of liberal studies. And when they returned home they found themselves encumbered with stupidities, jealousies and rancours. Moreover the temper of these more enlightened men was itself opposed to Italian indifference and immorality; it was pugnacious and polemical, eager to beat down the arrogance of monks and theologians rather than to pursue an ideal of aesthetical self-culture. To a student of the origins of German humanism it is clear that something very different from the Renaissance of Lorenzo de' Medici and Leo X. was in preparation from the first upon Teutonic soil. Far less plastic and form-loving than the Italian, the German intelligence was more penetrative, earnest, disputative, occupied with substantial problems. Starting with theological criticism, proceeding to the stage of solid studies in the three learned languages, German humanism occupied the attention of a widely scattered sect of erudite scholars; but it did not arouse the interest of the whole nation until it was forced into a violently militant attitude by Pfefferkorn's attack on Reuchlin. That attempt to extinguish honest thought prepared the Reformation; and humanism after 1518 was absorbed in politico-religious warfare.

Humanism and the German Reformation.—The point of contact between humanism and the Reformation in Germany has to be insisted on; for it is just here that the relation of the Reformation to the Renaissance in general makes itself apparent. As the Renaissance had its precursory movements in the mediaeval period, so the German Reformation was preceded by Wycliffe and Huss, by the discontents of the Great Schism, and by the councils of Constance and Basel. These two main streams of modern progress had been proceeding upon different tracks to diverse issues, but they touched in the studies stimulated by the Revival, and they had a common origin in the struggle of the spirit after self-emancipation. Johann Reuchlin, who entered the lecture-room of Argyropoulos at Rome in 1482, Erasmus of Rotterdam, who once dwelt at Venice as the house guest of the Aldi, applied their critical knowledge of Hebrew and Greek to the elucidation and diffusion of the Bible. To the Germans, as to all nations of that epoch, the Bible came as a new book, because they now read it for the first time with eyes opened by humanism. The touch of the new spirit which had evolved literature, art and culture in Italy sufficed in Germany to recreate Christianity. This new spirit in Italy emancipated human intelligence by the classics; in Germany it emancipated the human conscience by the Bible. The indignation excited by Leo X.'s sale of indulgences, the moral rage stirred in Northern hearts by papal abominations in Rome were external causes which precipitated the schism between Teutonic and Latin Christianity. The Reformation, inspired by the same energy of resuscitated life as the Renaissance, assisted by the same engines of the printing-press and paper, using the same apparatus of scholarship, criticism, literary skill, being in truth another manifestation of the same world-movement under a diverse form, now posed itself as an irreconcilable antagonist to Renaissance Italy. It would be difficult to draw any comparison between German and Italian humanists to the disparagement of the former. Reuchlin was no less learned than Pico; Melanchthon no less humane than Ficino; Erasmus no less witty and far more trenchant than Petrarch; Ulrich von Hutten no less humorous than Folengo; Paracelsus no less fantastically learned than Cardano. But the cause in which German intellect and will were enlisted was so different that it is difficult not to make a formal separation between that movement which evolved culture in Italy and that which restored religion in Germany, establishing the freedom of intelligence in the one sphere and the freedom of conscience in the other. The truth is that the Reformation was the Teutonic Renaissance. It was the emancipation of the reason on a line neglected by the Italians, more important indeed in its political consequences, more weighty in its bearing on rationalistic developments than the Italian Renaissance, but none the less an outcome of the same ground-influences. We have already in this century reached a point at which, in spite of stubborn Protestant dogmatism and bitter Catholic reaction, we can perceive how the ultimate affranchisement of man will be the work of both.

The Counter-Reformation.—The German Reformation was incapable of propagating itself in Italy, chiefly for the reason that the intellectual forces which it represented and employed had already found specific outlet in that country. It was not in the nature of the Italians, sceptical and paganized by the revival, to be keenly interested about questions which seemed to revive the scholastic disputes of the middle ages. It was not in their external conditions, suffering as they were from invasions, enthralled by despots, to use the Reformation as a lever for political revolution. Yet when a tumultuary army of so-called Lutherans sacked Rome in 1527, no sober thinker doubted that a new agent had appeared in Europe which would alter the destinies of the peninsula. The Renaissance was virtually closed so far as it concerned Italy, when Clement VII. and Charles V. struck their compact at Bologna in 1530. This compact proclaimed the principle of monarchial absolutism, supported by papal authority, itself monarchially absolute, which influenced Europe until the outbreak of the Revolution. A reaction immediately set in both against the Renaissance and the Reformation. The Council of Trent, opened in 1545 and closed in 1563, decreed a formal purgation of the Church, affirmed the fundamental doctrines of Catholicism, strengthened the papal supremacy, and inaugurated that movement of resistance which is known as the Counter-Reformation. The complex onward effort of the modern nations, expressing itself in Italy as Renaissance, in Germany as Reformation, had aroused the forces of conservatism. The four main instruments of the reaction were the papacy, which had done so much by its sympathy with the revival to promote the humanistic spirit it now dreaded, the strength of Spain, and two Spanish institutions planted on Roman soil—the Inquisition and the Society of Jesus. The principle contended for and established by this reaction was absolutism as opposed to freedom—monarchial absolutism, papal absolutism, the suppression of energies liberated by the Renaissance and the Reformation. The partial triumph of this principle was secure, in as much as the majority of established powers in Church and State felt threatened by the revolutionary opinions afloat in Europe. Renaissance and Reformation were, moreover, already at strife. Both, too, were spiritual and elastic tendencies toward progress, ideals rather than solid organisms.

SPAIN

The part played by Spain in this period of history was deter-

mined in large measure by external circumstance. The Spaniards became one nation by the conquest of Granada and the union of the crowns of Castile and Aragon. The war of national aggrandizement being in its nature a crusade, inflamed the religious enthusiasm of the people. It was followed by the expulsion of Jews and Moors, and by the establishment of the Inquisition on a solid basis, with powers formidable to the freedom of all Spaniards from the peasant to the throne. These facts explain the decisive action of the Spanish nation on the side of Catholic conservatism, and help us to understand why their brilliant achievements in the field of culture during the 16th century were speedily followed by stagnation. It will be well, in dealing with the Renaissance in Spain, to touch first upon the arts and literature, and then to consider those qualities of character in action whereby the nation most distinguished itself from the rest of Europe. Architecture in Spain, emerging from the Gothic stage, developed an Early Renaissance style of bewildering richness by adopting elements of Arabic and Moorish decoration. Sculpture exhibited realistic vigour of indubitably native stamp; and the minor plastic crafts were cultivated with success on lines of striking originality. Painting grew from a homely stock, until the work of Velasquez showed that Spanish masters in this branch were fully abreast of their Italian compeers and contemporaries. To dwell here upon the Italianizing versifiers, moralists and pastoral romancers who attempted to refine the vernacular of the *Romancero* would be superfluous. They are mainly noticeable as proving that certain coteries in Spain were willing to accept the Italian Renaissance. But the real force of the people was not in this courtly literary style. It expressed itself at last in the monumental work of *Don Quixote,* which places Cervantes beside Rabelais, Ariosto and Shakespeare as one of the four supreme exponents of the Renaissance. The affectations of decadent chivalry disappeared before its humour; the lineaments of a noble nation, animated by the youth of modern Europe emerging from the middle ages, were portrayed in its enduring pictures of human experience. The Spanish drama, meanwhile untrammelled by those false canons of pseudo-classic taste which fettered the theatre in Italy and afterwards in France, rose to an eminence in the hands of Lope de Vega and Calderon which only the English, and the English only in the masterpieces of three or four playwrights, can rival. Camoens in the *Lusiad,* if we may here group Portugal with Spain, was the first modern poet to compose an epic on a purely modern theme, vying with Virgil, but not bending to pedantic rules, and breathing the spirit of the age of heroic adventures and almost fabulous discoveries into his melodious numbers. What has chiefly to be noted regarding the achievements of the Spanish race in arts and letters at this epoch is their potent national originality. The revival of learning produced in Spain no slavish imitation as it did in Italy, no formal humanism, and, it may be added, very little of fruitful scholarship. The Renaissance here, as in England, displayed essential qualities of intellectual freedom, delight in life, exultation over rediscovered earth and man. The note of Renaissance work in Germany was still Gothic. This we feel in the penetrative earnestness of Dürer, in the homeliness of Hans Sachs, in the grotesque humour of *Eulenspiegel,* and the *Narrenschiff,* the sombre pregnancy of the Faust legend, the almost stolid mastery of Holbein. It lay not in the German genius to escape from the preoccupations and the limitations of the middle ages, for this reason mainly that what we call mediaeval was to a very large extent Teutonic. But on the Spanish peninsula, in the masterpieces of Velasquez, Cervantes, Camoens, Calderon, we emerge into an atmosphere of art definitely national, distinctly modern, where solid natural forms stand before us realistically modelled, with light and shadow on their rounded outlines, and where the airiest creatures of the fancy take shape and weave a dance of rhythmic, light, incomparable intricacy. The Spanish Renaissance would in itself suffice, if other witnesses were wanting, to prove how inaccurate is the theory that limits this movement to the revival of learning. Touched by Italian influences, enriched and fortified by the new learning, Spanish genius walked firmly forward on its own path. It was crushed only by forces generated in the nation that produced it, by the Inquisition and by despotic Catholic absolutism.

In the history of the Renaissance, Spain and Portugal represent the exploration of the ocean and the colonization of the other hemisphere. The voyages of Columbus and Vespucci to America, the rounding of the Cape by Diaz and the discovery of the sea road to India by Vasco da Gama, Cortés's conquest of Mexico and Pizarro's conquest of Peru, marked a new era for the human race and inaugurated the modern age more decisively than any other series of events has done. It has recently been maintained that modern European history is chiefly an affair of competition between confederated states for the possession of lands revealed by Columbus and Da Gama. Without challenging or adopting this speculation, it may be safely affirmed that nothing so pregnant of results has happened as this exploration of the globe. To say that it displaced the centre of gravity in politics and commerce, substituting the ocean for the Mediterranean, dethroning Italy from her seat of central importance in traffic, depressing the eastern and elevating the western Powers of Europe, opening a path for Anglo-Saxon expansiveness, forcing philosophers and statesmen to regard the Occidental nations as a single group in counterpoise to other groups of nations, the European community as one unit correlated to other units of humanity upon this planet, is truth enough to vindicate the vast significance of these discoveries. The Renaissance, far from being the re-birth of antiquity with its civilization confined to the Mediterranean and the Hercules' Pillars beyond which lay Cimmerian darkness, was thus effectively the entrance upon a quite incalculably wider stage of life on which mankind at large has since enacted one great drama.

While Spanish navies were exploring the ocean, and Spanish paladins were overturning empires, Charles V. headed the reaction of Catholicism against reform. Stronger as king of Spain than as emperor, for the Empire was little but a name, he lent the weight of his authority to that system of coercion and repression which enslaved Italy, desolated Germany with war, and drowned the Low Countries in blood. Philip II., with full approval of the Spanish nation, pursued the same policy in an even stricter spirit. He was powerfully assisted by two institutions in which the national character of Spain expressed itself, the Inquisition and the Society of Jesus. Of the former it is not needful to speak here. But we have to observe that the last great phenomenon of the Spanish Renaissance was Ignatius Loyola, who organized the militia by means of which the Church worked her Counter-Reformation. His motto, *Perinde ac cadaver,* expressed that recognition of absolutism which papacy and monarchy demanded for their consolidation. (*See* JESUITS and LOYOLA.)

FRANCE

The logical order of an essay which attempts to show how Renaissance was correlated to Reformation and Counter-Reformation has necessitated the treatment of Italy, Germany and Spain in succession; for these three nations were the three main agents in the triple process to be analysed. It was due to their specific qualities, and to the diverse circumstances of their external development that the re-birth of Europe took this form of duplex action on the lines of intellectual and moral progress, followed by reaction against mental freedom. We have now to speak of France, which earliest absorbed the influence of the Italian revival, and of England which received it latest. The Renaissance may be said to have begun in France with Charles VIII.'s expedition to Naples, and to have continued until the extinction of the house of Valois. Louis XII. and Francis I. spent a considerable portion of their reigns in the attempt to secure possession of the Italian provinces they claimed. Henry II.'s queen was Catherine of the Medicean family; and her children, Charles IX. and Henry III., were Italianated Frenchmen. Thus the connection between France and Italy during the period 1494–1589 was continuous. The French passed to and fro across the Alps on military and peaceful expeditions. Italians came to France as courtiers, ambassadors, men of business, captains and artists. French society assumed a strong Italian colouring, nor were the manners of the court very different from those of an Italian city, except that

externally they remained ruder and less polished. The relation between the crown and its great feudatories, the military bias of the aristocracy, and the marked distinction between classes which survived from the middle ages, rendered France in many vital points unlike Italy. Yet the annals of that age, and the anecdotes retailed by Brantôme, prove that the royalty and nobility of France had been largely Italianized.

Architecture.—It is said that Louis XII. brought Fra Giocondo of Verona back with him to France and founded a school of architects. But we need not have recourse to this legend for the explanation of such Italian influences as were already noticeable in the Renaissance buildings on the Loire. Without determining the French style, Italian intercourse helped to stimulate its formation and development. There are students of the 15th century in France who resent this intrusion of the Italian Renaissance. But they forget that France was bound by inexorable laws of human evolution to obey the impulse which communicated itself to every form of art in Europe. In the school of Fontainebleau, under the patronage of Francis I., that Italian influence made itself distinctly felt; yet a true French manner had been already formed, which, when it was subsequently applied at Paris, preserved a marked national quality. The characteristic of the style developed by Bullant, De l'Orme and Lescot, in the royal or princely palaces of Chenonceaux, Chambord, Anet, Écouen, Fontainebleau, the Louvre and elsewhere is a blending of capricious fancy and inventive richness of decoration with purity of outline and a large sense of the beauty of extended masses. Beginning with the older castles of Touraine, and passing onward to the Tuileries, we trace the passage from the mediaeval fortress to the modern pleasure-house, and note how architecture obeyed the special demands of that new phenomenon of Renaissance civilization, the court. In the general distribution of parts these monumental buildings express the peculiar conditions which French society assumed under the influence of Francis I. and Diane de Poitiers. In details of execution and harmonic combinations they illustrate the precision, logic, lucidity and cheerful spirit of the national genius. Here, as in Lombardy, a feeling for serene beauty derived from the study of the antique has not interrupted the evolution of a style indigenous to France and eminently characteristic of the French temperament.

Painting and Sculpture.—During the reign of Francis I. several Italian painters of eminence visited France. Among these Del Rosso, Primaticcio, Del Sarto and Da Vinci are the most famous. But their example was not productive of a really great school of French painting. It was left for the Poussins and Claude Lorraine in the next century, acting under mingled Italian and Flemish influences, to embody the still active spirit of the classical revival. These three masters were the contemporaries of Corneille, and do not belong to the Renaissance period. Sculpture, on the contrary, in which art, as in architecture, the mediaeval French had been surpassed by no other people of Europe, was practised with originality and power in the reigns of Henry II. and Francis I. Ponzio and Cellini, who quitted Italy for France, found themselves outrivalled in their own sphere by Jean Goujon, Cousin and Pilon. The decorative sculpture of this epoch, whether combined with architecture or isolated in monumental statuary, ranks for grace and suavity with the best of Sansovino's. At the same time it is unmistakably inspired by a sense of beauty different from the Italian—more piquant and pointed, less languorous, more mannered perhaps, but with less of empty rhythmical effect. All this while the minor arts of enamelling, miniature, glass-painting, goldsmith's work, jewellery, engraving, tapestry, wood-carving, pottery, etc., were cultivated with a spontaneity and freedom which proved that France, in the middle point between Flanders and Italy, was able to use both influences without a sacrifice of native taste. It may indeed be said in general that what is true of France is likewise true of all countries which felt the artistic impulses of the Renaissance. Whether we regard Spain, the Netherlands, or Germany at this epoch, we find a national impress stamped upon the products of the plastic and the decorative arts, notwithstanding the prevalence of certain forms derived from the antique and Italy. It was only at a later period that the formalism of pseudo-classic pedantry reduced natural and national originality to a dead unanimity.

Literature.—French literature was quick to respond to Renaissance influences. De Comines, the historian of Charles VIII.'s expedition to Naples, differs from the earlier French chroniclers in his way of regarding the world of men and affairs. He has the perspicuity and analytical penetration of a Venetian ambassador. Villon, his contemporary, may rather be ranked, so far as artistic form and use of knowledge are concerned, with poets of the middle ages, and in particular with the Goliardi. But he is essentially modern in the vividness of his self-portraiture, and in what we are wont to call realism. Both De Comines and Villon indicate the entrance of a new quality into literature. The Rhétoriqueurs, while protracting mediaeval traditions by their use of allegory and complicated metrical systems, sought to improve the French language by introducing Latinisms. Thus the Revival of Learning began to affect the vernacular in the last years of the 15th century. Marot and his school reacted against this pedantry. The Renaissance displayed itself in their effort to purify the form and diction of poetry. But the decisive revolution was effected by Ronsard and his comrades of the Pléiade. It was their professed object to raise French to a level with the classics, and to acclimatize Italian species of verse. The humanistic movement led these learned writers to engraft the graces of the antique upon their native literature, and to refine it by emulating the lucidity of Petrarch. The result of their endeavour was immediately apparent in the new force added to French rhythm, the new pomp, richness, colouring and polish conferred upon poetic diction. French style gradually attained to fixity, and the alexandrine came to be recognized as the standard line in poetry. D'Aubigné's invective and Régnier's satire, at the close of the 16th century, are as modern as Voltaire's. Meanwhile the drama was emerging from the mediaeval mysteries; and the classical type, made popular by Garnier's genius, was elaborated, as in Italy, upon the model of Seneca and the canons of the three unities. The tradition thus formed was continued and fortified by the illustrious playwrights of the 17th century. Translation from Greek and Latin into French progressed rapidly at the commencement of this period. It was a marked characteristic of the Renaissance in France to appropriate the spoils of Greece and Rome for the profit of the mother tongue. Amyot's *Plutarch* and his *Daphnis and Chloe* rank amongst the most exquisite examples of beautiful French prose. Prose had now the charm of simplicity combined with grace. To mention Brantôme is to mention the most entertaining of gossips. To speak of Montaigne is to speak of the best as well as the first of essayists. In all the literary work which has been mentioned, the originality and freshness of the French genius are no less conspicuous than its saturation with the new learning and with Italian studies. But the greatest name of the epoch, the name which is synonymous with the Renaissance in France, has yet to be uttered. That, of course, is Rabelais. His incommensurable and indescribable masterpiece of mingled humour, wisdom, satire, erudition, indecency, profundity, levity, imagination, realism, reflects the whole age in its mirror of hyper-Aristophanic farce. What Ariosto is for Italy, Cervantes for Spain, Erasmus for Holland, Luther for Germany, Shakespeare for England, that is Rabelais for France. The Renaissance cannot be comprehended in its true character without familiarity with these six representatives of its manifold and many-sided inspiration.

The Reformation.—The French Renaissance, so rich on the side of arts and letters, was hardly less rich on the side of classical studies. The Revival of Learning has a noble muster-roll of names in France: Turnebus, the patriarch of Hellenistic studies, the Étiennes of Paris, equalling in numbers, industry and learning their Venetian rivals; the two Scaligers; impassioned Dolet; eloquent Muret; learned Cujas; terrible Calvin; Ramus, the intrepid antagonist of Aristotle; De Thou and De Bèze; ponderous Casaubon; brilliant young Saumaise. The distinguishing characteristics of French humanism are vivid intelligence, critical audacity and polemical acumen, perspicuity of exposition, learning directed in its applications by logical sense rather than by artistic ideals of

taste. Some of the names just mentioned remind us that in France, as in Germany and Holland, the Reformation was closely connected with the revival of learning. Humanism has never been in the narrow sense of that term Protestant; still less has it been strictly Catholic. In Italy it fostered a temper of mind decidedly averse to theological speculation and religious earnestness. In Holland and Germany with Erasmus, Reuchlin and Melanchthon it developed types of character, urbane, reflective, pointedly or gently critical, which left to themselves would not have plunged the north of Europe into the whirlpool of belligerent reform. Yet none the less was the new learning, through the open spirit of inquiry it nourished, its vindication of the private reason, its enthusiasm for republican antiquity, and its proud assertion of the rights of human independence, linked by a strong and subtle chain to that turbid revolt of the individual consciousness against spiritual despotism draped in fallacies and throned upon abuses. To this rebellion we give the name of Reformation. But while the necessities of antagonism to papal Rome made it assume at first the form of narrow and sectarian opposition, it marked in fact a vital struggle of the intellect towards truth and freedom, involving future results of scepticism and rationalistic audacity from which its earlier champions would have shrunk. It marked, moreover, in the condition of armed resistance against established authority which was forced upon it by the Counter-Reformation, a firm resolve to assert political liberty, leading in the course of time to a revolution with which the rebellious spirit of the Revival was sympathetic. This being the relation of humanism in general to reform, French learning in particular displayed such innovating boldness as threw many of its most conspicuous professors into the camp at war with Rome. Calvin, a French student of Picard origin, created the type of Protestantism to which the majority of French Huguenots adhered. This too was a moment at which philosophical seclusion was hardly possible. In a nation so tumultuously agitated one side or the other had to be adopted. Those of the French humanists who did not proclaim Huguenot opinions found themselves obliged with Muret to lend their talents to the Counter-Reformation, or to suffer persecution for heterodoxy like Dolet. The Church, terrified and infuriated by the progress of reform, suspected learning on its own account. To be an eminent scholar was to be accused of immorality, heresy and atheism in a single indictment; and the defence of weaker minds lay in joining the Jesuits as Heinsius was fain to do. France had already absorbed the earlier Renaissance in an Italianizing spirit before the Reformation made itself felt as a political actuality. This fact, together with the strong Italian bias of the Valois, serves to explain in some degree the reason why the Counter-Reformation entailed those fierce entangled civil wars, massacres of St. Bartholomew, murders of the Guises, regicides, treasons and empoisonments, that terminated with the compromise of Henry IV. It is no part of the present subject to analyse the political, religious and social interests of that struggle. The upshot was the triumph of the Counter-Reformation, and the establishment of its principle, absolutism, as the basis of French government. It was a French king who, when the nation had been reduced to order, uttered the famous word of absolutism, *"L'État, c'est moi."*

THE NETHERLANDS

The Renaissance in the Low Countries, as elsewhere, had its brilliant age of arts and letters. During the middle ages the wealthy free towns of Flanders flourished under conditions not dissimilar to those of the Italian republics. They raised miracles of architectural beauty, which were modified in the 15th and 16th centuries by characteristic elements of the new style. The Van Eycks, followed by Memling, Metsys, Mabuse, Lucas van Leyden, struck out a new path in the revival of painting and taught Europe the secret of oil-colouring. But it was reserved for the 17th century to witness the flower and fruit time of this powerful art in the work of Porbus, Rubens and Vandyck, in the Dutch schools of landscape and home-life, and in the unique masterpieces of Rembrandt. We have a right to connect this later period with the Renaissance, because the distracted state of the Netherlands during the 16th century suspended, while it could not extinguish, their aesthetic development. The various schools of the 17th century, moreover, are animated with the Renaissance spirit no less surely than the Florentine school of the 15th or the Venetian of the 16th. The animal vigour and carnal enjoyment of Rubens, the refined Italianizing beauty of Vandyck, the mystery of light and gloom on Rembrandt's panels, the love of nature in Ruysdael, Cuyp and Van Hooghe, with their luminously misty skies, silvery daylight and broad expanse of landscape, the interest in common life displayed by Ter Borch, Van Steen, Douw, Ostade and Teniers, the instinct for the beauty of animals in Potter, the vast sea spaces of Vanderveldt, the grasp on reality, the acute intuition into character in portraits, the scientific study of the world and man, the robust sympathy with natural appetites, which distinguish the whole art of the Low Countries, are a direct emanation from the Renaissance.

The vernacular in the Netherlands profited at first but little by the impulse which raised Italian, Spanish, French and English to the rank of classic languages. But humanism, first of all in its protagonist Erasmus, afterwards in the long list of critical scholars and editors, Lipsius, Heinsius and Grotius, in the printers, Elzevir and Plantin, developed itself from the centre of the Leyden university with massive energy, and proved that it was still a motive force of intellectual progress. In the fields of classical learning the students of the Low Countries broke new ground chiefly by methodical collection, classification and comprehensive criticism of previously accumulated stores. Their works were solid and substantial edifices, forming the substratum for future scholarship. In addition to this they brought a philosophy and scientific thoroughness to bear on studies which had been pursued in a more literary spirit. It would, however, be uncritical to pursue this subject further; for the encyclopaedic labours of the Dutch philologers belong to a period when the Renaissance was overpast. For the same reason it is inadmissible to do more than mention the name of Spinoza here.

The Netherlands became the battlefield of Reformation and Counter-Reformation in even a stricter sense than France. Here the antagonistic principles were plainly posed in the course of struggle against foreign despotism. The conflict ended in the assertion of political independence, as opposed to absolute dominion. Europe in large measure owes the modern ideal of political liberty to that spirit of stubborn resistance which broke the power of Spain. Recent history, and, in particular, the history of democracy, claims for its province the several stages whereby this principle was developed in England and America, and its outburst in the frenzy of the French Revolution. It is enough here to have alluded to the part played by the Low Countries in the genesis of a motive force which may be described as the last manifestation of the Renaissance striving after self-emancipation.

ENGLAND

The insular position of England combined with the nature of the English has allowed the country to feel the vibration of European movements later and with less of shock than the continental nations. Before a wave of progress has reached its shores there has been the opportunity of watching it as spectators, and of considering how to receive it. Revolutions have passed from the tumultuous stages of their origin into some settled and recognizable state before we have been called upon to cope with them. It was thus that England took the influences of the Renaissance and Reformation simultaneously, and almost at the same time found herself engaged in that struggle with the Counter-Reformation which, crowned by the defeat of the Spanish Armada, stimulated the sense of nationality and developed the naval forces of the race. Both Renaissance and Reformation had been anticipated by at least a century in England. Chaucer's poetry, which owed so much to Italian examples, gave an early foretaste of the former. Wycliffe's teaching was a vital moment in the latter. But the French wars, the Wars of the Roses and the persecution of the Lollards deferred the coming of the new age; and the year 1536, when Henry VIII. passed the Act of Supremacy through parliament, may be fixed as the date when England entered definitely upon a career of intellectual development abreast

with the foremost nations of the continent. The circumstances just now insisted on explain the specific character of the English Renaissance. The Reformation had been adopted by consent of the king, lords and commons; and this change in the state religion, though it was not confirmed without reaction, agitation and bloodshed, cost the nation comparatively little disturbance. Humanism, before it affected the bulk of the English people, had already permeated Italian and French literature. Classical erudition had been adapted to the needs of modern thought. The hard work of collecting, printing, annotating and translating Greek and Latin authors had been accomplished. The masterpieces of antiquity had been interpreted and made intelligible. Much of the learning popularized by the poets and dramatists was derived at second hand from modern literature. This does not mean that England was deficient in ripe and sound scholars. More, Colet, Ascham, Cheke, Camden were men whose familiarity with the classics was both intimate and easy. Public schools and universities conformed to the modern methods of study; nor were there wanting opportunities for youths of humble origin to obtain an education which placed them on a level with Italian scholars. The single case of Ben Jonson sufficiently proves this. Yet learning did not at this epoch become a marked speciality in England. There was no class corresponding to the humanists. It should also be remembered that the best works of Italian literature were introduced into Great Britain together with the classics. Phaer's *Virgil*, Chapman's *Homer*, Harrington's *Orlando*, Marlowe's *Hero and Leander*, Fairfax's *Jerusalem Delivered*, North's *Plutarch*, Hoby's *Courtier* —to mention only a few examples—placed English readers simultaneously in possession of the most eminent and representative works of Greece, Rome and Italy. At the same time Spanish influences reached them through the imitators of Guevara and the dramatists; French influences in the versions of romances; German influences in popular translations of the Faust legend, *Eulenspiegel*, and similar productions. The authorized versions of the Bible had also been recently given to the people—so that almost at the same period of time England obtained in the vernacular an extensive library of ancient and modern authors. This was a privilege enjoyed in like measure by no other nation. It sufficiently accounts for the richness and variety of Elizabethan literature, and for the enthusiasm with which the English language was cultivated.

Art, Letters, and the Drama.—Speaking strictly, England borrowed little in the region of the arts from other nations, and developed still less that was original. What is called Jacobean architecture marks indeed an interesting stage in the transition from the Gothic style. But, compared with Italian, French, Spanish, German and Flemish work of a like period, it is both timid and dry. Sculpture was represented in London for a brief space by Torrigiani; painting by Holbein and Antonio More; music by Italians and Frenchmen of the Chapel Royal. But no Englishman rose to European eminence in these departments. With literature the case was very different. Wyat and Surrey began by engrafting the forms and graces of Italian poetry upon the native stock. They introduced the sonnet and blank verse. Sidney followed with the sestine and terza rima and with various experiments in classic metres, none of which took root on English soil. The translators handled the octave stanza. Marlowe gave new vigour to the couplet. The first period of the English Renaissance was one of imitation and assimilation. Academies after the Italian type were founded. Tragedies in the style of Seneca, rivalling Italian and French dramas of the epoch, were produced. Attempts to Latinize ancestral rhythms, similar to those which had failed in Italy and France, were made. Tentative essays in criticisms and dissertations on the art of poetry abounded. It seemed as though the Renaissance ran a risk of being throttled in its cradle by superfluity of foreign and pedantic nutriment. But the natural vigour of the English genius resisted influences alien to itself, and showed a robust capacity for digesting the varied diet offered to it. As there was nothing despotic in the temper of the ruling classes, nothing oppressive in English culture, the literature of that age evolved itself freely from the people. It was under these conditions that Spenser gave his romantic epic to the world, a poem which derived its allegory from the middle ages, its decorative richness from the Italian Renaissance, its sweetness, purity, harmony and imaginative splendour from the most poetic nation of the modern world. Under the same conditions, the Elizabethan drama, which in its totality is the real exponent of the English Renaissance, came into existence. This drama very early freed itself from the pseudo-classic mannerism which imposed on taste in Italy and France. Depicting feudalism in the vivid colours of an age at war with feudal institutions, breathing into antique histories the breath of actual life, embracing the romance of Italy and Spain, the mysteries of German legend, the fictions of poetic fancy and the facts of daily life, humours of the moment and abstractions of philosophical speculation, in one homogeneous amalgam instinct with intense vitality, this extraordinary birth of time, with Shakespeare for the master of all ages, left a monument of the Renaissance unrivalled for pure creative power by any other product of that epoch. To complete the sketch, we must set Bacon, the expositor of modern scientific method, beside Spenser and Shakespeare, as the third representative of the Renaissance in England. Nor should Raleigh, Drake, Hawkins, the semi-buccaneer explorers of the ocean, be omitted. They, following the lead of Portuguese and Spaniards, combating the Counter-Reformation on the seas, opened for England her career of colonization and plantation. All this while the political policy of Tudors and Stuarts tended towards monarchial absolutism, while the Reformation in England, modified by contact with the Low Countries during their struggles, was narrowing into strict reactionary intolerance. Puritanism indicated a revolt of the religious conscience of the nation against the arts and manners of the Renaissance, against the encroachments of belligerent Catholicism, against the corrupt and Italianated court of James I., against the absolutist pretensions of his son Charles. In its final manifestation during the Commonwealth, Puritanism won a transient victory over the mundane forces of both Reformation and Renaissance, as these had taken shape in England. It also secured the eventual triumph of constitutional independence. Milton, the greatest humanistic poet of the English race, lent his pen and moral energies during the best years of his life to securing that principle on which modern political systems at present rest. Thus the geographical isolation of England, and the comparatively late adoption by the English of matured Italian and German influences, give peculiar complexity to the phenomena of Reformation and Renaissance simultaneously developed on our island. The period of our history between 1530 and 1642 shows how difficult it is to separate these two factors in the re-birth of Europe, both of which contributed so powerfully to the formation of modern English nationality.

THE NEW EUROPE

It has been impossible to avoid an air of superficiality and the repetition of facts known to every schoolboy in this sketch of so complicated a subject as the Renaissance—embracing many nations, a great variety of topics, and an indefinite period of time. Yet no other treatment was possible upon the lines laid down at the outset, where it was explained why the term Renaissance cannot now be confined to the Revival of Learning and the effect of antique studies upon literary and artistic ideals. The purpose of this article has been to show that, while the Renaissance implied a new way of regarding the material world and human nature, a new conception of man's destiny and duties on this planet, a new culture and new intellectual perceptions penetrating every sphere of thought and energy, it also involved new reciprocal relations between the members of the European group of nations. The Renaissance closed the middle ages and opened the modern era—not merely because the mental and moral ideas which then sprang into activity and owed their force in large measure to the revival of classical learning were opposed to mediaeval modes of thinking and feeling, but also because the political and international relations specific to it as an age were at variance with fundamental theories of the past. Instead of empire and church, the sun and moon of the mediaeval system, a federation of peoples, separate in type, and divergent in interests, yet bound

together by common tendencies, common culture and common efforts came into existence. For obedience to central authority was substituted balance of power. Henceforth the hegemony of Europe attached to no crown, imperial or papal, but to the nation which was capable of winning it, in the spiritual region by mental ascendancy, and in the temporal by force.

That this is the right way of regarding the subject appears from the events of the first two decades of the 16th century, those years in which the humanistic revival attained its highest point in Italy. Luther published his thesis in 1517, 64 years after the fall of Constantinople, 23 years after the expedition of Charles VIII. to Naples, ten years before the sack of Rome, at a moment when France, Spain and England had felt the influences of Italian culture but feebly. From that date forward two parties wrestled for supremacy in Europe, to which may be given the familiar names of Liberalism and Conservatism, the party of progress and the party of established institutions. The triumph of the former was most signal among the Teutonic peoples. The Latin races championed by Spain and supported by the papacy fought the battle of the latter, and succeeded for a time in rolling back the tide of revolutionary conquest. Meanwhile that liberal culture which had been created for Europe by the Italians before the contest of the Reformation began continued to spread, although it was stifled in Italy and Spain, retarded in France and the Low Countries, well-nigh extirpated by wars in Germany and diverted from its course in England by the counter-movement of Puritanism. The *autos da fé* of Seville and Madrid, the flames to which Bruno, Dolet and Paleario were flung, the dungeon of Campanella and the seclusion of Galileo, the massacre of St. Bartholomew and the faggots of Smithfield, the desolated plains of Germany and the cruelties of Alva in the Netherlands, disillusioned Europe of those golden dreams which had arisen in the earlier days of humanism, and which had been so pleasantly indulged by Rabelais. In truth the Renaissance was ruled by no *Astrae redux* but rather by a severe spirit which brought no peace but a sword, reminding men of sternest duties, testing what of moral force and tenacity was in them, compelling them to strike for the old order or the new, suffering no lukewarm halting between two opinions. That, in spite of retardation and retrogression, the old order of ideas should have yielded to the new all over Europe—that science should have won firm standing-ground and political liberty should have struggled through those birth-throes of its origin—was in the nature of things. Had this not been, the Renaissance or re-birth of Europe would be a term without a meaning. (J. A. S.)

While Symonds' article on the Renaissance, originally contributed to the 9th edition of the *Encyclopædia Britannica* remains the classical exposition of a certain view of the subject, more recent research has brought out other aspects of the matter. It is noteworthy, however, that in some important points the very latest investigators have returned to Symonds' conception of the Renaissance, from which historians of the generation immediately following him had departed.

Our continually growing knowledge of the middle ages has thrown the Renaissance into a very different perspective from that in which it was once viewed. Less and less are the centuries preceding the 15th seen as the "Dark Ages" in contrast to the sudden sunrise of modern times. Indeed, many scholars now speak of a Carolingian Renaissance in the 8th century, an Ottonian Renaissance in the 10th, and of the Renaissance of the 12th century, in order to emphasize the constant stream of light and progress throughout the millennium once regarded as a long night of gloom and decadence. On the other hand, many scholars have emphasized even more than did Symonds the extreme gradualness of the efflorescence of the Italian Renaissance and the long persistence in it of mediaeval and Germanic elements. The extreme position is taken by Mr. Henry O. Taylor, who is so impressed by the slowness of the transition from mediaeval to modern times that he would abolish the term "Renaissance" altogether. This proposal, however, has commended itself to few other scholars; there *was* a re-birth of the human mind in the 15th century, though it was not so sudden and decisive as once thought.

In another way our view of the Renaissance has been greatly modified by the economic historians who have stressed the material antecedents of the great political and intellectual movements of the 14th, 15th and 16th centuries. Symonds, like nearly all his contemporaries, wrote almost as if the change in the mental habit of the race were a first cause, unexplained by any alteration in social conditions. But it is now generally accepted that the intellectual change was but the natural result of material conditions altered by the growth of wealth, of commerce, and of city communities. The humanists and artists were dwellers in the cities and in the marts of trade; their patrons were largely found in the newly powerful bourgeoisie of the Italian and German cities. Of course the Renaissance had its intellectual as well as its material antecedents; it was produced by the happy creation in the commercial revolution of a wealthy and leisured class just at a time when discoveries and inventions were thrilling the mind of Western Europe with interest and curiosity. It was no accident that individualism, humanism, and Italian painting attained their majority in the age which saw the invention of printing and the great geographical discoveries of Diaz, of Vasco da Gama, and of Columbus.

Of all the positions taken by Symonds that most subject to attack has been his assertion of the close connection and similar purpose of the Renaissance and Reformation. Like most historians of the 19th century, Symonds regarded them both as liberal movements, emancipations of reason so nearly alike that the Reformation might be called "the Teutonic Renaissance." Just as he was writing, however, Friedrich Nietzsche, basing his opinion on Janssen's *Geschichte des deutschen Volkes seit dem Ausgang des Mittelalters*, which represented the Reformation as a blight on German Catholic civilization, proclaimed that "the Reformation was a reaction of backward minds against the Italian Renaissance": and this view gained ground until it was adopted by Catholic historians like Lord Acton, Protestant historians like Ernst Troeltsch, and generally by the majority of scholars. They have pointed out that the humanists and Reformers came to blows, that the spirit of the Renaissance was largely secular and that of the Reformation intensely religious, that the former was tolerant and often indifferent and sceptical and that the latter was usually intolerant, devout, and sometimes superstitious, that the humanists were aristocratic and the Reformers democratic in method, and that Puritanism proved hostile to and often destructive of the artistic and pleasure-seeking interests of the Renaissance. In criticism of this view, however, it has been contended that the Renaissance was not, any more than the Reformation, consciously progressive; rather did both movements find their ideal in the past, the one in the golden age of Rome and the other in the primitive age of Christianity. It has been further shown that the humanists did little in principle to emancipate the reason from authority; they were closely bound by their own authorities in the classical poets and orators, and could only attack the schoolmen on the basis of the ancient pagans as the Reformers attacked them from the standpoint of the ancient Fathers. In conclusion one may say that neither movement was a conscious appeal to reason or an intentional step forward and away from the past, but that each accomplished, undesignedly, a great work of emancipation and that each created new cultural values.

BIBLIOGRAPHY.—The special articles on the several arts and literatures of modern Europe, and on the biographies of the great men mentioned in this essay, will give the details of necessity here omitted. Of general works, with bibliographies, may be mentioned Jakob Burckhardt, *Die Cultur der Renaissance in Italien*, called by Lord Acton, "the most penetrating and subtle treatise on the history of civilization that exists in literature" (Leipzig, 1st ed. 1860; 20th ed., revised by L. Geiger, 1919; Eng. trans. by S. G. C. Middlemore, 1875); W. H. Pater, *Studies in the History of the Renaissance* (1873); J. A. Troeltsch, "Renaissance und Reformation" in *Historische Zeitschrift* (Munich, vol. cx. pp. 519 ff). (P. S.)

RENAISSANCE ARCHITECTURE. During the 15th, 16th and 17th centuries the structural and decorative elements of Roman architecture (*q.v.*), revived after long disuse, were adapted to the requirements of contemporary buildings throughout Europe. The column and the arch, the dome and groin vault, the arabesque and the rinceau, were conventions from which, in infinite combinations, architects developed their designs. The unity of centralized space and mass, the power of great scale and weight, the repose and completeness of definite and simple development of planes, passages and profiles, and the splendour of richly modelled and coloured surfaces, were the effects most often strived for. Yet Renaissance (*q.v.*) architects did not reproduce, even remotely, a single Roman building; the conditions of life had changed too much for Roman buildings to be practicable.

New Forms.—New and magnificent forms in structure, and in decoration applied to it, were developed. The dome raised on a drum, free from its abutments and crowned with a cupola, was one; when such a dome was raised, by means of pendentives, on four great arches, new and noble harmonies in spatial and mass composition resulted. Façades in which a classic ordinance is adapted to the basilican profile; barrel-vaulted or domed naves; campaniles which end in columned belfries; and vertical spires, encrusted with delicately modelled classic forms, are among the striking inventions of the period. The public buildings of the 15th and 16th centuries—the libraries, town halls, theatres and civic monuments—were utterly different from those of Rome. New combinations of the arch and the column, new rhythms in space, new arrangements in mass, new variations in ornament, had continually to be invented in order to fit the discovered architecture of ancient times to these new uses. Country houses—chateaux and villas, with their gardens—offered another field for adaptation and development; the design of public squares and streets and of buildings in ensembles another; and the vast palaces of the monarchs of France and Spain and England, and of the pope and the princes of the Church another. After three centuries of experiment and growth the Renaissance architect, in the façades of palaces, public buildings and houses, still expressed new ideas in the language of the column and the arch.

In the sixteenth century Europe was neither homogeneous nor centralized. Spain, Italy, Holland, England each had a native culture, a peculiar heritage from the mediaeval world, and each followed a course of development that was, at least in part, independent of all others. Spain, which had defended the Catholic faith against the Moors and which was flooded with the gold of Mexico and Peru, placed on her Renaissance forms a stamp very different from that of commercial and insular England. Monarchical France, rich with the heritage of the 13th century cathedrals, gave necessarily a different metamorphosis to the Italian tradition from Protestant and democratic Holland. Climate, building materials, prosperity, intellectual growth and inherited types of architecture such as the patio of Spain and the timber-roofed hall of England, the turreted chateau of the Loire and the balconied palace of Venice—these and many similar differences in civilization gave the Renaissance a distinctive colour, a special character in each locality.

Great Architects.—Finally there was the influence of individual genius. No period is so crowded with great architects and at no time have architects been so free to impress on their designs the imprint of a great personality. The Roman tradition has been called a tradition of formula and of precedent, yet no tradition has proved so flexible in the hands of a master. It lent itself with equal facility to the requirements of Bramante and of Bernini, of Christopher Wren and Juan de Herrera, of Mansart and of Alessi. It embraced within the limits of a single convention the delicate and gracious lyricism of Lescot, the agitated and passionate declamation of Churriguera, the clear and vigorous rhythms of Inigo Jones, and the mighty harmonies conceived in the illimitable imagination of Michelangelo.

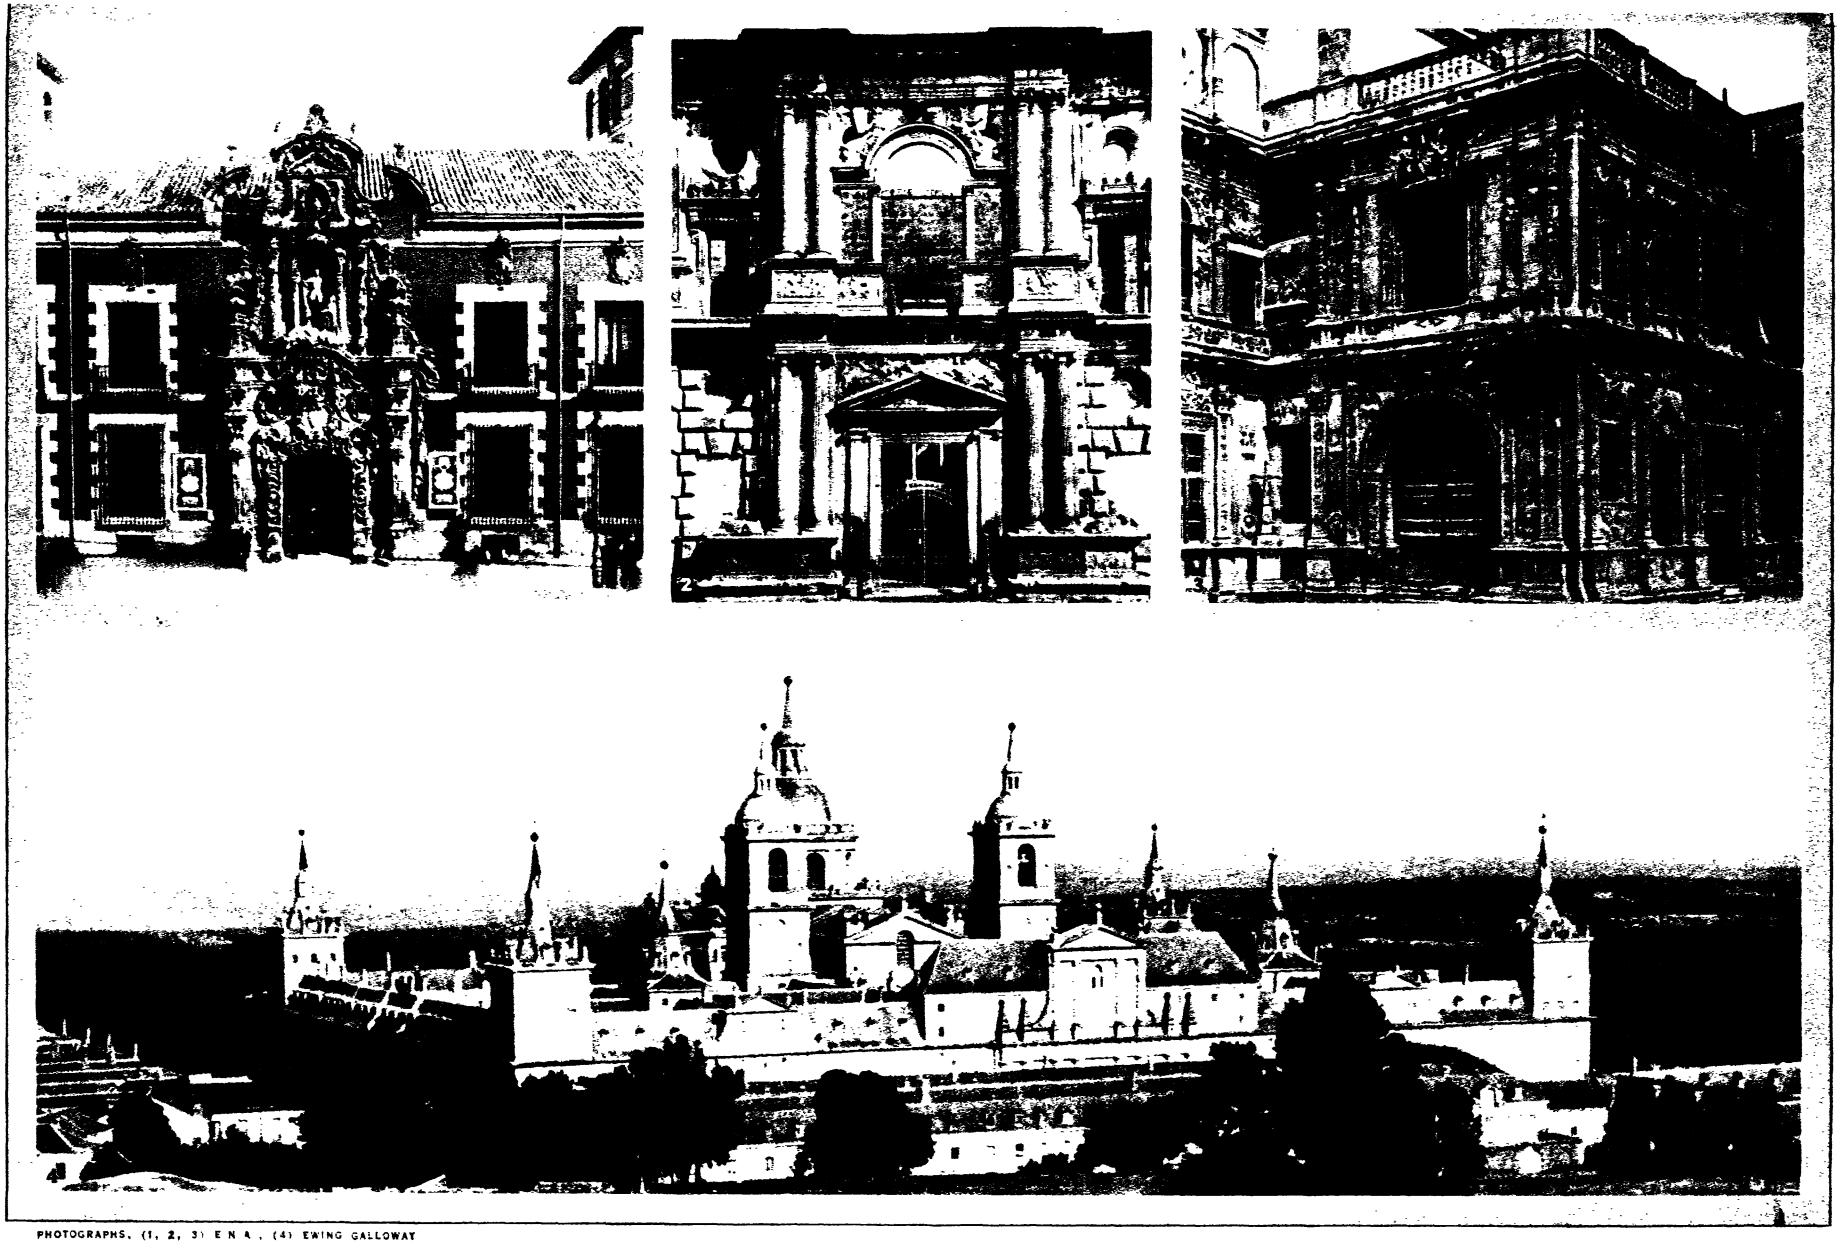
I. RENAISSANCE ARCHITECTURE IN ITALY

Owing to the small hold which the principles of Gothic architecture (*q.v.*) were able to obtain in Italy it is a fair generalization to look upon the architecture of that country from the 3rd century A.D. to the beginning of the 15th as a gradually failing struggle of the builders to retain Roman order and dignity in their undertakings. The early Christian period (*see* BYZANTINE AND ROMANESQUE ARCHITECTURE), no doubt produced, largely through the influence of Byzantine, much brilliant craftsmanship and a great deal of beautiful decoration, but on the whole it is safe to say that all this was applied to buildings in which the structure was decadent Roman. Later on, in what is generally called the Romanesque period the problems of Roman vaulting, now that the art of making concrete was lost, were solved by what to the Romans would have seemed the makeshift arrangement of surface ribs of stone in place of their own buried reinforcements. The clearness of the lines and surfaces of the Roman vaults were thereby interrupted, as were the wall surfaces, by a decoration of pilaster strips and thin arcading. It was the function then of the Renaissance builders—architects we may call them because they did their work with a greater foresight and seriousness of purpose—to bring back the Roman orderliness and precision. In the process they became no mere copiers of the antique. They invented many lovely forms and motives which had, as far as we know, no Roman precedents. As has often been pointed out there is far more difference between a Renaissance church and a Roman temple than between a Roman temple and a Greek one. On the other hand it must be admitted that, even more than in the other arts, there was a strong determination to recover Roman methods both of design and construction. Once the possibility of this was realized the remains of Roman buildings and monuments must have produced a great effect on the imagination. With their far greater scale, if not always greater mass, they must have seemed like the work of a race of giants, no longer to be shunned as something evil but instead, with the striking ambition of a time that produced figures like Galileo and Christopher Columbus, to be equalled and surpassed. The serious study of actual Roman buildings, which was started with Brunelleschi in 1403, gradually gave place, however, after the discovery of the works of Vitruvius, and their dissemination in numberless editions, to an academic interest in his system of proportions for columns, cornices and other details, which stifled real design until the latter was rescued and revivified by Michelangelo and the other giants of the Baroque movement (*see* BAROQUE ARCHITECTURE). The history of the Italian Renaissance, as far as architecture is concerned, is the history of a school of ordered design, which receiving its initial impetus from the antique set out on a new and adventurous career of its own until it was finally bogged by misapplied scholarship.

Brunelleschi.—An appropriate date from which to start is therefore 1403 when Filippo Brunelleschi, a Florentine metal worker by trade and some 26 years of age, having failed in the competition for the bronze doors of the baptistery, left his native town for Rome with the express purpose of studying the Roman remains in that city. The young Donatello, then 16, afterwards to be the famous sculptor, accompanied him "to hold the other end of the tape" as we should say to-day. They stayed away four years and on his return Brunelleschi, with the reputation his knowledge of Roman work gave him, persuaded the council to allow him to

finish the Duomo, which still lacked a covering to the great crossing. For this he designed his famous dome, the first great dome to be raised on a drum. A dome raised on a drum was not a Roman form; neither was Roman construction used; which shows that Brunelleschi's Roman studies had not fettered his imagination. The great raised dome, like that of St. Peter's at Rome, was to become one of the most magnificent and distinctive products of the Renaissance and this Florentine one at the start was one of the largest and boldest.

The more distinctive work of Brunelleschi in the new manner, however, is to be found in the smaller buildings that he carried on at the same time, such as the Pazzi chapel in the cloister of Santa Croce—the first completed ecclesiastical building of the Renaissance. It is a small structure, some 70 ft. square, containing an open loggia, an oblong main compartment (60 by 30 ft., approximately) and a square chancel with a square sacristy on either side. The loggia is a Roman barrel vault with coffering carried on six lofty Corinthian columns the centre bay of which is larger than the rest and the vault is there carried up on pendentives as a small dome. Above the entablature of the columns the exterior consists of a broad panelled surface and it and the entablature alike are boldly broken by a semi-circular arch joining the two groups of columns. Above this again is an open belvedere under the eaves of an overhanging tile roof and above again the main dome of the chapel. This composition then has no likeness to the façade of a Roman temple although in size it equals many of them. While using elements derived from Rome it is a light and graceful structure in which all the ordered parts of the design are made subservient to the main climax of the great central arch. The same remarks apply to the interior. The construction is very like that of the loggia, a dome intersecting a barrel vault. It is in white plaster, dark stone pilasters and entablatures outlining the architectural forms. Its note, like that of the façade, is lightness and elegance in which Roman forms and details have been used with a new delicacy. In place of the heavy tramp of Romanesque bays and piers we have here a building unified by its central dome and by its orderly arrangement of columns and pilasters, spiritualized and made light and beautiful by the purity of its lines and the delicacy and charm of its detail. It is a new thing neither Roman nor Romanesque, but nevertheless with Roman completeness and unity. The Pazzi chapel has been dealt with at this length because probably more than any other building of its time it gives the Renaissance outlook with its modern feeling for orderliness and perfection combined with the suggestion of Roman grandeur.



Types of Building.—The two chief types of building on which the Italian Renaissance was to found itself were palaces and churches. In mediaeval times the Italian cities were full of lofty stone palaces presenting cliff-like walls to the streets and surrounding central, arcaded courts. They were a feature of Italian urban civilization with its city states. Buildings with flat street façades almost necessarily have an orderly arrangement of windows. To such buildings, therefore, it was easy for the Renaissance architect, thinking in a Roman system of units, based on the regular setting out of colonnades and their super-imposition, to apply his new ideas. The great overhanging eaves of the roof could be transformed to a crowning cornice, the pointed windows turned to semi-circular ones, the rough stonework reduced to a graded system of storeys, gradually approaching a clear ashlar face from which the main cornice could spring. Order was there already. All that had to be done was to introduce a higher sense of unity by seeing that every part bore some tangible relation to the whole. In this way we get palaces like Michelozzi's Riccardi and Majano and Cronaca's Strozzi in Florence in which the strength of the cliff wall is enhanced by contrast with fine detail and a higher sense of unity and power is reached.

The next stage in the development was the actual application to the wall surface of a series of pilasters recalling the Roman system of super-imposed colonnades. These were first used at the Rucellai palace in Florence by Alberti. The columns and their entablatures are here very tentative and are planted on top of the strong stone jointed face, which still dominates. A next step would be the grouping of such pilasters in pairs as at the Palazzo Giraud or the Cancellaria in Rome, both by Bramante. Following this idea through we have, in the more luxurious atmosphere of Venice, columns at each storey taking the place of pilasters and used in great profusion either singly or in pairs with one quarter of their thickness apparently buried in the wall. The palaces on the Grand canal offer many examples, but it will be noticed that even in the richest the wall plane is carefully preserved and the cliff-like face, however articulated, remains. Florentine palaces, however, were never to go beyond applied pilasters until the Baroque period (*see* BAROQUE ARCHITECTURE) arrived. Indeed, it shed even them and produced in the 16th century the astylar palace in which all orders or columns, apart from those to windows or doors, are implicit. A Florentine architect, Antonio Sangallo, carried the idea to Rome with the Farnese palace from whence it has spread over the world.

The architectural quality of orderliness which produced the great palaces and stately churches of the Renaissance did not for a long time, however, destroy the lightness and fancy which the carvers, goldsmiths and painters who turned their attention to building brought to their new task. The smaller details of all early Renaissance buildings, such as wall monuments, balconies and screens in the churches, the furniture in the palaces, show, not only in Florence but in most towns in the north of Italy, a profusion of exquisitely drawn and modelled ornament based on classical motives but used with great freshness and originality. A Renaissance doorway would be applied to, or carved on, a Gothic church, as at Como cathedral, and it would not only form a delightful composition in itself, often in several planes, but would make an extraordinarily rich and delicate piece of decoration against its coarser surroundings. In such work, especially in Lombardy, pilasters and architraves were filled with delicate arabesques. Indeed, in many minds this rich highly carved detail constitutes the chief characteristic of Renaissance work. Those who think this, however, mistake the flower for the tree. The organic relation of all parts to each other and to the whole, based on the Roman system of axial relationship while making use of simple Roman shapes, is the essential trait.

Development.—From Florence the movement of architecture "in the antique manner" spread to every town in Italy and, as in painting, each town produced its school centred round one or two first-rate artists. In Milan, Bramante carried out his early but very accomplished work before Rome absorbed him for St. Peter's. His church of Santa Maria delle Grazie piles up in the simple logical way of applied masses, which the Renaissance always implied, while its detail remains fanciful and in parts Romanesque in character. A great difference between Renaissance architecture in Italy and similar work in France or England is that in the former country the movement attacked from the beginning the plan forms and the structural shape of buildings, whereas in the latter countries it began by an application of the new fashioned detail to buildings which remained Gothic both in plan and structure.

The first half of the 16th century saw the migration to Rome of the best artists from Florence, Milan and other centres attracted by the superior opportunities that city offered under such patrons of the arts as Popes Julius II. and Leo X. Even the sack of Rome in 1527 did not stay building activities. It was there, under the shadow of the great monuments of antiquity, that the full use of the Roman orders (*see* ORDER) was recovered but without any attempt at imitating Roman buildings. This culminating period produced no Parthenon as a climax. The great scheme for St. Peter's, however, started on its career at this time with magnificent and entirely novel plans for the Greek cross building piling up to a great central dome. Bramante laid down the general lines and began the actual structure. Sangallo and Peruzzi followed with modifications of his plan and finally after further vicissitudes Michelangelo took hold of the work and carried it through. His great structure rightly belongs to the Baroque period, though the basic idea on which he worked was that of Bramante and the earlier architects mentioned, and though the building as far as its orderly procession of parts both in plan and section is a Renaissance structure. If, however, St.

Peter's, by the majestic simplicity of its major parts and by its great dome—the best example of the finest architectural invention of the Renaissance—has a claim to a place in that movement it is in smaller buildings in Rome like the Farnese and Massimi palaces, by Antonio Sangallo and Baldassare Peruzzi respectively, that the full flavour of the culminating period is to be tasted. In them is to be found not only complete mastery of plan, by which all apartments flow together to make a whole out of well-shaped units, but both exteriors and interiors that show a similar mastery of classical detail while maintaining the traditional form and expression of an Italian nobleman's house.

From Rome this mastery of classical forms and their adaptation to modern purposes, which makes Italian Renaissance architecture of importance to us to-day, flowed back to the provincial towns. In Bologna, his native city, Peruzzi built a number of astylar houses simple in composition yet completely unified and with detail almost Greek in its refinement. In Verona, Sanmichele, architect and military engineer, fortified the town, his birthplace, and gave to the palaces he built in it and in Venice qualities of strength and scale which are unsurpassed in the works of any master. Through his military engineering work he apparently learnt economy of means in obtaining his effects; for instance, in his series of great gateways through the walls of Verona he reduced cornices to mere bands except in the central portion of his design in order to enforce his climax. His work shows a strength, grandeur and scale that surpasses in its finest qualities Roman work itself. His Grimani palace on the Grand canal at Venice is the strongest and most impressive of those built during the Renaissance.

In the library of St. Mark's at Venice, by Jacopo Sansovino, architect and sculptor, who like so many of his profession started life in Florence, the culminating period of the Renaissance reaches a note of greater richness if not greater grandeur. In its façades of two main storeys, each with fully developed order and arch in the Roman manner, Sansovino succeeded in combining these storeys into one whole by means of an enlarged frieze to the upper order, by low thin steps to the lower and by a crowning balustrade with statues. By the depth of his reveals and the doubling of his subsidiary order in the thickness of the wall, by his overlay of rich, sculptured ornament, he produced here perhaps the richest building before the full advent of the Baroque period. The building, nevertheless, with the assistance of the broad surfaces of its unfluted columns, carries its richness with complete assurance and dignity. There is no feeling that it is overloaded. It is no wonder, therefore, that its façades have formed the main motives of many an opera house and theatre throughout the world, including the most famous, Garnier's great opera house in Paris.

Palladio and Vignola.—The freer use of the orders was carried a step further still by Andrea Palladio who practised chiefly in the small town of Vicenza in the second half of the 16th century but whose name nevertheless became more widely known than that of any of his contemporaries. Indeed, his use in his later buildings of a single order of columns or pilasters as the governing motive for a façade gave rise to the term Palladian in English architecture. So great was his fame, assisted by his book, that Vicenza became a centre of pilgrimage for English architects in the 17th and 18th centuries from Inigo Jones onwards. His written work like that of Serlio, Vignola and other Italian architects who wrote on their art, followed Vitruvius and was largely concerned in establishing a system of proportions for the orders and their accessories. Palladio's buildings, however, are better than his writing. The Palazzo Consiglio, for instance, facing his more famous basilica, where he used a powerful Corinthian order of four columns running up the face of the building, with the cornice returned round each column as in the form of Nerva, shows the hand of the master in the modelling of his small building so that its scale throughout lives up to the giant size set by his columns. In the comparatively poor town of Vicenza to obtain the great effects he sought he was reduced to building in brick covered with stucco and no doubt it was the fluidity of this latter material which gave to his buildings their slight sense of unreality. His stone churches in Venice including the great composition of St. Georgio Maggiore with church, campanile, monastery, harbour and lighthouses in one scheme, facing the town across the lagoon, are sounder architecture because they are sounder building.

Giaconio Barozzi da Vignola, commonly called Vignola, was much the same type of architect as Palladio and, like him, published his designs and his rules of proportion. As Palladio ruled in England so Vignola did in France. Working chiefly in Rome and the neighbourhood during the latter half of the 16th century he stood like Palladio as a bulwark against the increasing power of the Baroque. Michelangelo seems to have little influence upon him, except perhaps in the dramatic quality of his compositions, such as that of his great pentagonal villa at Capzarola and the magnificent climax achieved in his small one for Pope Julius III. in the Borghese gardens.

With these two men, Palladio and Vignola, the work of the Italian Renaissance may be said to have reached the utmost limit of revived and revivified Roman architecture. The motives and orders of the Romans could be exploited no further. For fresh advance it required the genius of Michelangelo and the other founders of the Baroque, who, lifting Italian architecture from its orderly Roman basis of assembled units in plan and elevation, gave it new freedom by considering structure rather as so much plastic material for the fancies of the modeller than so much cubic content in rooms and walls for the imagination of the architect. While, however, the Baroque for a time conquered the known world, with perhaps the single exception of England, as new problems arose in later centuries calling for new solutions the whole of the Western world, including America, turned again to the architecture of the Italian Renaissance, for refreshment, for guidance and, most important of all, for sanity and clearness of expression.

II. RENAISSANCE ARCHITECTURE IN SPAIN

Towards the latter part of the 15th century, the decorative motives of the Italian Renaissance began to make their appear-

ance in the ornamentation of Spanish buildings. The prosperity which followed the conquests of Peru and Mexico and the national exaltation which accompanied the end of the long wars with the Moors had found expression in the construction of great Gothic cathedrals, but for the decoration of these, and especially for the construction of minor works of architecture such as tombs, altars, retablos and rejeria (iron screens), Italian artisans were employed. These artisans, bringing with them many examples of Renaissance design, taught their art to the Spanish and Moorish craftsmen. The patronage of wealthy ecclesiastics who, travelling in Italy on some business of the Church, had fallen under the spell of Italian art, gave an added impetus to this new school of ornamentalists. From the chapels of the cathedrals the new style was introduced into the palaces of the archbishops and into the universities and hospitals established by the Church; the wealthy families of Burgos, Toledo and Salamanca soon adopted it for the decoration of their patios and the façades of their houses; and by the second decade of the 17th century it had become the accepted style of ornament throughout Spain, profoundly modifying the character of Spanish architecture.

Plateresque.—This decoration, which in its delicacy of scale and the exquisite perfection of its workmanship resembles silversmith's work—the work of artisans rather than of architects—has been called Plateresque (from *platero*, silversmith). The motives used are the arabesque, the rinceau, the grotesque, the candelabrum shaft, the panelled pilaster and the richly moulded entablature; and with these Italian forms there are mingled the geometric patterns inherited from the Moors and, not infrequently, Gothic forms such as the pinnacle, the crocket, cresting and the pierced balustrade. Moorish influence is felt, also, in the use of elaborate wood carvings, especially on the ceilings which are splendidly enriched with carved ornament and colour, and in the use of tiles, in superb coloured patterns, for walls and for stairs. Gothic influence survives in the occasional use of the ribbed vault. The use of the undraped human figure is infrequent except in the forms of children, but representations of animals in action, accurately observed and vigorously executed, are used in great profusion. Heraldry is also a source of many ornamental enrichments.

The exuberance of ornament, the fine craftsmanship and the refinement in modelling, in line and in the distribution of light and shade, are the architectural expression of a wealthy and proud aristocracy, which had discovered in Italy a new vocabulary of pleasure-giving forms. These forms were employed, oftentimes, with little understanding of their relation to structure; nor were they used, as in Italy, to give accent and significance to a composition in mass or space. They were used rather to enliven and enrich the textures of walls—an embroidery applied to surfaces—as if the house, or the tomb, were an added garment worn by its owner to express his taste and his importance. Like the costumes of the time, the buildings are embellished with rich patterns, applied with an exquisite tact and with a fine feeling for rhythm and contrast in spacing. The masterpiece of the period is undoubtedly the Ayuntamiento, or city hall, of Seville (1527–35), a building whose ornament is not excelled in Europe in fertility of invention or in facility of execution.

Second Phase.—The Plateresque architecture in Spain resembles the 15th century architecture of Lombardy and Venetia, and, like it, was succeeded by a colder and more monumental manner of building more correctly based upon Roman precedents. This change was due in part to the increasing knowledge of Roman art and to an admiration for the splendid monumental achievements of the 16th century masters, Bramante, Sangallo and Sanmichele, newly revealed to Spain. Her armies had overrun Italy; she had taken, and sacked, the city of Rome itself. But the change is also due to a change in the temper of the Spanish aristocracy. An architecture that was merely an embroidery applied to buildings could not, however lovely in itself, satisfy men who were masters of the world and who desired to express in an enduring form the grandeur and permanence of the political fabric that they had created. The colder and more abstract architecture of ancient Rome, vast in scale and in weight, an architecture, not of ornament but of mass and of proportion, seemed more in keeping with the arrogant imperialism of Charles and Philip.

At any rate when these monarchs had extended their power over Spain, the Empire, Holland, Naples, Burgundy and America, Renaissance architecture in Spain entered, quite abruptly, its second phase. Monumental building succeeded ornamental. Architecture became once more a form-giving art. Buildings seem no longer to have been addressed to the social spirit of man, to seek to charm, to become a pleasing amenity in civic and ecclesiastical life; rather they seem to have been intended to overawe, to express in plastic form the energy and might of a stupendous Government. The palace built by Charles V. at Granada is a fine example of this political architecture. A part of the Alhambra was destroyed to make room for it. One regrets, of course, the oriental palace, full of sensuous charm and aristocratic loveliness, but the newer palace is not less beautiful. Still more impressive is the great Escorial (1560–84), a vast monastery built around a votive church and a mausoleum. This granite pile, which measures 675 ft. by 530 ft., achieves a majestic and awe-inspiring character by sheer size and weight. The grandeur and consistency of the remarkably unified design, the dramatic setting against the mountains and above the plain of Madrid, make of this monument a sublime symbol of the union of Spanish power and Catholic faith. The interior of the great cathedral of Granada, the Lonja, or exchange of Seville, and the hospital of San Juan Bautista, Toledo, are other examples of this second phase of the Spanish Renaissance, which are not unworthy of comparison with the best work of contemporary Italy. This phase did not last long beyond the close of the 16th century. (*See* BAROQUE ARCHITECTURE.)

Churrigueresque.—An architecture more congenial to the artistic spirit of Spain and derived from that of Fontana and Borromini appeared in the early part of the 17th century. It is characterized by a free plastic handling of masses, a broken or undulating skyline, an irregular, capricious distribution of light and shade, and a vast profusion of ornament; structure, geometric form and classic precedent are smothered under a lavish encrustation of luxuriant detail. At times this detail recalls that of the Plateresque; more often it differs from it altogether. It is bolder with far greater depths of broken shadow and vigorous projections; it is more fluid, the forms and planes melting into each other in rounded forms and an intricacy of curved lines; and there is lacking altogether the delicacy of line and shadow and the exquisite refinement in modelling that give distinction to the plateresque. The joyousness, the youth, of the early 16th century was replaced by a self-conscious and sophisticated spirit. Architecture was not, as in the Plateresque, a source of direct sensuous enjoyment; it was a language that attempted to translate passion and mysticism into plastic forms. The vocabulary of this new language is like that of Baroque Italy: there is the same prodigal use of volutes and consoles, of broken and scrolled pediments, of twisted columns, of reversed balusters and of elaborately modelled finials. The cartouche, enmeshed in a fantastic frame of volutes and scrolls, and the human figure, emotionally rendered and set in a niche, are characteristic forms of ornament, and there is a lavish abundance of flowers, of modelled draperies, shells and festoons, often executed (in an altar or retablo) in onyx, lapis lazuli, bronze or some other richly coloured material. This Baroque style in Spain is often called the Churrigueresque, from the name of its most successful practitioner, José Churriguera. It reaches its fullest development in altar-pieces and in the decoration of doorways. The west front of the Cathedral of Marcia, although not completed until the 18th century, is a characteristic example of the Spanish Baroque.

III. RENAISSANCE ARCHITECTURE IN FRANCE

It has become customary to include under the classification of Renaissance architecture all the architecture produced in a country after the Graeco-Roman revival in Italy from the 15th century to the end of the 18th. In the course of three centuries, as must be clear, the types of buildings, their planning and their construction—*i.e.*, all that is vital and fundamental in the character of architecture—must vary widely, to meet the demands of changing social systems; and thus the only characteristic common to such dissimilar types of architecture as, for instance, that of the time of Francis I. and that of the period of 1750, is the employment of the classic orders as elements of the decorative design. Bearing this in mind, then, the following divisions for the periods of French Renaissance architecture are essential:

Renaissance Proper (1475–1610).—Covering the period from the introduction of the Italian-revival classicism through the reigns of Charles VIII., Louis XII., Francis I., Henry II. and his successors, up to 1589, and including, as a transitional period, the period of reconstruction, after the religious wars, of Henry IV. (1589–1610).

Seventeenth Century Renaissance.—Covering the period of the development of French classic art, from its formation in the first half of the century (reign of Louis XIII., 1610–43) through 1660, when the personal influence of Louis XIV. (1643–1715) was dominant, and up to about 1700.

Eighteenth Century Renaissance.—Covering the last phase of the Louis XIV. period, the Regency, and the return, in the second half of the century, to the more academic style which terminated at the Revolution.

Renaissance Proper (1475–1610).—In the last quarter of the 15th century the importations of Italian works of art increased steadily; the French nobles ordered funeral monuments and cabinet work in Italy, and brought over skilled Italian workmen; the military expeditions into Italy had familiarized many Frenchmen with the Italian Renaissance and created the desire to produce at home the masterpieces admired abroad. But the Gothic art (*see* GOTHIC ARCHITECTURE), though dying, was by no means dead, and Gothic edifices continued to be built as late as the 17th century. The Italian influence, therefore, did not find a clear course, but asserted itself simply in the replacement of certain Gothic forms of decoration by Renaissance details. A compromise was thus effected between the old and new traditions, and the work of building went on as before under the guidance of the French master-builders (heads of the various gilds). The plan of a building, and its vaults, high roofs, dormer windows and decorative chimneys followed the Gothic tradition; while on every space suitable for carving appeared the arabesques of the Italian pilaster, the medallions with profiles of the Caesars, and the capitals, mouldings and ornaments inspired by Roman precedent. This dualism of structure and ornament is the essential characteristic of French Renaissance architecture.

Authorship of Buildings.—The authorship of the principal buildings of this first period has been the subject of long and violent controversies; but the argument of those who attribute it almost exclusively to Italian architects is not overwhelmingly convincing. This argument runs to the effect that "the ignorant master-builders whose names appear on the records were incapable of producing the work of the early Renaissance." But these same "ignorant" master-builders had been, and were still, building masterpieces of Gothic architecture. The work of French designers is clearly marked by its *fluency* in the prevailing Gothic construction, and its *uncertainty* in the Italian vocabulary of ornamentation. To ascribe it, therefore, to Italian builders, compels the strange assumption that the Italian, in crossing the Alps, had forgotten the very rudiments of forms of which his knowledge was regarded as authoritative, while acquiring with the same miraculous suddenness a complete knowledge of French Gothic forms!

Buildings.—From the end of the 15th century to the reign of Francis I., the buildings—late Gothic in everything but the introduction of Italian ornamental detail—are the work of a transitional period. Then, in the reign of Francis I., the Gothic elements of the façade were supplanted by new features. As yet there was no clear understanding of the essence of classic architecture, *i.e.*, unity and purity of form, and a definite relationship of all the elements of a composition to a common standard of measure, but there was an effort to attain harmonious distribution of these elements. The king was building, or remodelling, Villers-Cotteret, Fontainebleau, Chambord, Madrid, St. Germain, La Muette and Blois, and, at his example, Renaissance forms were adopted for Écouen, Ancy-le-Franc, St. Pierre at Caen, St. Eustache and St. Étienne du Mont. The nobles, with the necessity for security decreasing as the king's power grew, abandoned their old fortresses or transformed their family seats by large windows pierced in the towers, and by the addition of new wings. The plan of city residences remained Gothic, however, with the master's dwelling standing between the garden and the courtyard in front; the services were arranged at the sides of the courtyard, and the house faced the garden side; this disposition *entre cour et jardin* remained a favourite in France as late as the 19th century. Within the dwelling, the walls—unless covered with tapestries—still showed their masonry, and the rooms still had Gothic timber-work ceilings, but the huge fireplaces were adorned, on their pilasters and niches, with the new arabesques (*e.g.*, chimneys of Blois and Hôtel D'Alluye).

By the middle of the 16th century, the Gothic finally disappeared from domestic architecture, although in religious architecture—where evolution is always slower—the planning still remained flamboyant Gothic (*e.g.*, Brou, Troyes, transepts of Beauvais, and St. Nizier at Lyons). Then, in the period from 1547 to the beginning of the reign of Henry IV. (1589) there was an amazing development—the antique system of proportions was mastered. The use of the Roman orders became general, but they were adapted to conditions so different from those prevailing in Italy that they acquired a character peculiarly French. Such innovations as open stair-wells, alternation of ordinances of pilasters and projecting columnated motives, and the French order of Philibert de l'Orme, are contributions to the architectural repertory that were widely used later. The *giant order*, embracing two storeys, was developed simultaneously in France and in Rome.

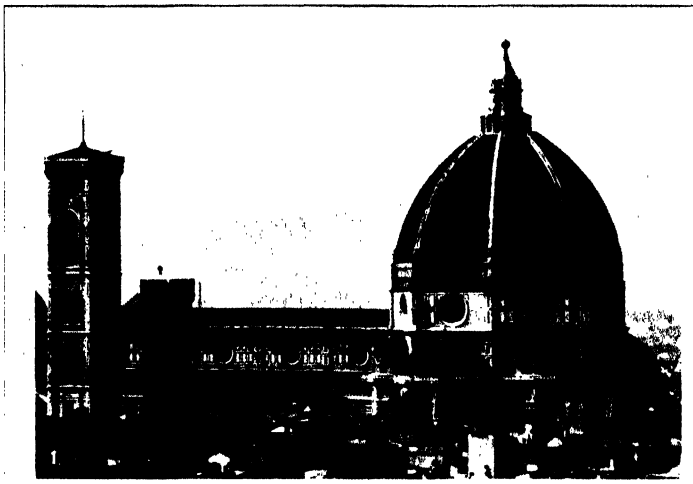
The names of three architects dominate this period: Philibert de l'Orme (1510–70), who built the Château d'Anet, part of Chenonceau and the earliest portion of the Tuileries; Pierre Lescot (1510?–78), who built a portion of the Cour du Louvre; and Jean Bullant (1525–78), who built at Fère-en-Tardenois, at Chantilly (Châtelet), additions to Écouen, and a part of the Tuileries. With the passing of this generation of great architects, the brilliant period closes,—having lasted for only 20 years,—and is succeeded by a period of sterility, due to religious wars and anarchy.

Reign of Henry IV. (1589–1610).—The architecture of the short interval between the time of the entrance of Henry IV. into Paris and his death (1595–1610), may be called the architecture of a reconstruction period. It is characterized by a simplicity and effectiveness attained, not by the use of expensive ornament, but by brick and stone employed in the old French tradition, the façades being decorated by quoins of rustication instead of by the orders—a somewhat severe treatment which was softened by the mellow colour of the walls under the firm silhouette of the slate roofs. The outstanding contribution to architecture, however, was the king's great undertaking to remodel the city, which had grown up haphazardly—an undertaking such as had not been attempted since the days of imperial Rome. To achieve his end, he made laws regulating the heights of buildings and the paving and widening of streets, and prohibiting the overhanging upper stories of the middle ages. Finally, by the contribution of such schemes of civic planning as the place Royale (now the place des Vosges) and the place Dauphine, he inaugurated a school which, after reaching its apogee in the 18th century, furnishes models for city-development to-day. Examples of this period are the important additions to Fontainebleau, the château of St. Germain en Laye and portions of the Louvre.

Seventeenth Century.—At the beginning of the century, there was an unprecedented activity in building; the long period of wars had brought about the usual changes in private fortunes, and the "nouveaux riches" had to provide themselves

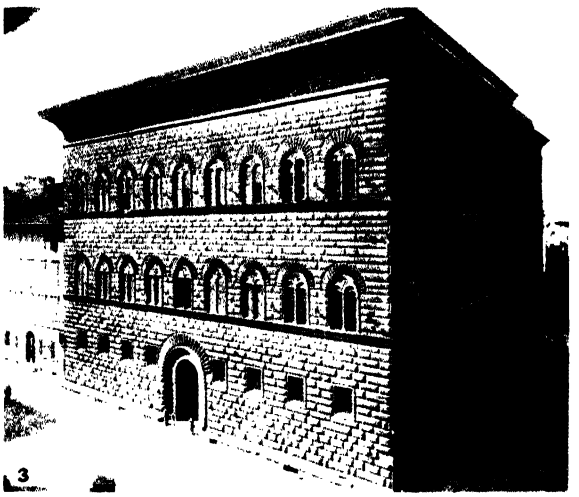
with splendid habitations. The architecture of this time excels in the planning of town residences (hôtels), with their admirable arrangements of the cour d'honneur, service courts and noble garden elevations. The larger houses retained the "galeries" of the earlier Renaissance for the display of art treasures. The country estates are notable for their fine gardens, decorated with statues, basins and balustrades. In ecclesiastical architecture, the Jesuits cast the weight of their influence in favour of the adoption of Renaissance forms, and the churches and chapels designed by members of their order are inspired by the Gesu and the 16th century Italian examples (*e.g.*, St. Paul and the Novitiate in Paris). To the influence of the Jesuit architecture and that of the Italian Baroque, rather than to the Flemish, may be ascribed the exuberant ornamentation prevalent in the early part of the century. Architects of the first rank were numerous, among whom the first is François Mansart (1598–1666), by far the greatest architect of his time, and, according to Blondel (a competent critic of the 18th century), "the most skillful architect France has ever produced." Among other notable works he designed the wing added by Gaston d'Orléans at Blois, with its magnificent stairway, the additions to the Hôtel Carnavalet with their exquisite refinement of detail, the Château de Maisons and the Val de Grâce, a masterpiece which one has only to compare to St. Eustache, built 50 years before, to realize that French architecture had reached maturity. The palace of the Luxembourg, by Salomon de Brosse, the magnificent composition of the town and palace of Richelieu, the chapel of the Sorbonne, by Le Mercier, the Château of Tanlay (Burgundy), by Pierre le Muet, with its beautiful park, antedating the compositions of Le Nôtre, and finally the work of Louis Le Vau, who created the style of Versailles and Vaux-le-Vicomte, of the hôtel Lambert and the collège des Quatre Nations, and who represents the transition from the period of Louis XIII. to that of Louis XIV., are some of the outstanding compositions of the early 17th century.

Louis XIV. Period.—The *grand monarque* placed the artists of his time under a strict administrative discipline. The Académie de France was founded in 1666—five years after the king assumed full authority—and the Academy of Architecture in 1671. There followed a reaction from the empiricism of the preceding period, strengthened by the reverence of the academies for their classic doctrines, and by the king's disdain of foreign influences. The academies were as suspicious of artistic independence as the king of political heterodoxy. The striking feature of this period is a curious contrast between the classic composition of exteriors, free from the earlier experimental fantasies, and the elaborate ornamentation of interiors. There was a simplification both of the masses of a building, and of outward ornament, even to the silhouette of the roofs. The combining of few elements with unerring taste resulted in a stately dignity of proportion that lends even to the most unambitious work in provincial towns the noblesse of the greater constructions. On the other hand, the interiors were often overloaded with decoration. Le Brun, the court painter from 1664 to 1683, was in full authority at Versailles; a great decorator, he had the weaknesses of this aspect of his talent. Thus, refinement and intensity of expression were often sacrificed in the attempt to combine architecture, painting and sculpture into a single homogeneous effect.



Among the principal architects of the time, are Claude Perrault (1613–83), who, besides the Porte St. Antoine, and the Observatoire, designed the three façades of the Louvre which have been praised and attacked beyond all measure, and the excellence of which is readily seen by a comparison with Bernini's project for the same work; François Blondel (1618–86), who designed the beautiful Porte St. Denis; Jules Hardouin Mansart (1646–1708), architect of Marly, the Grand Trianon, Place Vendôme, Place des Victoires and the "Dome des Invalides," and who designed all the work at Versailles after 1676; and Liberal Bruant (1637–97), whose simple, powerful architecture may be seen in the Hôtel des Invalides and La Salpêtrière. A resumé of 17th century architecture would hardly be complete without a mention of Le Nôtre (1613–1700), who brought to its highest development the composition of the formal garden.

Eighteenth Century.—The change that began to make itself perceptible in the last period of the reign of Louis XIV. and up through the first half of the succeeding century, is the further simplification of exteriors, coupled with a still more striking change of interiors. The classic doctrine, with the orders, is still asserted in the designs of the façades; but there appeared a bolder use of blank surfaces, relieved by chains of rustication, and more restraint in the use of mouldings. Thousands of houses of this period are still to be seen, with quiet elevations whose harmonious proportions are their only bid to attract attention, and with skilful interior planning which still serves as a model. The treatment of these 18th century interiors forms a striking contrast with the oppressive splendours of the heyday of Louis XIV. A reaction had set in against the conservatism, and the theatrical pomp of the 17th century, in which people moved like actors on a stage; the new tendency was toward greater freedom in the adaptation of the classic formulas, and lightness and elegance of effect, and *intimacy*. Even at Versailles, stately apartments were broken up into groups of smaller rooms, and houses were planned with corridors and an arrangement of rooms convenient to their uses. The wood panelling, which replaced the marble inlay of palaces or the bare walls of simpler dwellings, was treated as woodwork, with a scale of moulding and decoration suitable to the material and without imitation of stone architecture motives. Fabric and paper were introduced as wall coverings; the ceilings were no longer designed to imitate vaulting—the open beams and joists disappeared and plasterwork was treated frankly as such. The stairways were decorated only by their railings of admirably wrought ironwork. In these interiors there is a complete emancipation from the Greco-Roman decorations of pilasters, cornices, etc.



The examples of the architecture of this period are so numerous that only a few can be mentioned here: *e.g.*, the stables of Chantilly, and the hôtel Biron by Albert, la Malgrange (Nancy) and the hôtel d'Amelot by Boffrand, the Palais Bourbon, by Giardini and l'Assurance. The work of public buildings and city planning counts in its first ranks the admirable ensemble at Nancy (places Stanislas, de la Carrière and du Gouvernement) by Boffrand and Héré de Corny, the bridges at Nantes and Blois by J. J. Gabriel, the place Royale at Bordeaux (Gabriel), and the place Bellecour at Lyons (De Cotte). The religious architecture is exemplified by some imposing monasteries, which acquire with the excellent qualities of the domestic designing a certain touch of worldliness. Examples are St. Étienne at Caen, St. Ouen at Rouen, and the bishops' palaces of Toul, Verdun and Strasbourg.

Second Period.—Madame de Pompadour and her artistic advisers, such as Cochin and M. de Caylus, the archaeologists, and the architects Gabriel and Blondel had never looked with favour upon the infringements of the antique formulas that were committed in the Louis XV. period, and the new discovery of antiquities at Herculaneum and Pompeii infused the supporters of the classic doctrine with fresh conviction. Toward 1750, then, the fashion reverted to the close imitation of a Graeco-Roman style, newly baptized "a la Grecque." De Caylus's *"Recueil d'Antiquités,"* published in 1762, Leroy's *"Ruines des plus beaux Monuments de la Grece"* (1754), Soufflot's work on Paestum, and Piranesi's engravings, encouraged and facilitated the return to antique example by giving more precise documentation. Among the representative works of the architecture of the time are the Petit Trianon, the École Militaire, the wings of the entrance court and the opera at Versailles, and the place de la Concorde, by J. A. Gabriel, the Hôtel-Dieu at Lyon, the church of Ste. Geneviève at Paris, the Pantheon, etc., by Soufflot, and the works of Antoine, Mique, Ledoux, Victor Louis, Rousseau, (theatre of Bordeaux, mint and Palais de Justice at Paris).

IV. RENAISSANCE ARCHITECTURE IN GERMANY, FLANDERS AND HOLLAND

In the 16th century, Germany resisted, more than France or Spain, the Italian influence. The classic spirit in art was apparently less congenial to her civilization, which lacked the Latin basis, and she had not suffered, like France and Spain, the disintegrating influences of a long destructive war which, by weakening the mediaeval and national traditions, had prepared the way for a new and alien art. The Italian motives appeared sporadically—for example, in a Florentine belvedere built in Prague in 1536 and in the Lombardesque wing of the castle at Heidelberg, built in 1556—but the Renaissance had to await the end of the 16th century to win a wide acceptance north of the Alps.

About 1580 the Baroque forms of Alessi were introduced into Germany. These forms, which were understood more as a system of decoration than as elements in mass composition, became immediately popular in the South German cities: broken pediments, scrolls, consoles, cartouches, the human figure placed in a niche, began to appear in profusion on the façades of churches and houses which in composition were still mediaeval. This fusion of Gothic picturesqueness with the sophisticated Baroque ornament gave to this first phase of German Renaissance an altogether unique character. The great stepped gables of town houses and the transept ends or façades of churches, wholly mediaeval in mass and line, flower out at the top into a rich encrustation of modelled form in which all the elements of classic architecture seem to be melted together. Examples of such designs are the Merienkirche, at Wolfenbuttel, the Gewendhaus at Brunswick (1592) and the Pellerhaus, in Nuremberg (1625).

After the Thirty Years' War, which ended in 1648 and devastated the greater part of the Rhine countries, German Renaissance architecture entered a new phase. The Baroque spirit gained a more complete ascendancy and in many localities mediaevalism entirely disappeared. Naturally the Baroque was more completely accepted in the southern and Catholic countries where Italian architects, brought into Germany by the Jesuits, built, or helped to build, many churches and palaces. Along the Rhine the French influence was felt, but it was not until the 18th century (*see* Modern Architecture: *18th and 19th Centuries*) that Germany turned directly to France for artistic inspiration. In that century the architecture of Versailles was widely imitated in the German courts, achieving there a compromise, or fusion, with the Italian Baroque. The result was a vigorous and original style, often piquant and full of that element of "surprise" which is a result of Baroque freedom and movement.

Germany, having a larger number of capital cities—there were more than 300 in the 16th century—developed a greater variety of local styles than any other country. Vienna was of course the most important centre. The relief that was felt when in 1685 the Turks were driven from before her walls, the prosperity fostered by Leopold I. and Charles VI., and the renewed faith of the Catholic reaction, found expression there in a series of remarkable monuments. Fischer von Erlach and Lukas von Hildebrandt, the two great architects of Vienna, transformed the mediaeval city, as Bernini had transformed Rome, with fountains and public places, with majestic churches, vast palaces and astonishing gardens. In their hands the exuberant Baroque, touched with an oriental fantasy, reached a magnificence altogether consonant with the gorgeous imperialism and the fervid piety of the times. The Karlskirche (1717–37) and the Hofbibliothek (1736), by von Erlach, and the Belvedere (1713–16), by Hildebrandt, are the most famous and perhaps most characteristic examples of this Viennese Renaissance.

After Vienna, the smaller courts of Dresden and Munich furnished important opportunities for the Renaissance architect. In Dresden, Pöpplemann (1662–1736) built the court of the Zwinger palace (1711–22), an extraordinary assembly of fantastic pavilion, bizarre planting and agitated sculpture. The Frauenkirche, in Dresden (1726–43), by George Bähr, is an original, free and virile design, perhaps the greatest achievement of the German Renaissance. In Munich, where the Italian architect Agostino Barelli had built a Neapolitan church, the Theatinerkirche (1667–75), the Wittelsbachs employed the French architect, François Cuvilliers, to add to their somewhat grandiose palace the altogether delightful Residenz-theatre (1752–60). Salzburg, with its cathedral (1614–34), its University church, and its Mirabel-Schloss, is one of the loveliest of Baroque towns; Prague has the great Wallenstein palace (1673–1730), the work of the Italian Marini, as well as the more Teutonic Kinsky palace, the work of the talented architect Kilian Ignaz Dientzenhofer; and in Potsdam, where, under Frederick the Great, French influence is most felt, the palace of Sans Souci (1716) achieves a delicacy and graceful freedom certainly not excelled in contemporary France.

To this architecture of the city and court there is added the architecture of the monasteries. Placed picturesquely among the hills of the Danube or the Rhine, these vast buildings offered opportunities most congenial to the spirit of 17th century architecture. Melk (1707–36) is perhaps the most impressive; a colossal mass which commands the Danube from the top of a mighty cliff and throws against the sky a superb tangle of modelled spire and dome.

In Flanders and Holland the development of architecture in the Renaissance was not essentially different from that of North Germany. The Jesuit influence was felt in Flanders and the development of churches of the Il Gesu type, such as the church of St. Michael, in Louvain (1650) was parallel to the contemporary development in South Germany and France. In Holland, as in Germany, the stepped gables of the town houses were transformed by the addition of Baroque detail but the use of brick and of quoins and the need of economy often gave them a more sober aspect than their Germanic cousins. At times the French influence was felt, as, for example, in the Hôtel de Ville in Antwerp (1561), a design in which superimposed columns enframe round-arched windows with a gracefulness and distinction in detail that recalls the work of Lescot

V. RENAISSANCE ARCHITECTURE IN ENGLAND

The Renaissance architecture of England may be conveniently divided into two phases which correspond roughly to the 17th and 18th centuries, to the period of the Stuarts and the period of the Georges. In the first phase the genius of two great architects, Inigo Jones and Christopher Wren, created for England a new system of design, based upon elements imported from Italy. In the second phase a host of other architects, highly talented but less original, imitated and developed the architecture formulated by Jones and Wren. The 17th century supplied a mine of architectural motives and enriched England with a few supremely great masterpieces; the 18th century made use of that mine to create a great number of brilliant designs, no one of which quite achieves greatness. (*See* Modern Architecture: *18th and 19th Centuries.*)

There are not lacking in England many examples of the use of Renaissance forms before the 17th century, but the spirit of her architecture remained essentially mediaeval. In the Tudor period, when the cathedral-building impulse had come to an end, when the monasteries ceased to exist and when the building of great country houses had become the chief preoccupation of architects, there grew up a certain simplicity and breadth of handling, a horizontal tendency in composition, which presaged the Renaissance. At the same time the ornamental motives of Italy appeared on the mantelpieces and around the doorways of the Elizabethan houses; and the craftsmen of Flanders, then numerous in England, employed these motives in their decorative work in plaster or carved wood.

Inigo Jones.—The failure of the national style of England to resist the imported Italian style is one of the remarkable

circumstances of Renaissance architecture. Travel in Italy, where the cultivated Englishman might compare the masterpieces of Bramante and Michelangelo with the formless Tudor of his own land, and the importation of Italian books, prepared the way no doubt for the new architecture, but they do not explain its immediate success. That success appears to have been due to the genius and force of one man: Inigo Jones. Jones, almost single-handed, put an end to the mediaeval tradition and set up a national movement that rescued English architecture from the Tudor chaos and brought it back to the Roman road along which progress was possible. His supreme accomplishment was to revive in England the conception of architecture as a form-giving art, having an academic and intellectual basis, and to get this accepted as the foundation of a new, national development.

This conception of architecture, rigorously developed by the somewhat intransigent architects of the 18th century, brought into English architecture a certain artificiality which is no doubt the cause of much that is deplorable in the English tradition. A lack of vitality and saliency results when architecture becomes, as it did in Georgian England, a wholly academic art, when the authority of books and of the Italian masters replaces a tradition in building to which the usages of the people, the needs of institutions, the climate and the temper of the nation have contributed. Nor did England develop great sculptors and mural painters to soften, as in France, the austerity of the Roman column and vault. The traditions of fine craftsmanship in plaster and in wood carving remained but they did not suffice to give English Renaissance architecture the warmth, the feeling of having become wholly assimilated, wholly expressive of a national temperament, that one finds in the Renaissance of Italy or Spain.

The reputation of Inigo Jones rests in no small degree on the designs that he made for the great palace at Whitehall in the years 1619–25. This palace is comparable in size to the great projects of the Louvre and the Vatican. The design is splendid and monumental and the palace, had it been erected, would without doubt have been unrivalled, except perhaps by the Escorial, in grandeur of effect. The façades of its seven courts abound in original motives, in which Palladian architecture is skilfully made comformable to English needs. In this, as in all his designs, Jones displays the correctness in proportion and the vigorous and unaffected handling of space and detail, that give his style a nobility and strength excelling that of any other English architect. The Banqueting hall, which is the only part of the palace of Whitehall actually executed, is an embodiment of these qualities.

Christopher Wren.—On the foundation laid by Jones, Sir Christopher Wren built the great masterpieces of English architecture. To the strength and sensitive feeling for proportion possessed by Jones, he added one of the most active and resourceful imaginations in the history of architecture. To a solid basis of Palladianism—that is to say, to correctness in academic design—Wren added the freedom and movement, the piquancy and drama, of the Baroque. He could unite in one ensemble the two currents into which architecture had divided in the 17th century, the academic and the ingenious, so that they flowed together into a reservoir of original and expressive motives that the 18th century was to find inexhaustible. Very characteristic of this compromise are the 51 parish churches that Wren built in London after the great fire of 1666. Among his secular buildings are important additions to Hampton Court, the library of Trinity college, Cambridge, and the great hospital at Greenwich.

In the city churches Wren created a wholly new type. Built for congregational use, with galleries, shallow chancels and meagre provision for services, they occupy irregular congested sites in the midst of crowded streets. The exteriors had to be severely plain, since funds were scarce; red brick and plaster for the interior were the materials employed. Yet with all these discouragements Wren produced interiors oftentimes full of charm, and exteriors that play a commanding part in their civic environment. These exteriors, plain and even box-like, have slender towers so placed as to be most effective in the street-picture and modelled at the top into delicate spires or lanterns over which there is an encrustation of classic forms.

The secular buildings were more conventional in character, The additions made to Hampton Court (*c.* 1690) constitute a sober essay in brick-and-stone architecture, somewhat crowded in effect and lacking the repose that marks their Italian prototypes. The Cambridge library (1678) follows the lines of the library at Venice, but is without the piquant proportion and wealth of sculptured ornament that give the Venetian façades so much distinction and grace. Greenwich hospital is more imaginative, having a masterly plan in which four palatial masses are grouped on an axis about two courts. Two domed pavilions are introduced to give the design unity and add life to the façades.

All of these buildings, although exceedingly diverse and original, are of less importance than the great cathedral of London. The ruins of the Gothic cathedral having been cleared away after the Great Fire, Wren was commissioned in 1668 to construct a new St. Paul's in accordance with a Renaissance design that he submitted. During the period from 1675, when the first stone was laid, to 1710, when the work was completed, Wren made many departures from this accepted design, which grew steadily in imaginative power and monumental unity, but at no time did he abandon his central idea, a classic monument contrasted with forms taken from the Baroque. The greatness of St. Paul's is derived, not from the perfection of detail, which is frequently open to criticism, but from the consistency and grandeur with which it realized this idea. The central dome, definite and geometric in mass and in silhouette, imposing in scale, rises from a wide podium and is preceded, at the western end, by two spirited campaniles whose modelled surfaces, profuse shadow and broken silhouette contrast dramatically with the simpler forms with which they are associated.

Eighteenth Century.—After the death of Wren there remained the academic basis which Jones had established for English architecture and the compromise which Wren had brought about between the Palladianism and the virile and free Baroque. These two traditions dominated English architecture and gave direction, in more or less equal degree, to its development during the 18th century. But gradually the academic triumphed. The largeness of conception, the grandiose effect, is forsaken towards the middle of the century in favour of purity and repose.

John Vanbrugh (1666–1726), who did not begin to practice architecture until after the age of 35, was the most robust and daring of Wren's successors and most resembled him in the power and breadth of his imagination. He was the builder of vast country houses, such as Blenheim (1710), 856 ft. long, and Castle Howard (1702), a private dwelling with a dome 100 ft. high. These are monstrous buildings, with innumerable faults of technique and propriety, but magnificent in conception, piling up huge geometric masses around the perimeters of immense courts in a kind of intoxication of architecture.

Nicholas Hawksmoor (1661–1736), a pupil of Wren and an assistant of Vanbrugh, found fewer opportunities than either. For his fine Christ church, Spitalfields, he combined the most original and spirited tower in England with an interior almost unrivalled in formal elegance and classic beauty. The façade that he built for Westminster Abbey is more successful than might have been expected from an age so out of tune with the mediaeval spirit. His rugged and simple work contrasts strangely with that of his more successful and versatile contemporary, James Gibbs (1682–1754). Gibbs, like Hawksmoor, a builder of churches in the Wren tradition, shows great facility in adapting and developing motifs taken from Wren; but his care for correct detail and for elegance in technique oftentimes lessens the breadth and virility of his work. The church of St. Mary-le-Strand, in London, is a good example of his style. The Radcliffe library, Oxford, is a more monumental building, but executed with less *address*. St. Martins-in-the-Fields, London, has a magnificent spire thrust through the roof of a Roman portico; a conception worthy of the greatest Baroque designers, boldly carried out and combined with an interior full of dignity and feeling.

Gibbs was a scholarly architect, possessing that thorough training in Palladian design which is characteristic of the 18th century designers, but he found in Wren a source of vitality which counter-

DECORATIVE DETAILS OF THE RENAISSANCE

1. "The creation of Adam and Eve and their expulsion from Paradise," a panel in bronze by Lorenzo Ghiberti (1378–1455) in the famous east door made for the Baptistery in Florence between 1425 and 1452, a masterwork of early Renaissance decorative sculpture
2. Vault of the Scala d'Oro in the Doges' Palace, Venice, designed by Jacopo Sansovino (1486–1570)
3. Glazed polychrome terra cotta, "Assumption of the Virgin" by Luca della Robbia (1400–82), characteristic of the early Florentine Renaissance in its perfect blend of architecture and sculpture as well as in the exquisite delicacy of its modelling. In the Metropolitan Museum of Art, New York
4. Swiss room, 17th century, the woodwork characteristic in its free handling of Baroque motives. Now in the Berne Museum
5. Swiss panelled room, 17th century, with rich Baroque woodwork and a magnificent porcelain stove. Now in the Metropolitan Museum of Art, New York
6. The seat for the Archbishop of Canterbury incorporated in the choir stalls of St. Paul's cathedral, London, executed by the wood carver Grinling Gibbons (1648–1720) in collaboration with the architect Sir Christopher Wren (1632–1723). It is characteristic in its dignified combination of restrained Baroque forms with figures, heads and naturalistic foliage

APPLIED ARTS OF THE RENAISSANCE

1. Halberds: left, German, 16th century, characteristic in its fine decoration on the surface of the metal; right, Italian, 16th century, showing greater amount of modelling in the round and strong Baroque elements. 2. Louis XIV. tapestry, French, of the last half of the 17th century, showing the return of the Sabine women with the Roman soldiers; probably one of a set woven at the royal looms of the Gobelins. 3. Embroidered Italian altar frontal, with touches of naturalistic ornament, in the manner of Louis XIII. and early Louis XIV. textiles. 4. A three-quarter suit of Italian armour, etched and gilded, and showing the arms of the Barberini family, probably once the property of Taddeo Barberini, middle 17th century. It illustrates the lavishness of ornament applied to arms and armour in the Baroque period. 5. French Renaissance helmets: on the left, period of Henry II., showing the strong classic influence; on the right, period of Louis XIV. with typically fantastic outline. 6. French silk brocade of about 1700, showing a characteristic Louis XIV. mixture of Baroque line and naturalistic detail. 7. A dagger and scabbard, dated 1567, of Swiss manufacture

acted, to some extent at least, the frigidity of the master of Vincenza. Gibbs' contemporaries were often less fortunate: Lord Burlington, a wealthy amateur whose actual accomplishments are still a subject of controversy; Colin Campbell (d. 1734), his protégé and the author of the *Vitruvius Britannicus;* and William Kent (1684–1748), who resided in Burlington House, form a group of academic architects to whom adherence to the Italian model seemed more to be desired than individuality of manner or a continuation of the English tradition of Wren. All were builders of great country houses.

Kedleston Hall, by James Paine (1716–89), recovers to some extent the spirit of Vanbrugh, speaking the language of abstract architectonic form, rather than that of ornament. It is planned in the grand manner, with a porticoed central block flanked by smaller blocks, in which all the parts echo those of the centre. On the major axis are two Roman rooms, one peristyled and one domed. Harewood House, Yorkshire, by Carr of York (1723–80), in which there is, as at Kedleston, a central block flanked by wings, illustrates further the rigid purity of the classic taste of the middle of the century, when the tradition of Wren was disappearing and correct proportion was allowed to take the place of inspiration. The Palladian bridge at Wilton, by Robert Morris, and the house at Prior park, Bath, by John Wood, are other examples.

The last of the Renaissance architects were William Chambers (1726–86) and Robert Adam (1728–92). To the former fell the greatest opportunity of the century, the building of the immense Somerset palace in London. A man of pure taste and of unusual executive powers, he succeeded in creating one of the finest palatial façades in Europe; a façade, however, which has the excellence of scholarliness and of technique rather than that of inspiration and power. Adams, who practised in partnership with his brother James, was even more academic in his outlook; his style is, on his exterior designs, simple, tenuous and dry in the extreme. His interiors, which often take unusual shapes in plan and in the modelling of ceilings, are enriched by a delicate and graceful system of decoration which, when skilfully executed, attains a unique loveliness. His influence was enormous and under his leadership the architecture of the Renaissance came to an end.

RENAISSANCE ART. The revival of classic learning in Italy, which was so marked a feature of Italian culture during the 15th century, was paralleled by an equal passion for the beauty of classic design in all the artistic fields; and when this eager delight in the then fresh and sensuous graciousness that is the mark of much classic work—to the Italians of that time, seemingly the expression of a golden age—became universal, complete domination of the classic ideal in art was inevitable.

This turning to classic models was less sudden and revolutionary than it seemed. Throughout the history of Romanesque and Gothic Italian art, the tradition of classic structure and ornament still remained alive; again and again, in the 12th and 13th centuries classic forms—the acanthus leaf, moulding ornaments, the treatment of drapery in a relief—are imitated, often with crudeness, to be sure, but with a basic sympathy for the old imperial Roman methods of design. (*See* GOTHIC ART; ROMANESQUE ART.) How much more at home seems the mediaeval Italian artist, who carved the spiralling acanthus leaves on the doors of Pisa cathedral (11th century) than the designer of the laboured and stupid, crocketted capitals of the cathedral in Florence (14th century), or the contorted and unconvincing buttress pinnacles of Milan cathedral (begun 1386). The best of Italian Gothic art is always that which is least like northern Gothic, and is usually dominated by ideals, essentially those of earlier Italian building, like the Byzantinesque palaces of Venice. Niccolo Pisano (*c.* 1206–1280) was but the first of many Italian artists, particularly sculptors, to turn definitely to Roman sculpture for inspiration.

It was therefore only natural that Brunelleschi (1377–1476) should study the ruins of ancient Rome, and that, following his example, the whole artistic world of Florence turned to the same source of inspiration almost unanimously. Brunelleschi's famous cupola over the cathedral of Florence completes the work of the preceding age and is not yet a Renaissance manifestation. The new style was displayed in the Pazzi chapel and in the plans for San Lorenzo and San Spirito.

Florence was the great centre of this early Renaissance; whence it spread throughout Italy in the 15th century; the greater number of artists were Florence-trained. The enthusiastic patronage of art of the new type by Cosimo dei Medici (1389–1464), and Lorenzo dei Medici (1449–1492), who founded the famous Platonic Academy, gave a tremendous impetus to the movement, and the general Florentine method of art training, through *bottege,* or craftsman shops, assured the fact that the Renaissance was not confined to architecture and sculpture, but spread to all the industrial arts as well.

Another element besides the influence of ancient Rome becomes evident as the Renaissance matured in such of the minor arts as textiles, pottery and metal work. This was the influence of the Near East. Commerce between Italy and the Turkish dominions was constant and large in amount; and Oriental pottery and textiles were much sought after. When the Italians started manufacturing their own goods to compete with this foreign source, limitation and adaptation of the Oriental patterns was natural. Thus the controlling designs of Venetian velvets and brocades, down to the 18th century, owe much to the carnation and the palmette of Persia, and in 16th and 17th century armour and silver-ware, there occur the spear-head shapes and bifurcated leaves and intricate interlaces of fine lines which characterize the inlaid brass, copper and steel of Damascus or Constantinople.

By the beginning of the 16th century the tentative and experimental characteristics of the earlier Renaissance had, in Italy, given way to the mature, knowing, and facile use of classic forms which constitutes the High Renaissance or cinquecento (*q.v.*). In architecture, the orders were used with entire command; in the minor arts the decorative exuberance of the 15th century was yielding to sounder and more dignified conceptions. Yet the development of this polished classicism was limited and eager; creative imaginations refused to be bound by it. The result was the resurgence of untrammelled and, at times, unlicensed individualism in design, which is known as the Baroque or late Renaissance. Already, in the work of Michelangelo, 1474–1564, and Cellini, 1500–71 (*see* SILVERSMITHS' AND GOLDSMITHS' WORK), Baroque elements are obvious, and by the year 1600 the ideals of climax, broken curves, magnificent composition and dynamic contrasts, which constitute the Baroque movement, were universally accepted, and the classic forms became merely an inspirational frame-work for individual development and creation. The Baroque was a style curiously turgid, often gigantesque, theatrical, often denying or falsifying structural frame-work, yet magnificently alive; producing alike such over lavish and ill considered decorations as those of Andrea Pozzo (1642–1709) for the church of S. Ignazio in Rome and the dignified and monumental colonnades of the Piazza of S. Peter's, by Bernini (1598–1680). During the 18th century the vitality of the Baroque degenerated into a chaos of contorted forms, to be in turn replaced, at the end of the century, by a recrudescence of stern, cold and rather sterile classicism. Yet the Renaissance in Spain was no mere copy of the Italian.

Renaissance feeling was introduced into Spain during the latter years of the 15th century by wandering Italian sculptors, but a school of native artists soon developed, and during the 16th century an individual school of Renaissance dominance was complete, despite the Italian impetus given by the campaign of Charles V., 1500–58, and the fanatical Romanism of his son Philip II., 1527–1598, whose palace monastery, the Escorial, by Juan Bautista (16th century) and Juan de Herrera (1530–97), is a stark and lonely monument to Philip II.'s Italian taste. Else-

where, the Moorish influence was so strong as to modify the Italian forms profoundly; Moorish craftsmen controlled the potteries and often built the buildings. Moreover, perhaps due to the bleak and sombre character of so large a part of the Spanish territory, the emotional quality of the Spanish Renaissance work has a sharp pungency quite different from the usual graciousness of the Italian feeling. The style in Spain may be divided into three parts—the early Renaissance, or Plateresque (*q.v.*), in which Moorish influence is marked; the classic or Griego-Romano, a short and sterile attempt to introduce strict Italian classicism; and the Baroque or Churrigueresque, so-called from one of its main exponents, Jose Churriguera (died 1725). It was in this final style that the Spanish temperament found itself most at home. Particularly characteristic of the Spanish Renaissance is the work in certain of the minor arts, especially in iron work, as shown in the magnificent church screens, or rejeria (*q.v.*); in furniture, in which iron and wood were frequently combined; and in stamped leather, for which Spain was famous.

In France, the history of the early Renaissance shows a style originally essentially an imported court fashion, gradually permeating all French life. The Italian campaigns of Charles VIII., 1470–1498, Louis XII., 1462–1515, and Francis I., 1494–1547, had given the French court an intimate knowledge of the comparative luxury, cleanliness and monumentality of the Italian cities. Italian artists were invited to the court; Italian decorators and architects helped Francis I. in his great building schemes. Yet this court fashion had to compete with a vivid and vital flamboyant, late Gothic style, and much of the charm of the early French Renaissance results from the naive, yet brilliantly executed combinations of the two influences. During the reign of Henry II., 1519–1559, the classic ideal was dominant, though Gothic forms were still in use. Under Henry IV., 1553–1610, though the Gothic had at last passed away, Baroque freedom controlled design, and under Louis XIII., Louis XIV., Louis XV., and Louis XVI. whose reigns stretched from 1610 to 1793, there was a continual see-saw between academic classicism and imaginative freedom. (*See* Louis Styles.)

From the beginning a court style, the French Renaissance remained essentially a luxurious style. All of the arts of luxury flourished. Rich textiles—tapestries and brocades—are characteristic, and the lavish furniture was copied all over Europe, especially during the 18th century. The development of pottery, first privately, and later under government auspices, culminated in the magnificent porcelains of Sèvres.

The development of the Renaissance in the rest of Europe was marked by common features. In England and the Teutonic countries, there was not only a late vital Gothic style, but definite characteristics of national taste and vastly different climatic and geographical conditions. Yet the humanistic impetus of the Renaissance existed almost everywhere and the beauty of the naturalistic painting and sculpture, as well as the exquisite productions of Italian goldsmiths, formed a continual invitation toward a change in artistic ideals. Thus, despite occasional purely classic work by Italian artists, such as Torregiano's tomb of Henry VII. in Westminster Abbey, London (1515), the early Renaissance in north Europe is chiefly characterized by the gradual creeping in of misunderstood classic decorative forms, often caricatured. In none of these countries did classicism become dominant until the 17th century, and even then it is coloured by local taste. Thus in Germany, the picturesqueness of late Gothic decorative design controlled all of the arts down to the 18th century and even the pseudo-classic of the French inspired Rococo embodied many picturesque elements. In England, due to the influence of Inigo Jones, 1572–1652, and Sir Christopher Wren, 1632–1723, at least in architecture, classic forms were used with purity and unusual correctness. In Germany and Flanders, on the other hand, Baroque elements were favoured, especially in woodcarving and the minor arts generally; and through the diffusion of Flemish craftsmen consequent upon the confused religious and political conditions during the 17th century, these northern varieties of Baroque forms were broadcast over Europe, influencing markedly the later Renaissance work in England and recognizably, though to a less extent, that of France and Spain.

This confusion of international influences marked the Renaissance of the 18th century, the style movements in France being generally paralleled by those in other countries. Yet the erratic swing between license and classicism was indicative of a decaying style vitality, and new archaeological discoveries were giving to the classicism of the end of the century a motivation quite different from the simpler Renaissance tradition that was dying. With the fall of the French court, in the French revolution, more than a political system was swept away, for with it went the last vestiges of Renaissance tradition. *See* Baroque Architecture; Bronze and Brass; Interior Decoration; Painting; Potteries and Porcelains; Renaissance Architecture; Rococo, Louis Styles; Rugs and Carpets; Silversmiths' and Goldsmiths' Work; Tapestry. (T. F. H.)

RENAIX, town, province of East Flanders, Belgium, 8 m. S. of Oudenarde, at the foot of the hills of Flanders. It has yielded many pre-Roman and Roman finds. There are manufactories for woollen and linen goods. Pop. (1925), 22,669.

RENAN, ERNEST (1823–1892), French philosopher and Orientalist, was born on Feb. 27, 1823, at Tréguier. His father's people were of the fisher-clan of Renans or Ronans. He was only five years old when his father died, and his sister Henriette, twelve years older than Ernest, a girl of remarkable character, was henceforth morally the head of the household. Ernest was educated in the ecclesiastical college at Tréguier. In the summer of 1838 he carried off all the prizes at the college. Through his sister, who was teaching in Paris, Dupanloup heard of him, and sent for him at once, and placed him in the new ecclesiastical college of St. Nicolas du Chardonnet. He then proceeded to study for the priesthood at the Seminary of Issy, then at St. Sulpice, and finally he found his way to Stavistas, a lay college of the Oratorians. He soon found himself torn between his desire to lead the life of a Catholic priest and his intellectual inability to accept in its entirety the ordinary presentation of Catholic doctrine, or to submit to ecclesiastical authority. Even at Stavistas he found himself too much under the domination of the Church, and, after a few weeks there, he reluctantly broke the last tie which bound him to the religious life, and entered M. Crouzet's school for boys as an usher. There he made the acquaintance, in 1846, of the chemist Marcellin Berthelot, then a boy of eighteen. To the day of Renan's death their friendship continued. Renan was occupied as usher only in the evenings. In the daytime he continued his researches in Semitic philology. In 1847 he obtained the Prix Volney for his "General History of Semitic Languages."

The revolution of 1848 confronted him with the problems of Democracy. The result was an immense volume, *The Future of Science,* which remained in manuscript until 1890. *L'Avenir de la science* is an attempt to conciliate the privileges of a necessary *élite* with the diffusion of the greatest good of the greatest number. In 1849 the French government sent him to Italy on a scientific mission. In Italy the artist in him awoke and triumphed over the savant and the reformer. On his return to Paris Renan lived with his sister Henriette. A small post at the National Library, together with his sister's savings, furnished him with the means of livelihood. In the evenings he wrote for the *Revue des deux mondes* and the *Débats* the exquisite essays which appeared in 1857 and 1859 under the titles *Études d'histoire religieuse* and *Essais de morale et de critique.* In 1852 his book on *Averroès* had brought him not only his doctor's degree, but his first reputation as a thinker. In his two volumes of essays Renan shows himself a Liberal, but no longer a Democrat. Nothing, according to his philosophy, is less important than prosperity. The greatest good of the greatest number is a theory as dangerous as it is illusory. Man is not born to be prosperous, but to realize, in a little vanguard of chosen spirits, an ideal superior to the ideal of yesterday. Only the few can attain a complete development. Yet there is a solidarity between the chosen few and the masses which produce them; each has a duty to the other. The acceptance of this duty is the only foundation for a moral and just society. The aristocratic idea has seldom been better stated.

Renan now began to frequent more than one Parisian salon, and especially the studio of Ary Scheffer, whose niece and adopted daughter, Cornélie, he proposed to marry in 1856. Henriette consented not only to the marriage, but to make her home with the young couple, whose housekeeping depended on the sum that she could contribute. The history has been told by Renan in the memorial essay, *Ma Soeur Henriette*. In 1859 appeared his translation of the *Book of Job* with an introductory essay, followed in 1859 by the *Song of Songs*.

Renan was now a candidate for the chair of Hebrew and Chaldaic languages at the Collège de France. The Catholic party, upheld by the empress, would not appoint an unfrocked seminarist, a notorious heretic, to a chair of Biblical exegesis. Yet the emperor wished to conciliate Ernest Renan. He offered to send him on an archaeological mission to Phoenicia. Leaving his wife at home with their baby son, Renan left France, accompanied by his sister, in the summer of 1860. Madame Renan joined them in January 1861, returning to France in July. The mission proved fruitful in Phoenician inscriptions which Renan published in his *Mission de Phénicie*. They form the base of his *Corpus Inscriptionum Semiticarum*. At Amshit, near Byblos, Henriette Renan died of intermittent fever on Sept. 24, 1861. Her brother, himself at death's door, was carried unconscious on board a ship waiting in harbour and bound for France. On Jan. 11, 1862, the Minister of Public Instruction ratified Renan's election to the chair of Hebrew. But his opening lecture, in which, amid the applause of the students, Renan declared Jesus Christ "an incomparable Man," alarmed the Catholic party. Renan's lectures were pronounced a disturbance of the public peace, and he was suspended. He refused the librarian's post he was offered in exchange, and thenceforth lived by his pen.

Vie de Jésus.—Henriette had told him to write the life of Jesus. They had begun it together in Syria, she copying the pages as he wrote them, with a New Testament and a *Josephus* for all his library. The book is filled with the atmosphere of the East. It is the work of a man familiar with the Bible and theology, and no less acquainted with the inscriptions, monuments, types and landscapes of Syria. But it is scarcely the work of a great scholar. Renan still used his literary gifts to pursue a scientific ideal. He produced the *Apostles* in 1866, and *St. Paul* in 1869, after having visited Asia Minor with his wife. His object was "to evoke from the past the origins of Christianity." In *St. Paul*, as in the *Apostles*, Renan shows his concern with the larger social life, his sense of fraternity, and a revival of the democratic sentiment which had inspired *L'Avenir de la science*.

The Franco-German War was a turning-point in Renan's history. Germany had always been to him the asylum of thought and disinterested science. Now his heart turned to France. In *La Réforme intellectuelle et morale* (1871) he endeavoured at least to bind her wounds, to safeguard her future. At the same time the irony always perceptible in his work grows more bitter. His *Dialogues philosophiques*, written in 1871, his *Ecclesiastes* (1882) and his *Antichrist* (1876) (the fourth volume of the *Origins of Christianity*, dealing with the reign of Nero) show a disenchanted and sceptical temper. Gradually he aroused himself from his disillusioned mood, and observed with genuine interest the struggle for justice and liberty of a democratic society. The fifth and sixth volumes of the *Origins of Christianity* (the *Christian Church* and *Marcus Aurelius*) show him reconciled with democracy, confident in the gradual ascent of man.

Later Works and Death.—In 1883 he published *Souvenirs d'enfance et de jeunesse*, which have the Celtic magic of ancient romance and the simplicity, naturalness and veracity prized in the 19th century. But his *Ecclesiastes*, published a few months earlier, his *Drames philosophiques*, collected in 1888, give a more adequate image of his fastidious, critical, disenchanted, yet not unhopeful spirit. They show the attitude towards uncultured Socialism of a philosopher liberal by conviction, by temperament an aristocrat. We learn in them how Caliban (democracy), the mindless brute, educated to his own responsibility, makes after all an adequate ruler; how Prospero (the aristocratic principle, or, if we will, the mind) accepts his dethronement for the sake of greater liberty in the intellectual world, since Caliban proves an effective policeman, and leaves his superiors a free hand in the laboratory; how Ariel (the religious principle) acquires a firmer hold on life, and no longer gives up the ghost at the faintest hint of change. Religion and knowledge are as imperishable as the world they dignify. Thus out of the depths rises unvanquished the essential idealism of Ernest Renan.

At sixty years of age, having finished the *Origins of Christianity*, Renan began his *History of Israel* (3 vols., 1887–91) based on a lifelong study of the Old Testament and on the *Corpus Inscriptionum Semiticarum*, published by the Académie des Inscriptions under his direction from the year 1881 till the end of his life. He died on Oct. 12, 1892.

There is no collected edition of Renan's works. There is an English translation of the *Vie de Jésus* in Everyman's Library (1927). His *Correspondance* has been edited in 2 vols. (Paris, 1926–28). For Henriette Renan *see* Prof. Giraud, *Soeurs de grands hommes* (1926) and Renan's *Lettres Intimes* (1923).

RENARD, ALPHONSE FRANÇOIS (1842–1903), Belgian geologist, was born at Renaix on Sept. 27, 1842.

His first work (with Charles de la Vallée-Poussin, 1827–1904), was the *Mémoire sur les caractères mineralogiques et stratigraphiques des roches dites plutoniennes de la Belgique et de l'Ardenne française* (1876). In later essays and papers he dealt with the structure and mineral composition of many igneous and sedimentary rocks, and with the phenomena of metamorphism in Belgium and other countries. Still more important were his later researches connected with the Challenger Expedition. The various rock specimens and oceanic deposits were submitted to him for examination in association with Sir John Murray, and their detailed observations were embodied in the *Report on the Scientific Results of the Voyage of H.M.S. "Challenger." Deep Sea Deposits* (1891). The more striking additions to our knowledge included "the detection and description of cosmic dust, which as fine rain slowly accumulates on the ocean floor; the development of zeolitic crystals on the sea-bottom at temperatures of 32° and under; and the distribution and mode of occurrence of manganiferous concretions and of phosphatic and glauconite deposits on the bed of the ocean" (Geikie). Renard was professor at the Jesuit College of Louvain and then at the University of Ghent. He died at Brussels on July 9, 1903.

Obituaries by Sir A. Geikie in *Quart. Journ. Geol. Soc.*, lx. 1904, and in *Geol. Mag.*, Nov. 1903.

RENAUD DE MONTAUBAN (Rinaldo di Montalbano), one of the most famous figures of French and Italian romance. His story was attached to the *geste* of Doon of Mayence by the 13th-century *trouvère* who wrote the *chanson de geste* of *Renaus de Montauban*, better known perhaps as *Les quatre fils Aymon*. The four sons of Aymon give their name to inns and streets in nearly every town of France, and Renaud's sword Floberge, and his horse Bayard passed with him into popular legend. The poem opens with the dissensions between Charlemagne and the sons of Doon of Mayence, Beuves d'Aigremont, Doon de Nanteuil and Aymon de Dordone. The rebellious vassals are defeated by the imperial army near Troyes, and, peace established, Aymon rises in favour at court, and supports the emperor, even in his persecution of his four sons, Renaud, Alard, Guichard and Richard. At the end of the usual series of violent adventures and catastrophes, Renaud gives himself up to religion, working as a mason on the church of St. Peter at Cologne, where he receives martyrdom at the hands of his jealous fellow-labourers.

The connection of the four brothers with Montessor, Dortmund, Mayence and Cologne, and the abundant local tradition, mark the heroes as originating from the region between the Rhine and the Meuse. Nevertheless, their adventures in Gascony, with the king of which they take service against the Saracens, are

corroborated by historical evidence, and this section of the poem is the oldest. The enemy of Renaud was Charles Martel, not Charlemagne; King Yon was Odo of Gascony; the victory over the Saracens at Toulouse, in which the brothers are alleged to have taken part, was won by him in 721, and in 719 he sheltered refugees from the dominions of Charles Martel, Chilperic II., king of Neustria, and his mayor of the palace, Raginfred, whom he was compelled to abandon. In a local chronicle of Cologne it is stated that St. Reinoldus died in 697, and in the Latin rhythmical *Vita* his martyrdom is said to have taken place under Bishop Agilolf (d. 717). Thus the romance was evidently composite before it took its place in the Carolingian cycle.

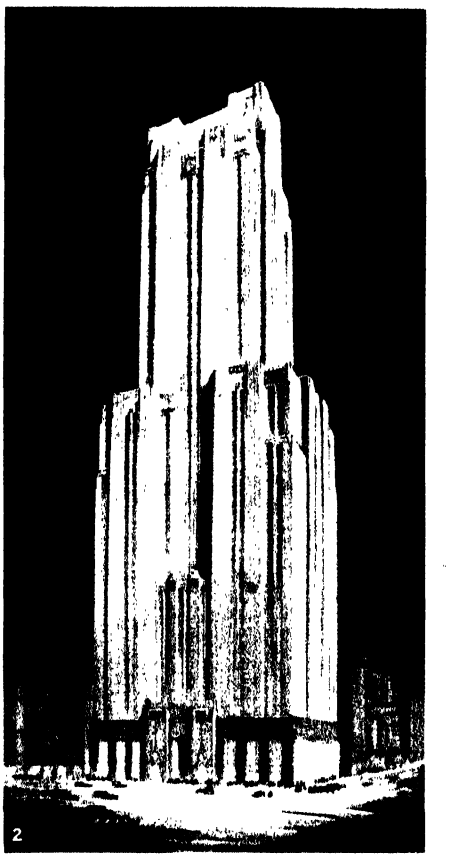
In Italy Renaud had his greatest vogue, and many episodes were added, as well as the personage of the hero's sister, Bradamante. Rinaldo di Montalbano had been the subject of many Italian poems before *Il Rinaldo* of Tasso.

BIBLIOGRAPHY.—The *chanson* of *Maugis d'Aigremont* and the prose romance of the *Conqueste de Trebizonde* belong to the same cycle. The prose *Vstoire de Regnault de Montauban* (Lyons, *c.* 1480) had a great vogue. It was generally printed as *Les quatre fils Aymon*, and was published in English, *The Foure Sonnes of Aymon*, by William Caxton, and subsequently by Wynkyn de Worde and William Copland. See *Hist. litt. de la France*, xxii., analysis by Paulin Paris; *Renaus de Montauban* (Stuttgart, 1862), ed. H. Michelant; *Storia di Rinaldino*, ed. C. Minutoli (Bologna, 1865); F. Wulff, *Recherches sur les sagas de Magus et de Geirard* (Lund, 1873); *Renout von Montalbaen*, ed. J. C. Matthis (Groningen, 1873); *Magus saga*, ed. G. Cederschiöld (Lund, 1876); A. Longnon, in *Revue des questions historiques* (1879); R. Zwick, *Über die Sprache des Renaut von Montauban* (Halle, 1884); *The Four Sonnes of Aimon* (E. E. Text Soc., ed. Octavia Richardson, 1884); F. Pfaff, *Das deutsche Volksbuch von den Heymonskindern* (Freiburg in Breisgau, 1887), with a general introduction to the study of the saga; a special bibliography of the printed editions of the prose romance in L. Gautier's *Bibl. des chansons de geste* (1897); rejuvenations of the story by Karl Simrock (Frankfort, 1845), and by Richard Steele (1897).

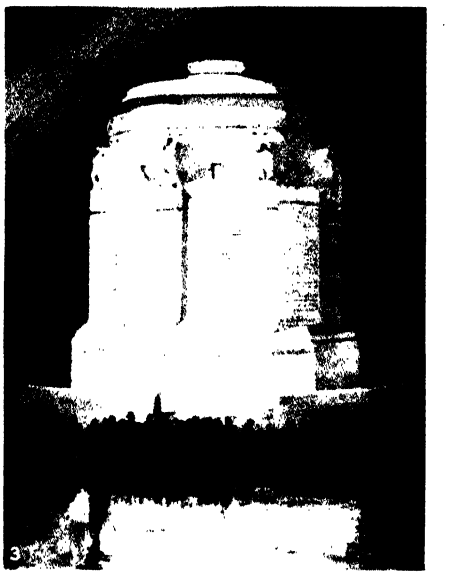
RENAUDOT, THÉOPHRASTE (1586–1653), French physician and philanthropist, was born at Loudun (Vienne), and studied surgery in Paris. He was only nineteen when he received, by favour apparently, the degree of doctor at Montpellier. After some time spent in travel he began to practise in his native town. In 1612 he was summoned to Paris by Richelieu, received the titles of physician and councillor to the king, and was desired to organize a scheme of public assistance. Many difficulties were put in his way, however, and he returned until 1624 to Poitou, where Richelieu made him "commissary general of the poor." But in 1630 he opened an information bureau in Paris at the sign of the Grand Coq near the Pont Saint-Michel. This *bureau d'adresse* was labour bureau, intelligence department, exchange and charity organization in one; and the sick were directed to doctors prepared to give them free treatment. Presently he established a free dispensary in the teeth of the opposition of the faculty in Paris. The Paris faculty refused to accept the new medicaments proposed by the heretic from Montpellier, restricting themselves to the old prescriptions of blood-letting and purgation. Under the protection of Richelieu Renaudot started the first French newspaper, the *Gazette* (1631), which appeared weekly; he also edited the *Mercure français*. In 1637 he opened in Paris the first Mont de Piété, an institution of which he had seen the advantages in Italy. In 1640 the medical faculty, headed by Guy Patin, started a campaign against the innovator of the Grand Coq. After the death of Richelieu and of Louis XIII. the parlement of Paris ordered him to return the letters patent for the establishment of his bureau and his Mont de Piété, and refused to allow him to practise medicine in Paris. The *Gazette* remained, and in 1646 Renaudot was appointed by Mazarin historiographer to the king. He died on Oct. 25, 1653.

See E. Hatin, *Théophraste Renaudot* (Poitiers, 1883), and *La Maison du Coq* (Paris, 1885); Michel Emery, *Renaudot et l'introduction de la médication chimique* (Paris, 1889); and G. Bonnefont, *Un Oublié, Théophraste Renaudot* (Limoges, n.d.).

RENDERING, ARCHITECTURAL. Architectural rendering is a pictorial art whose object is to visualize architectural conceptions. When an architect is employed to design a building, it is desirable that he provide his client, in advance, with an accurate impression of the appearance of the proposed structure. Since words cannot adequately convey the architectural story, paintings or drawings are employed to render it, as it were, clear to the eye; they serve as a kind of communication. This is the most familiar application of the art; and, when so used, rendering may be defined as the medium whereby the renderer communicates a sense of the reality of a structure in advance of its concrete materialization. Occasionally, however, the architect has a rendering made in the course of his own work and as an aid to his own study. When an architectural conception first forms in the background of his mind, it has, of necessity, a certain nebulous character. But with the effort of expressing it on paper, in actual lines and tone values, it emerges, so to speak, and crystallizes. When so employed, rendering serves as a definite step in the evolution of architectural conceptions.



Rendering has a third use; viz., in connection with already existing buildings. When so used, renderings—as distinguished from the miscellaneous paintings and drawings that refer only incidentally to architecture—have, as their chief or sole concern, to render clear the strictly architectural nature of the subject. By this selection of architectural factors, they may enable the layman to grasp the significance of a building more readily than when faced by its multitudinous and irrelevant details. At the same time, they may serve as a faithful record of the historic course of architectural design. In these three ways, rendering fulfills a recognized function, and has done so over a long period.



In the last quarter of a century, there has developed an aspect of architectural and engineering practice that involves rendering on a more extended scale—town and city planning (*q.v.*). A comprehensive plan for the future building development of any large community is never the conception of a single mind; many minds must collaborate in it. Nor is it materialized in a few years, but in many years. In these circumstances, it becomes impractical for its whole purport to be carried only in any single given mind, or for an accurate image to be postponed until the whole long scheme has been consummated. The various contributory ideas and suggestions must be assembled, in definitive terms, on the paper or canvas of the rendering, in order that the prophecy may assume sufficient reality to serve as a criterion and a guide.

Another factor, which more clearly reveals the contemporary field of rendering, is that Western architecture, as a whole, is passing through a period of transition and, therefore, of experiment (*see* ARCHITECTURE). It is true that the practice of many of the most prominent architects is to continue constructing mere copies, or very slightly modified copies, of those classic styles which, in their impressionable years, they were led to regard as being the very body of architectural culture; their effort is to emulate the classic designers in all respects, save, perhaps, the latter's logic, sense of congruity and ability to fashion novel forms. Their public, accordingly, has been wont to feel the presence of architecture only in a building to which the architect has added a Greek colonnade, a Roman dome or a Gothic spire. In all this, professional rendering has been able to play but a small part, since the picture has been regarded as an end in itself simply to be made as attractive as possible; it could scarcely be employed as a means of rendering forth a new truth, more especially as the appearance of these styles of architecture has been known for centuries.

In recent years, however, definite changes have occurred in methods of construction and the manufacture of materials, as well as in the general social and economic situation; and one notices that in the larger centres of Western civilization a distinct type of designer is making his presence in the architectural profession more and more strongly felt. These designers are inspired not so much by the traits of an architectural heredity as by the needs of contemporary environment. For them, the tremendous environmental changes that have occurred imply and demand a corresponding change in the architectural approach. They do not—to choose one example—employ a new material, steel, to support façades, which have developed in other materials and can be logical only therein. They are engaged, briefly, in developing new types of architecture. Certain limitations lie upon these practising

BY COURTESY OF (2) HOLABIRD AND ROCHE, ARCHITECTS

EXAMPLES OF VARIOUS TYPES OF RENDERINGS

1. Carbon pencil drawing on cameo paper: made to visualize a proposed structure; effect of mass remaining dominant in spite of thoughtful delineation of detail; sense of relation to surroundings. By Chester B. Price. 2. Crayon drawing: made to visualize proposed structure; arbitrary handling of tone values, details and entourage resulting in an unusual impression of mass. By Gilbert P. Hall. 3. Wash: made to visualize a proposed structure; grasp of architectural factors, sensitive feeling, conveyed through a cultured technique. By H. VanBuren Magonigle

RENDERING, ARCHITECTURAL

BY COURTESY OF (1) B. G. GOODHUE

EXAMPLES OF RENDERINGS, VARIOUS AS TO MEDIUM, USE, CONTENT AND STYLE

1. Water colour: made to convey general impression of a proposed structure in relation to its natural surroundings; adequate consideration of material reality of the general scene; architectural elements handled impressionistically with detail omitted; pictorial values predominating; emphasis on atmosphere and colour. By Birch Burdette Long
2. Lithograph: made to vivify an historical subject; cautious delineation of material facts; intelligent exaggeration of scale, conveying emotion of dignity, mystery, spaciousness. By David Roberts (1796–1864)
3. Pencil drawing, with wash: made to visualize proposed structures; fine discrimination between essentials and details, resulting in a convincing sense of reality both as to structural and human factors. By Thomas R. Johnson
4. Water colour over pencil layout: made to visualize proposed interior; fidelity to material detail. By Houghson Hawley
5. Pencil drawing on tracing paper with water colour used after mounting: made to visualize proposed addition to existing structure; complete comprehension of architectural factors conveyed by a perfected technique. By Otto Eggers

and experimental architects. It is sometimes too hazardous to test a novel conception by actually carrying it out in a building which, whether a success or a failure, must stand for many years. But the conception may be quite thoroughly tested in a series of conscientious renderings. For example, the modern American zoning laws involved a radical departure in the general forms of buildings, and into the strange spaces created by these laws some architects proceeded without pause to force the classical images with which their minds were filled. More cautious architects sought to discover the basic structural types that the laws admitted; for this purpose, renderings were employed. Another limitation is that the projects of architects are practically bound by the ideas and the financial resources of their clients; they cannot actually build in advance of their clients' prepossessions. In renderings, however, they may freely express their real intentions, and these renderings, when duly exhibited can, and in fact do, make a distinct contribution to the progress of architectural design. A third limitation is that no practising architect, however fortunate, has time to build more than a very few influential buildings during his lifetime. He may, however, record himself in soundly fashioned drawings and paintings whose content, though at first existing in only two dimensions, may, in due time, be realized in three.

In addition to the functions thus far mentioned, rendering has a rôle to play in what is doubtless the greatest concern of architecture—the psychological influence it exerts on human life. A few people, it is true, are fully conscious of the impressions that they receive in the face of noble buildings; the more pertinent and important fact is that the vast majority of human beings are continually, if unconsciously, influenced by the architectural forms and spaces with which they come in contact. Architects themselves are often unaware of the extent of this influence; that is to say, the influence which is unconsciously received is unconsciously initiated. Perhaps it is in consequence of this that the haphazard and miscellaneous architectural scene which is presented by most modern cities, and which is constantly before the population, is left to impress the corresponding qualities upon the human psyche. On the other hand, there have been periods in the past—the "great periods" of architecture—when the designers must have been quite aware of the influence, and utilized it for conscious purposes. In the Gothic cathedrals, for example, there is embodied, in terms of form and space (terms safely beyond the vicissitudes of any particular church) a potent and lasting influence for the betterment of mankind. Buildings of the first category—depressing or distracting buildings—are legion; those of the second—buildings which arrest or elevate—are rare. But the more significant forms may be repeatedly delineated and interpreted in drawings and paintings by whose agency they may be widely exhibited, published and, so to speak, broadcast. Rendering, in short, by allying itself with the conscious and objective forces in architectural work, may serve, by paraphrase, to bring home the laconic message of architecture.

To sum up, rendering has six principal objects. The first three have long been recognized: to convey advance realizations of proposed structures, to aid in crystallizing ideas in the architect's mind and to interpret the architectural significance of existing structures. The other three remain largely for future development: to serve as criterion and guide in city planning, to assist in evolving new types of architecture and to strengthen the psychological influence of architecture on human values.

Whichever of these objects a given rendering is to serve, the renderer—having comprehended *why* the drawing is being made—is faced with two fundamental considerations. The first is to grasp *what* is the nature of the architectural subject to be rendered, to so ponder it as to exclude non-essentials. The second is *how* to employ the various devices of draughtsmanship so as to communicate this realization to others. Between these two items—the nature of the subject and the process of rendering—there exists the distinction between ends and means, and it is important that the renderer have this distinction clearly in mind at the outset.

As a matter of common practice, this distinction is often not made. The painting or drawing is often regarded as being an end in itself, and discussion of it centres, in consequence, on purely technical questions: interest of composition, nicety of line, cleverness of brushwork, etc. Many such works are contributions to the subject of technique and justify the enthusiasm of technicians; but, lacking architectural significance, they are not, strictly speaking, architectural renderings.

It is also a common practice to regard rendering as indeed a means but to substitute for its authentic and natural ends, ends that are special or perverted. For example,—as in the Beaux Arts curriculum—projects are often rendered in elevation (*i.e.*, the representation is of but one façade of the building as this would appear were the eye directly opposite each and every point thereon). This, obviously, produces a form which can exist only on paper; it is not the form which the human eye would perceive in the building itself. Such a treatment serves a purpose, in that an architect, when reading its conventionalized and inexact statement, can translate it, in his trained mind, into at least an approximation of the truth. But just because it requires a translation, and is, in itself, foreign to reality, it may be classified as a special practice.

Another common practice, of a different category, is to accomplish, by means of a picture, an end which is positively opposed to architectural fact. The renderer may be called on to exaggerate certain aspects of a proposed building in order to create a more favourable advance impression; or to exaggerate certain factors of an existing building in a way to advertise them. The architect or advertiser may wish such a rendering as a result of deliberate calculation or because his personal interest in particulars is so great as to obscure from his view the real appearance of the building in its entirety. In any case, the executing of such commissions falls rather into the class of commercialized art and may be excluded from a discussion on rendering.

The twofold criterion of values remains to be applied to all renderings: first, comprehension of the architectural essentials involved in the subject; second, effectiveness in pictorial communication.

ESSENTIALS TO BE RENDERED

Mass.—From the renderer's point of view a building is, in the first place, a material mass. While it is not, in actuality, a mass in the sense that a mountain is a mass, *i.e.*, it is not a solid, nevertheless the effect of solidity is essential to it. And while, in constructing a building, this effect may be the last to be realized, in drawing a building it is logically the first. The renderer must realize the presence of mass before he can fully realize the presence of any appurtenant form. It may be likened to the clay which a sculptor must grasp before any particular shape can be given or any details modelled. The first necessary attribute of a convincing architectural rendering is, correspondingly, an adequate suggestion of mass. Without this primary effect of solidity, all details which may be delineated later must appear without body and the presentation as a whole must lack substance.

Form.—Being imbued with a sense of the substantial nature that his subject, in general, possesses, the renderer addresses himself to a study of its particular form. It is generally taken for granted that if accurate floor plans and elevations are available, an accurate image of the building can be produced by following the rules of perspective draughtsmanship—those rules are said to have originated with Leonardo and are commonly accepted as being correct and comprehensive. The fact is, however, that there is considerable question as to how forms really look. It is quite doubtful if the system of perspective draughtsmanship which we accept as a science, is more than a convention—a convention which, indeed, is usually of great help to accurate representation and yet, in numerous instances, is a specific hindrance. The forming, in the human eye of images of buildings appears, in fact, to involve factors with which we, as renderers, have not yet adequately dealt (*see* PERSPECTIVE).

The Single Viewpoint.—One item to be considered in this connection is that, in laying out perspectives the draughtsman habitually assumes that the subject is being viewed from a single viewpoint. He establishes, on his draughting board, a specific

point, termed the "viewpoint" and his operations proceed from this base. But this assumption is inadequate to the extent that the appearance which a building actually produces on a one-eyed man is inadequate as compared to that produced on a two-eyed man. In some cases, the discrepancy is not remarkable—as, for example, small forms viewed at considerable distances. But, in forms which are closely scrutinized, the discrepancy becomes pronounced; there is a definite lack of the three-dimensional quality to the single-eyed vision, and there is a corresponding flatness to the general run of perspectives laid out from the single viewpoint.

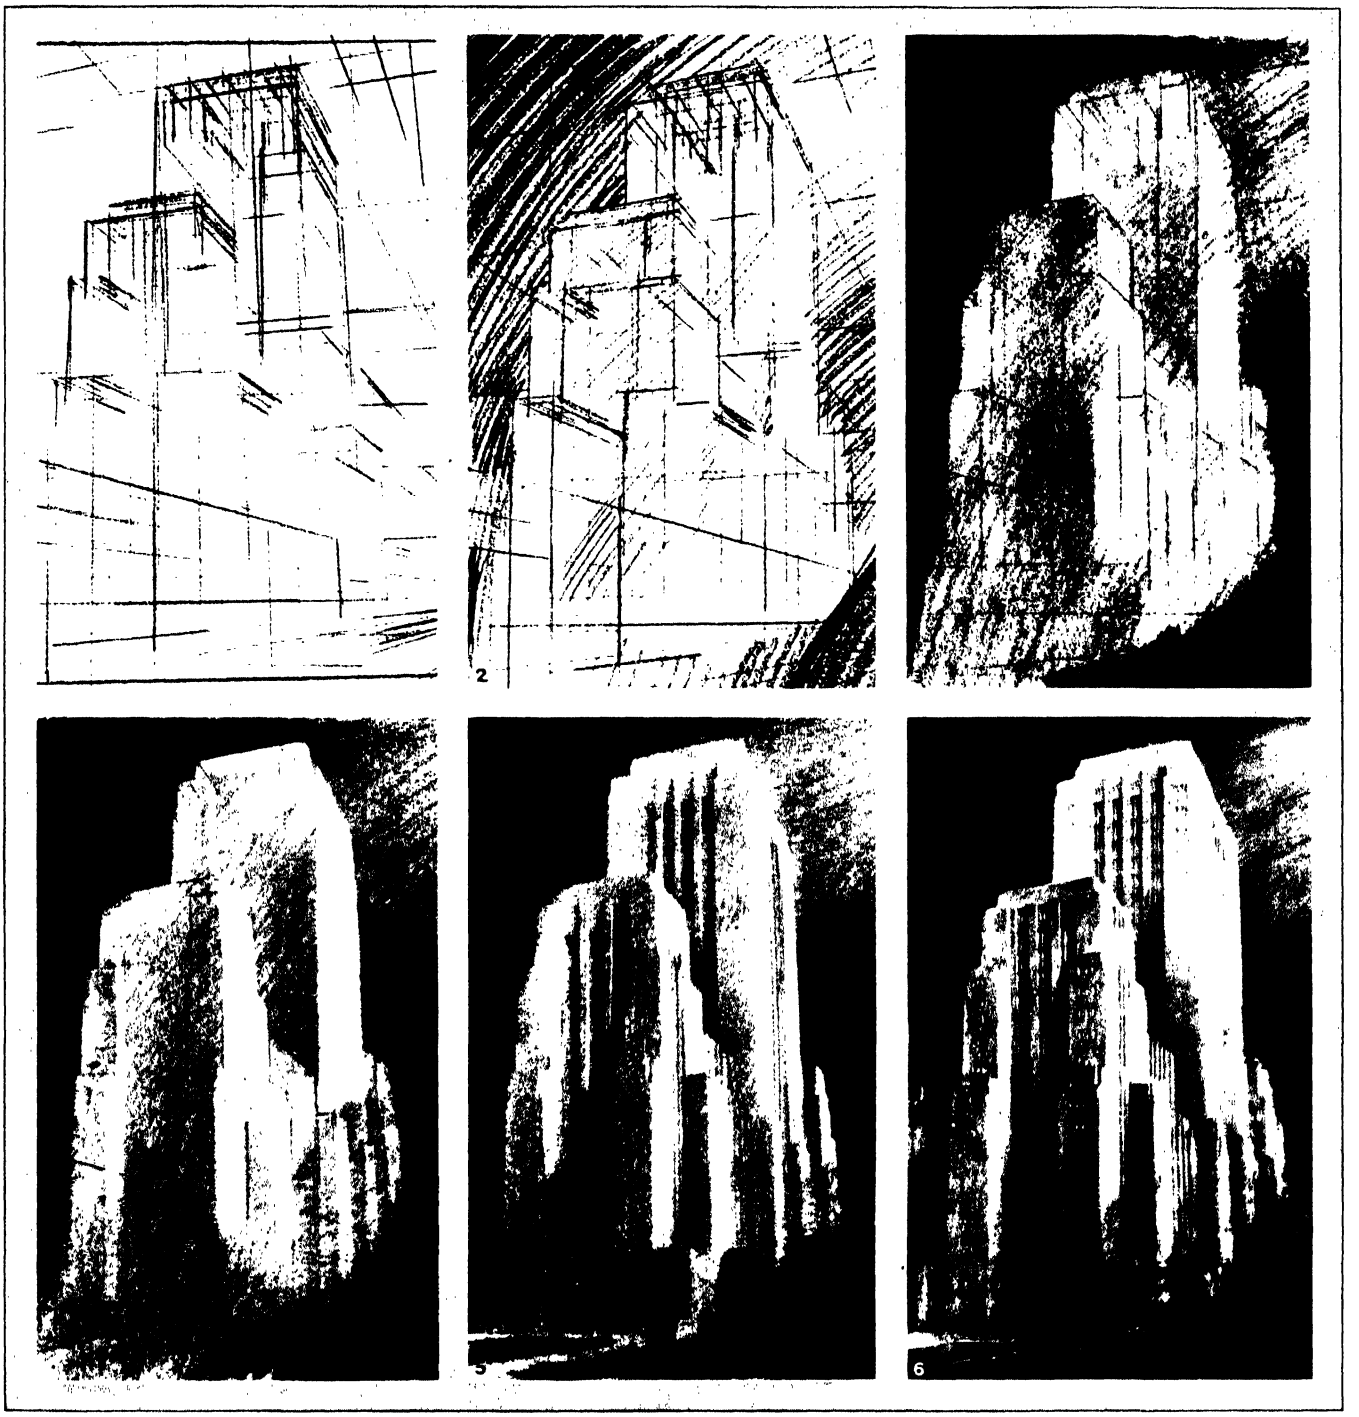
The Stationary Viewpoint.—A second item is that a draughtsman in laying out his perspective assumes, according to the convention, that his single viewpoint is stationary. In reality, however, an observer in forming his image of a building, assumes a series of viewpoints. In seriously studying a building, one will purposefully view it from many different angles; but even if the interest is only casual one will instinctively look at it more than once—always from a viewpoint which is, of necessity, slightly altered. In all cases, it may be said that the image which the observer takes away with him is not the single first impression received from a literally stationary viewpoint, but is a composite of several distinct impressions. This composite quality of the image is an essential which demands the renderer's attention: how he may, by a cunning draughtsmanship, convey this aspect of the case is considered in this article under the heading of "Procedure."

The foregoing consideration involves a problem that often appears in rendering; viz., one is often faced with the necessity of choosing between a truthful pictorial statement of the building which is being drawn and a truthful statement of the viewpoint which happens to have been chosen.

It is usually held that when a viewpoint has once been selected, it is demanded by honesty that all items of the scene (including adjoining buildings) must be delineated exactly as they appear; that if one arbitrarily makes alterations (as, for example, showing adjoining buildings less prominently than they actually are) he is guilty of "faking." Undeniably, many renderings are "faked"; at the same time, there is a distinction to be made. If the alteration has been made for the purpose of conveying a more favourable impression than the actual scene, then the charge of misrepresentation is, obviously, sustained. It often happens, however, that a building possesses a very important feature which, while entirely visible from many points of view, may happen to be screened from the particular point of view that has been chosen. For instance, a building may possess a certain buttressing member which gives its tower integrity, and which may be visible from many viewpoints, but this member may be hidden from the chosen viewpoint by some extraneous and perhaps temporary obstruction. We may assume at the same time, that the renderer's commission is to depict the building as truthfully and completely as possible in a single drawing. In such a case, it would appear that he is not so much permitted as actually required to slight incidental facts of his viewpoint in favour of the essential facts of the subject which he is viewing.

Perspective of Vertical Lines.—Another item demanding the renderer's attention is that all effects of perspective which a building presents to the human eye apply to its vertical as well as to its horizontal extension. Although this is obviously so, the current convention of perspective generally disregards it, the horizontal lines, only, being drawn to meet in a "vanishing point," but the vertical lines being arbitrarily drawn parallel to each other. In the case of very low buildings, the discrepancy is not important; but in the cases, now so numerous, of very tall buildings, the inaccuracy is serious. The convention not only produces distorted drawings, but so habituates onlookers to distortion that they become disinclined to recognize normal appearances.

Method of Construction.—The renderer may, to a considerable degree, express in his drawing such differences of appearance as exist, for example, between a building of solid masonry and one of steel grille construction. His medium allows considerable variety of indication of texture characteristic of stone, brick, terra-cotta, glass, etc.



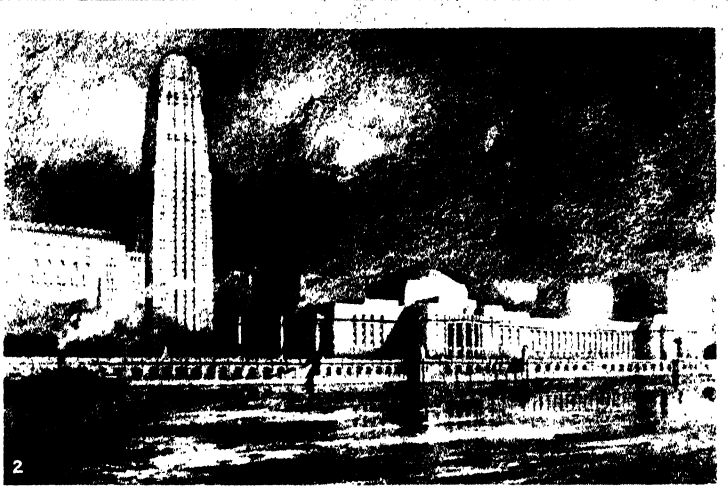
Atmospheric Conditions.—Buildings are, of necessity, seen through a physical atmosphere and a suggestion of reality obviously cannot be conveyed in a drawing in which an atmospheric condition is not convincingly suggested; some renderings, for instance, fail by conveying the suggestion that the subject was viewed through a vacuum.

The important question of colour belongs to a general study of the painter's art (*see* PAINTING; WATERCOLOUR PAINTING).

In addition to these material factors, an architectural subject presents others of a psychological nature. A realistic rendering may, indeed, be produced by dealing honestly with only the physical facts; an authentic rendering, however, demands a realistic treatment of intellectual and emotional aspects as well. In this connection, the following experiment is illustrative. An exact perspective was laid out of the form of the Woolworth building, using the architect's blue prints as a basis. A second study was made, sketching from the building itself from an exactly corresponding viewpoint. The building was then photographed from this viewpoint. On comparing the three results it was found that the principal proportions were different in each case. The more striking conclusion was that none of them conveyed the sense of structural logic which the disposition of the steel members themselves conveys to the thoughtful observer; none of them suggested the emotion of soaring aspiration which the form itself suggests to the human onlooker. It becomes, indeed, one of the chief concerns of the renderer to comprehend the nature of the architectural idea which his subject embodies, the trend of thought the architect has expressed. Similarly, the renderer must especially aim to appreciate the emotional tone, the particular mood, of his subject. On entering these outlying psychological domains rendering, like the other arts, may attain its happiest freedom of movement. Yet just here, unfortunately, it must evade competent technical guidance. We have many paintings and drawings which succeed in conveying an isolated thought or an isolated emotion; but too often we find that the renderings which have attained this success have paid in distorted material proportions.

Viewed in this way, renderings as a whole fall into certain rather well-defined groups. The largest, and most familiar, includes those in which the renderer has made a competent presentation of the material facts, but has failed to include any of those elements which, in architecture, stimulate the mind and arouse the emotions. It is as though he worked only with his hands, neither his thought nor feeling having been involved. The result is correct but chilling. A second group is that in which only an emotional aspect of the subject has been fully rendered, just as a third is that in which only an intellectual aspect has been emphasized. Such works, generally labelled "impressionistic," "futuristic," etc., often convey what was intended yet fail of permanent value in that they distort or omit the physical facts of the case. If, for example, the subject be a mausoleum which has, in actuality, an atmosphere of solemnity, such a rendering may—perhaps in a few dark washes—convey an emotion of solemnity but leave the mausoleum itself in doubt. Or, if the subject be a tower notable for its logical growth, the rendering may—perhaps in a few cold lines—suggest logical growth but refer to no particular tower. There follow, naturally, three further groups in which the result is more appealing or convincing: that in which the material facts have been accurately presented in a thoughtful manner; that in which they have been presented with appreciable emotion; and that in which, while the material facts have been presented inexactly, a clear architectural thought appears accompanied by deep feeling. The ideal, which would constitute a seventh group, would be to convey the material, the emotional and the intellectual facts in the same rendering.

Why renderings should fall into these various groups is probably not difficult to ascertain: they do so by following the various personalities of the renderers. A draughtsman naturally draws that aspect of a building which he is by habit inclined to appreciate. From one renderer, we shall almost always get a very correct and cold drawing; from another a very bold and incorrect drawing. This suggests the reason why a perfectly balanced rendering has never been produced. It also suggests a point of interest to the



PROGRESSIVE VIEWS OF A RENDERING

A rendering by Hugh Ferriss, showing: 1. Lines drawn, tentatively suggesting a mass in space. 2. Additional lines added as material for tone values. 3. Lines rubbed together with paper stump, producing tone values to confirm indication of mass. 4. The form further modelled by use of kneaded eraser on right hand planes. 5. Principal subdivisions of the mass delineated, also by use of (1) pencil, (2) paper stump and (3) kneaded eraser. 6. Minor items introduced, same process. (*See* section of article on *Procedure*.)

RENDERING, ARCHITECTURAL

Jany - 1896

RENDERINGS IN VARIOUS MEDIUMS

1. Engraving: structural factors, accurately sensed, recomposed with a virile imagination, conveying powerful emotional impression. By Piranesi (1720–76). 2. Pencil drawing, coffee wash: made to visualize a civic project; primarily concerned with the architectural conception, yet adequate attention given to pictorial values. By Eliel Saarinen. 3. Etching: imaginary composition on historical motif; highly stimulating impressions. By William Walcot. 4. Pastel: selection of architectural factors from an existing building; thoughtful composition of subject matter, affectionate attention to technique. By T. de Postels. 5. Pencil: example of a one minute sketch made to convey an architect's conception to his assistants; attention centred on essentials of the design (which were later constructed as sketched). By Cass Gilbert

student of rendering, it may well be that he will develop his art not simply by cultivating whatever tendency he happened to exhibit in the beginning, but, rather, by seeking to add to his forces some tendency which was not habitual to him. For example, if he is in the way of being an excellent draughtsman, he might seek to acquire an emotional appreciation of architecture in addition; just as, if he has always had strong feelings about buildings, he might seek to comprehend the pure logic by which all architectural masterpieces are given form. When thus regarded, rendering becomes, for the renderer himself, not so much a matter of self-expression as of self-development.

PROCEDURE

To answer the remaining question—*how* to make a rendering—it is necessary, since there are numerous equally promising methods of procedure, to describe the method employed in a specific case. In the case of the rendering reproduced in fig. 1–6 of Plate III. the procedure was as follows:—

A sheet of mounted Whatman paper 27 by 40 in. was tacked to a slightly larger drawing board and placed on a vertical easel. The draughtsman standing before the easel, made the assumption that, for the moment, the paper represented *space*. With the intention of introducing into this space, the presence of *mass*, a number of lines were lightly sketched in, using a 3B Wolff crayon (*see* fig. 1). These lines fall into three groups, according to their direction; they proceed, respectively, from three previously assumed "vanishing points" (*see* PERSPECTIVE). They serve the draughtsman as an adequate notation of the three-dimensionality which characterizes any mass in space. While sketching these generalized lines, he emphasized such as would tentatively indicate the particular form that he intended to give the mass—the form which, until now, had existed only in his mind. The next step was to confirm and solidify these outlines by introducing tone values—produced by drawing, rapidly, a number of freehand lines across the areas to be shaded (*see* fig. 2) and rubbing these lines together into a tone with a gloved finger or a paper "stump" (*see* fig. 3). In the rendering now under consideration, the degree of solidity which was desired at this stage was effected by producing three general tones—the background being the darkest, the planes of the building which face toward the left being intermediary, and the planes which face toward the right being the lightest. The last tone was produced by cleaning the areas with a "kneaded" eraser (*see* fig. 4).

At this point, the draughtsman had before him a visualization, vivid enough for his own purposes, of the basic form of the building. His next step was to identify, in his mind, the principal subdivisions of his preconceived design and to indicate, on the paper, these modifications of the basic form. This involved a repetition, at a smaller scale, of his previous procedure; that is to say, he first sketched in the minor forms in line and then solidified them with tone values, using glove, stump and eraser. At this point another tone value was added to contribute further to the effect of solidity; *i.e.*, the cast shadows (*see* fig. 5). The same process of indicating form in line was repeated again and again—each time dealing with a category of smaller forms—until the building appeared in that degree of detail which seemed best calculated to serve the purposes for which the drawing was undertaken (*see* fig. 6).

Of renderings of this sort, it might be said that the draughtsman begins his task in this spirit: he is, metaphorically, facing a building which, although it exists in its entirety, is completely hidden from him in a mist or fog. As he approaches his subject, however, he begins to discern the principal outlines of its mass. Soon its secondary and tertiary features appear. He is free to continue his approach until the most minute details have become plain. Nevertheless, it is important that he halt at that point where his subject has revealed all that is essential to his inquiry.

The numerous other methods of rendering, all equally useful, can best be studied in reproductions of actual renderings; such material, with explanatory notes, is shown in the accompanying plates. They all point to the same conclusion—the draughtsman's best procedure is first to delineate the essentials of his subject, then to build all indication of detail on this foundation.

RENDSBURG, a town in the Prussian province of Schleswig-Holstein, situated on the Eider and on the Kaiser Wilhelm canal, 20 m. W. of Kiel, on the Altona-Flensburg railway. Pop. (1925) 17,036. Rendsburg came into existence under the shelter of a castle founded by the Danes about the year 1100 and was an object of dispute between the Danish kings and the counts of Holstein. In 1252 it was adjudged to the latter and the town was surrounded with ramparts in 1539. The war of 1848–50 began with the capture of Rendsburg by the Holsteiners and it formed the centre of the German operations. In Nov. 1863 the town was occupied by the Saxon troops acting as the executive of the German Confederation, and it was the base of the operations of the Austrians and Prussians against Schleswig in the spring of the following year. Rendsburg was jointly occupied by Austrian and Prussian military until 1866, when it fell to Prussia. It consists of three parts—the crowded Altstadt, on an island in the Eider; and new towns on the north and south banks of the river. Its importance rests on the commercial facilities afforded by its connection with the North sea and the Baltic through the Kaiser Wilhelm canal, by which transit trade is carried on in grain, timber, Swedish iron and coals. The principal products are dyes, iron, artificial manures, machines and tobacco.

RENÉ I. (1409–1480), duke of Anjou, of Lorraine and Bar, count of Provence and of Piedmont, king of Naples, Sicily and Jerusalem, was born at Angers on Jan. 16, 1409, the second son of Louis II., king of Sicily, duke of Anjou, count of Provence, and of Yolande of Aragon. By his marriage treaty (1419) with Isabel, elder daughter of Charles II., duke of Lorraine, the comte de Guise, as he then was, became heir to the duchy of Bar, which was claimed as the inheritance of his mother Yolande, and, in right of his wife, heir to the duchy of Lorraine. René, then only ten, was to be brought up in Lorraine under the guardianship of Charles II. and Louis, cardinal of Bar, both of whom were attached to the Burgundian party, but he retained the right to bear the arms of Anjou. When Louis of Bar died in 1430 René came into sole possession of his duchy, and in the next year, on his father-in-law's death, he succeeded to the duchy of Lorraine. But the inheritance was claimed by the heir-male, Antoine de Vaudémont, who with Burgundian help defeated René at Bulgnéville in July 1431. The Duchess Isabel effected a truce with Antoine de Vaudémont, but the duke remained a prisoner of the Burgundians until April 1432, when he recovered his liberty on parole, on yielding up as hostages his two sons, Jean and Louis of Anjou. His title as duke of Lorraine was confirmed by his suzerain, the Emperor Sigismund, at Basel in 1434. This proceeding roused the anger of the Burgundian duke, Philip the Good, who required him early in the next year to return to his prison, from which he was released two years later on payment of a heavy ransom. He had succeeded to the kingdom of Naples through the deaths of his brother Louis III. and of Jeanne II. de Duras, queen of Naples, the last heir of the earlier dynasty. Louis had been adopted by her in 1431, and she now left her inheritance to René. The marriage of Marie de Bourbon, niece of Philip of Burgundy, with John, duke of Calabria, René's eldest son, cemented peace between the two princes. After appointing a regency in Bar and Lorraine, he visited his provinces of Anjou and Provence, and in 1438 set sail for Naples, which had been held for him by the Duchess Isabel. In 1441 Alphonso of Aragon laid siege to Naples, which he sacked after a six months' siege. René returned to France in the same year, and though he retained the title of king of Naples his effective rule was never recovered. René took part in the negotiations with the English at Tours in 1444, and peace was consolidated by the marriage of his younger daughter, Margaret, with Henry VI. at Nancy. René

now made over the government of Lorraine to John, duke of Calabria, who was, however, only formally installed as duke of Lorraine on the death of Queen Isabel in 1453. René had the confidence of Charles VII., and is said to have initiated the reduction of the men-at-arms set on foot by the king, with whose military operations against the English he was closely associated. He entered Rouen with him in November 1449, and was also with him at Formigny and Caen. After his second marriage with Jeanne de Laval, daughter of Guy XIV., count of Laval, and Isabel of Brittany, René took a less active part in public affairs, and devoted himself more to artistic and literary pursuits. The fortunes of his house declined in his old age. *See* ANJOU.

The king of Sicily's fame as an amateur of painting has led to the attribution to him of many old paintings in Anjou and Provence, in many cases simply because they bear his arms. These works are generally in the Flemish style, and were probably executed under his patronage and direction, so that he may be said to have formed a school of the fine arts in sculpture, painting, gold work and tapestry. Two of the most famous works formerly attributed to René are the triptych, the "Burning Bush," in the cathedral of Aix, showing portraits of René and his second wife, Jeanne de Laval, and an illuminated Book of Hours in the Bibliothèque nationale, Paris. The "Burning Bush" was in fact the work of Nicolas Froment, a painter of Avignon. Among the men of letters attached to his court was Antoine de la Sale, whom he made tutor to his son, the duke of Calabria. He encouraged the performance of mystery plays; on the performance of a mystery of the Passion at Saumur in 1462 he remitted four years of taxes to the town, and the representations of the Passion at Angers were carried out under his auspices. He exchanged verses with his kinsman, the poet Charles of Orleans. The best of his poems is the idyl of Regnault and Jeanneton, representing his own courtship of Jeanne de Laval. *Le Livre des tournois*, a book of ceremonial, and the allegorical romance, *Conqueste qu'un chevalier nommé le Cuer d'amour espris feist d'une dame appelée Doulce Mercy*, with other works ascribed to him, were perhaps dictated to his secretaries, or at least compiled under his direction. His *Oeuvres* were published by the comte de Quatrebarbes (4 vols., Paris and Angers, 1845–46). He died on July 10, 1480.

See A. Lecoy de la Marche, *Le Roi René* (2 vols., 1875); A. Vallet de Viriville, in the *Nouvelle Biographie générale*, where there is some account of the mss. of his works; and J. Renouvier, *Les Peintres et enlumineurs du roi René* (Montpellier, 1857).

RENÉE OF FRANCE (1510–1575), second daughter of Louis XII. and Anne of Brittany, was born at Blois on Oct. 25, 1510. After being betrothed successively to Gaston de Foix, Charles of Austria (the future emperor Charles V.), his brother Ferdinand, Henry VIII. of England, and the elector Joachim II. of Brandenburg, she married in 1528 Hercules of Este, son of the duke of Ferrara, who succeeded his father six years later. Renée's court became a rendezvous of men of letters and a refuge for the persecuted French Calvinists. She received Clément Marot and Calvin at Ferrara, and finally embraced the reformed religion. Her husband, however, who viewed these proceedings with disfavour, banished her friends, took her children from her, threw her into prison, and eventually made her abandon at any rate the outward forms of Calvinism. After his death in 1559, Renée returned to France and turned her duchy of Montargis into a centre of Protestant propaganda. During the wars of religion she was several times molested by the Catholic troops, and in 1562 her château was besieged by her son-in-law, the duke of Guise. She died at Montargis.

RENFREW, royal, municipal and police burgh and county town of Renfrewshire, Scotland, near the southern bank of the Clyde, 7 m. W. by N. of Glasgow, via Cardonald, by the L.M.S. railway. A small part of the burgh is in the parish of Govan, Lanarkshire. Pop. (1921) 14,161. Industries include large shipbuilding works, engineering, weaving, and the manufacture of hosiery, rubber and soap. The Clyde Trust has constructed a large dock here, and there is a ferry to Yoker. Robert III. gave a charter in 1396, but it was a burgh (Renifry) at least 250 years earlie Close to the town, on the site of Elderslie House, Somerled, lo of the Isles, was defeated and slain in 1164 by the forces Malcolm IV., against whom he had rebelled. In 1404 Robert I bestowed upon his son James (afterwards James I. of Scotlan the title of Baron of Renfrew, still borne by the Prince of Wale

RENFREWSHIRE, south-western county, Scotlan bounded north by the river and Firth of Clyde, east by Lanar shire, south and south-west by Ayrshire and west by the Firth Clyde. A small detached portion of the parish of Renfrew, sit ated on the northern bank of the Clyde, is surrounded on t landward side by Dumbartonshire. The county has an area 151,431 acres (excluding water). The surface is low and undula ing, except towards the Ayrshire border on the south-west, whe the principal height is Hill of Stake (1,711 ft.), and the confin of Lanarkshire on the south-east, where a few points attain height of 1,200 ft. The south-western hills are formed of volcan rocks, basalts, porphyrites, tuffs and agglomerates of the a of the Calciferous Sandstone series. Practically all the ar west of these rocks is occupied by the Carboniferous Limesto series. Boulder clays and glacial gravels and sands cover co siderable areas. Much of the higher land in the centre is we wooded. The Clyde forms part of the northern boundary of t shire. In the north-west Loch Thom and Gryfe Reservoir provi Greenock with water, and Balgray Reservoir and Glen Reservo reinforce the water-supply of a portion of the Glasgow are Castle Semple Loch and other lakes are situated in the south an south-east. The Glasgow, Paisley and Johnstone canal was co verted after 1882 into the track of the Glasgow & South-Weste (now L.M.S.) railway. Strathgryfe is the only considerable va in the shire. The scenery at its head is wild and bleak, but t lower reaches are pasture land. The wooded ravine of Glenkillo to the south of Paisley, is watered by Killock Burn, on which a three falls.

Agriculture and Industries.—The hilly tract contains muc peat-moss and moorland, but over those areas which are not th covered the soil, which is a light earth on a substratum of grav is deep enough to produce good pasture. In the undulating centr region the soil is better, particularly in the basins of the stream while on the flat lands adjoining the Clyde there is a rich all vium which, except when soured by excessive rain, yields hea crops. Of the total area over half is under cultivation, consi erably more than half of this being permanent pasture. Oats a grown extensively, and wheat is also cultivated. Potatoes, turni and mangolds are the leading green crops. Near the popul centres orchards and market gardens are found, and an increasi acreage is under wood. Horses are kept mostly for farming oper tions, and the bulk of the cattle are maintained in connection wi dairying. Sheep-farming, though on the increase, is not pros cuted so vigorously as in the other southern counties of Scotlan and pig-rearing is on the decline.

Coal, iron and fireclay are the principal minerals of Renfre shire. Granite, limestone and sandstone are quarried. T thread industry at Paisley is very extensive. Cotton and flax spi ning, printing, bleaching and dyeing are carried on at Paisle Renfrew, Barrhead and elsewhere; woollens and worsteds a produced at Greenock and Renfrew. Engineering works and ir foundries are found at Greenock, Port Glasgow, Paisley, Re frew, Barrhead and Johnstone. Sugar is a staple article of tra in Greenock and there are chemical works at Cathcart, Paisle Hurlet and Nitshill. Brewing and distilling are carried on Greenock and other places. Shipbuilding is especially importa at Greenock and Port Glasgow. Paper mills are established Greenock, Cathcart and Johnstone. Numerous miscellaneous i dustries—such as the making of starch, cornflour, earthenwa and soap are important in Paisley and elsewhere. Trade a fisheries are centred at Greenock.

The L.M.S. railway runs westwards from Glasgow by Paisl to Greenock, Gourock and Wemyss Bay; south-westwards Barrhead and other stations; and southwards to Busby. Oth lines run to Greenock by Paisley, Johnstone and Kilmalcol to Nitshill and other places south-westwards; by Lochwinno

(for Dalry and Ardrossan in Ayrshire); and to Renfrew jointly with the Caledonian.

Population and Administration.—In 1921 the population numbered 298,904; 14 persons spoke Gaelic only and 3,828 Gaelic and English. Thus though the shire is but twenty-seventh in point of size of the 33 Scottish counties, it is fourth in respect of population. The chief towns are Paisley (pop. 84,837), Greenock (81,123). Port Glasgow (21,023), Johnstone (12,474), Barrhead (11,466), Renfrew (14,136 in Renfrewshire), Gourock (10,128). The shire returns one member to parliament for the eastern, and another for the western division. Paisley and Greenock return each one member. Renfrewshire forms a sheriffdom with Bute, and there is a resident sheriff-substitute at Paisley and one at Greenock. The county is under school-board jurisdiction. For secondary and specialized education there are an academy high school at Greenock and a grammar school and technical school at Paisley.

History.—At the time of the Roman advance from the Solway the land was peopled by the British tribe of Damnonii. To hold the natives in check the conquerors built in 84 the fort of Vanduara on high ground now covered by houses and streets in Paisley; but after the Romans retired (410) the territory was overrun by Cumbrian Britons and formed part of the kingdom of Strathclyde, the capital of which was situated at Alclyde, the modern Dumbarton. In the 7th and 8th centuries the region practically passed under the supremacy of Northumbria, but in the reign of Malcolm Canmore became incorporated with the rest of Scotland. During the first half of the 12th century, Walter Fitzalan, high steward of Scotland, ancestor of the royal house of Stuart, settled in Renfrewshire on an estate granted to him by David I. Till their accession to the throne the Stuarts identified themselves with the district, which, however, was only disjoined from Lanarkshire in 1404. In that year Robert III. erected the barony of Renfrew and the Stuart estates into a separate county, which, along with the earldom of Carrick and the barony of King's Kyle (both in Ayrshire), was bestowed upon his son, afterwards James I. From their grant are derived the titles of earl of Carrick and baron of Renfrew, borne by the eldest son of the sovereign. Apart from such isolated incidents as the defeat of Somerled near Renfrew in 1164, the battle of Langside in 1568 and the capture of the 9th earl of Argyll at Inchinnan in 1685, the history of the shire is scarcely separable from that of Paisley or the neighbouring county of Lanark.

RENNENKAMPF, PAUL (1854–1918), Russian general, was born in 1854 and entered the army in 1873. In 1882 he was appointed to the General Staff. Promoted to the rank of general in 1900, he distinguished himself in the Russo-Japanese war (1904–05). In 1913 he was appointed to command of the troops in the Vilna Military District. In Aug. 1914 he commanded the I. Army which invaded Eastern Prussia. His inaction during the battle of Tannenberg, where the neighbouring army of Samsonov was destroyed on Aug. 26–29 was a bitter disappointment, and he was even suspected of treachery. Personally brave, Rennenkampf, as an army commander, showed himself in the strategic sphere alternately rash and timid, owing to his inability to grasp the situation as a whole. At the beginning of 1915 he was recalled, and later under the pressure of public indignation, dismissed from the service. In 1918 he was killed by the Bolsheviks.

RENNER, KARL (1870–), Austrian politician, was born on Dec. 14, 1870, the son of a peasant, at Dolní-Dunajovice, Moravia. He studied law at the university of Vienna, and early attached himself to the Social Democratic party. He became a leader of Neo-Marxism. He was a deputy from 1907, and, as leader of the Social Democrat party, he repeatedly attacked the Government. He deeply influenced the movement which preceded the fall of the monarchy. After the collapse he became head of the Government, and after the elections had given the Social Democrats and Christian Socialists an overwhelming majority, he formed a coalition ministry, as the leader of which he became the first chancellor of the Austrian republic.

Renner was largely responsible for the decrees of the national assembly which called for the dethronement of the dynasty of Habsburg-Lorraine and the banishment of all members of this house if they did not submit entirely to the laws of the republic, and he was in charge of the negotiations which led to the ex-emperor Charles leaving Austria in March 1919. He was responsible for thwarting the separatist endeavours of the different provinces and the demands which the Communists, supported by their partisans in foreign countries, made with the object of overthrowing the Government. On May 12, 1919, he went to Paris as head of the Austrian delegation to receive the conditions of peace. As the foreign minister, Otto Bauer (*q.v.*), resigned rather than take the responsibility for certain provisions of the treaty, Renner took over the conduct of foreign affairs and signed the Treaty of St. Germaine-en-Laye of Sept. 10, 1919. In Dec. 1919 he visited Paris again to depict Austria's miserable situation to her former enemies and to beg, not without success, for help.

Meanwhile, the first coalition ministry had been succeeded in Oct. 1919 by a second, in which Renner was again chancellor and secretary for foreign affairs. Relations between the Austrian Government and Hungary, which since the régime of the revolution had been succeeded by a reaction, were very strained. Renner, who, as a Social Democrat, was inimical to the reactionary Hungarian Government, refused to grant demands put forward to extradite the Hungarian revolutionaries who had fled to Vienna. This brought him into conflict with the Christian Socialists and their representatives in the Cabinet. The coalition broke up in June; but Renner remained in charge of foreign affairs in the so-called "proportional cabinet," only resigning in Oct. 1920. He continued to take part in the parliamentary debates and the enterprises of the Social Democrat party; but his influence rapidly declined.

His principal works are *Grundlagen und Entwicklungsziele der Österreichisch-ungarischen Monarchie* (1906); *Oesterreichs Erneuerung* (1919); *Die Wirtschaft als Gesamtprozess und die Sozialisierung* (1924). (A. F. P.)

RENNES, a town of western France, formerly the capital of Brittany and now the chief town of the department of Ille-et-Vilaine. Pop. 73,866. Rennes is situated at the meeting of the Ille and the Vilaine and at the junction of several lines of railway connecting it with Paris (232 m. E.N.E.), St. Malo (51 m. N.N.W.), Brest (155 m. W.N.W.). Rennes, the chief city of the Redones, was formerly (like some other places in Gaul) called Condate (hence *Condat*, Condé), probably from its position at the confluence of two streams. In Roman times it was in Lugdunensis Tertia, and became the centre of Roman roads. The oldest chronicles named it *Urbs Rubra* from the bands of red brick in the foundations of its first circuit of walls. Conan le Tort, count of Rennes (late 10th century), subdued the whole province, and his son and successor Geoffrey first took the title duke of Brittany. The dukes were crowned at Rennes, and before entering the city by the Mordelaise gate they had to swear to preserve the privileges of the church, the nobles and the commons of Brittany. In 1356–57 Bertrand du Guesclin saved it from capture by the English. The parlement of Brittany, founded in 1551, held its sessions at Rennes from 1561, they having been previously shared with Nantes. Henry IV. entered the city in state on May 9, 1598. In 1675 an insurrection at Rennes, caused by the taxes imposed by Louis XIV. was cruelly suppressed. The parlement was banished to Vannes till 1689, and the inhabitants punished. At the beginning of the Revolution Rennes was again the scene of bloodshed, caused by the discussion about doubling the third estate for the convocation of the states-general. In Jan. 1789 Jean Victor Moreau (afterwards general) led the law-students in their demonstrations on behalf of the parlement against the royal government. It was the centre of the operations of the Republican army against the Vendeans. The bishopric, founded in the 5th century, in 1859 became an archbishopric, a rank to which it had previously been raised from 1790 to 1802.

The town was for the most part rebuilt of dark granite on a regular plan after the seven days' fire of 1720. The old town or Ville-Haute occupies a hill bounded on the south by the Vilaine, on the west by the canalized Ille. The Vilaine flows in a deep

hollow bordered with quays and crossed by six bridges leading to the new town or Ville-Basse on its left bank. The cathedral of Rennes was rebuilt between 1787 and 1844 on the site of two churches dating from the 4th century. The Renaissance west façade has twin towers. The archbishop's palace occupies in part the site of the abbey of St. Melaine. The Mordelaise gate is a curious example of 15th-century architecture, and preserves a Latin inscription of the 3rd century, a dedication by the Redones to the emperor Gordianus. The finest building in Rennes is the 17th century parliament house, now the law-court.

Rennes is the seat of an archbishop and a prefect, headquarters of the X. army corps and centre of an *académie* (educational division). Its university has faculties of law, science and letters, and a preparatory school of medicine and pharmacy. The town is also the seat of a court of appeal, of a court of assizes, of tribunals of first instance and commerce, of a board of trade-arbitrators and of a chamber of commerce. Tanning, iron-founding, timber-sawing and the production of furniture and wooden goods, flax-spinning and the manufacture of tenting and other coarse fabrics, bleaching and various smaller industries are carried on. Trade is chiefly in butter made in the neighbourhood, and in grain, flour, leather, poultry, eggs and honey.

RENNET: *see* CHEESE; DAIRY FARMING.

RENNIE, JOHN (1761–1821), British engineer, was the youngest son of James Rennie, a farmer at Phantassie, Haddingtonshire, where he was born on June 7, 1761. His first engineering work was the erection of flour mills, but his fame chiefly rests on his achievements in civil engineering. His skill solved the problem of draining and reclaiming extensive tracts of marsh in the eastern counties and on the Solway Firth. As a bridge engineer he built Waterloo, Southwark and London bridges—the last of which he did not live to see completed (*see* BRIDGES: *Construction*). A noteworthy feature in many of his designs was the flat roadway. Among the harbours and docks in the construction of which he was concerned are those at Wick, Torquay, Grimsby, Holyhead, Howth, Kingstown and Hull, together with the London dock and the East India dock on the Thames, and he was consulted by the government in respect of improvements at the dockyards of Portsmouth, Sheerness, Chatham and Plymouth, where the breakwater was built from his plans. He died in London on Oct. 4, 1821, and was buried in St. Paul's.

RENO, the largest city of Nevada, U.S.A., and the county seat of Washoe county; on the Truckee river, 14 m. from the western boundary of the State. It is on Federal highways 40 and 50; has a municipal airport of 160 ac. and is a station on the transcontinental air-mail route; and is served by the Southern Pacific, the Virginia and Truckee, and the Western Pacific railways, and ten motor-stage lines. The population was 12,016 in 1920 (80% native white) and was estimated locally at 18,500 in 1928. The city covers 3 sq.m., at an altitude of 4,500 ft., near the foot of the Sierra Nevada mountains, amid magnificent and varied scenery. It is the financial, educational and professional centre of the State, and the commercial centre for the adjacent districts of California as well as for Nevada. Manufacturing is relatively unimportant, but the 57 plants in the city in 1926 had an output valued at $4,500,000. In the suburb of Sparks, 2·5 m. E. (pop. in 1920: 3,238), are extensive shops of the Southern Pacific railroad. The banking business is large in proportion to the size of the city. Clearings in 1927 amounted to $35,368,959, and debits to individual accounts totalled $112,269,224. The University of Nevada (opened at Elko in 1873 and moved to Reno in 1885) occupies a 60-acre campus on a low plateau overlooking the city. Adjoining the campus is the 60-acre farm of the agricultural experiment station, given by the citizens of Washoe county in 1899, and 4 m. S. of the city is the university stock-farm of 213 acres. The Mackay school of mines was founded in 1907 by Mrs. John W. Mackay and Clarence H. Mackay in memory of John W. Mackay, one of the pioneers of the Comstock lode. Affiliated with the university are the Nevada Agricultural Experiment station (1887), the State Analytical laboratory (1895), the State Hygienic laboratory (1909), the State Laboratory for Pure Food and Drugs and Weights and Measures (1909), the State Veterinary Control Service (1915), and one of the 12 experiment stations of the United States Bureau of Mines, handling all the investigations for the United States on gold, silver, platinum, and the rare metals (1919). Reno is the seat also of the State Hospital for Mental Diseases (1882) and of a general hospital serving a wide area. Because of the relative ease with which a divorce may be secured in Nevada (the law recognizing seven grounds for an absolute decree and requiring only three months' residence before bringing suit) Reno is the temporary residence of many persons from New York and other States with less liberal laws on the subject. About 25 m. S.E. of the city are the famous mining camps of Virginia City and Gold Hill, on the Comstock lode. In 1859 (the year the Comstock lode was discovered) a roadhouse was built on the site of Reno for the accommodation of travellers and freight-teams on the Overland Route and to the goldfields. By 1863 the place had become known as Lake's Crossing, and five years later it was chosen for a station on the Central (now the Southern) Pacific railroad, then building through the Truckee valley. It was named after General Jesse Lee Reno (1823–62), a Federal officer in the Civil War. The town was incorporated in 1879, and was chartered as a city in 1899 and again in 1903. In 1873 and in 1879 it suffered from destructive fires.

RENOIR, FIRMIN AUGUSTE (1841–1919), French painter, was born at Limoges on Feb. 25, 1841. He was the son of a tailor. At 13 he was apprenticed to a manufacturer of porcelain, and in painting on china he acquired a taste for pure and transparent colour and subtle brushwork. After earning some money in painting fans and blinds he entered the studio of Gleyre, where he became the friend of Sisley and Monet. He was inspired by Courbet to study nature; he was interested in Delacroix's colour technique; and the work of Monet and Corot appealed to him. In his early work he followed, with pronounced modern modifications, certain traditions of the French 18th century school. In the work of a later period colour was made subservient to form under the influence of Ingres, and his search for volume and form induced him at the end of his life to take up modelling. In the '70s he threw himself into the impressionist movement and became one of its leaders. Renoir tried his skill in almost every genre—in portraiture, landscape, flower-painting, scenes of modern life and figure subject; he excelled in painting nude figures of women. His art breathes sensuality, transfigured by lyrical feeling and plastic sense. His finest works rank among the masterpieces of the modern French school. Among these are some of his nude "Bathers," the "Rowers' Luncheon," the "Ball at the Moulin de la Galette," "The Box," "The Terrace," "*La Pensée*," and the portrait of "Jeanne Samary." He is represented in the Caillebotte room at the Luxembourg, in the collection of M. Durand-Ruel, and in most of the collections of impressionist paintings in France, in the United States, in Germany and in the Tate gallery, London. Renoir died on Dec. 17, 1919, at Cagnes in Provence, where he had settled in 1900.

See A. Vollard, *La Vie et L'oeuvre de Pierre-Auguste Renoir* (1919) and *Impressionism;* F. Fosca, *Renoir* (Eng. trans., 1924).

RENOUF, SIR PETER LE PAGE (1822–1897), Egyptologist, was born in Guernsey, on Aug. 23, 1822. He was educated at Elizabeth College there, and proceeded to Oxford, which, upon his becoming a Roman Catholic, under the influence of Dr. Newman, he quitted without taking a degree. He took an active part in church controversy, and his treatise (1868) upon the condemnation of Pope Honorius for heresy by the council of Constantinople in A.D. 680 was placed upon the index of prohibited books. After holding various educational posts he became in 1866 Keeper of Oriental Antiquities in the British Museum, in succession to Samuel Birch. He was also elected in 1887 president of the Society of Biblical Archaeology, to whose *Proceedings* he contributed, among other important papers, the translation of *The Book of the Dead*, with a commentary. He retired in 1891, and died in London on Oct. 14, 1897.

RENOUVIER, CHARLES BERNARD (1815–1903), French philosopher, was born at Montpellier on Jan. 1, 1815, and died on Sept. 1, 1903. His two leading ideas are a dislike for the Unknowable, and a reliance on the validity of personal experience.

The former accounts for his acceptance of Kant's phenomenalism, combined with rejection of the "thing in itself." It accounts, too, for his polemic on the one hand against a Substantial Soul, a Buddhistic Absolute, an Infinite Spiritual Substance; on the other hand against the no less mysterious material or dynamic substratum by which naturalistic Monism explains the world. He holds that nothing exists except presentations, which are not merely sensational, and have an objective aspect no less than a subjective. To explain the formal organization of our experience he adopts a modified version of the Kantian categories. The insistence on the validity of personal experience leads Renouvier to a yet more important divergence from Kant in his treatment of volition. Liberty, he says, in a much wider sense than Kant, is man's fundamental characteristic. Human freedom acts in the phenomenal, not in an imaginary noumenal sphere. Belief is not intellectual merely, but is determined by an act of will affirming what we hold to be morally good. In his religious views Renouvier makes a considerable approximation to Leibnitz. He holds that we are rationally justified in affirming human immortality and the existence of a finite God who is to be a constitutional ruler, but not a despot, over the souls of men. He would, however, regard atheism as preferable to a belief in an infinite Deity. His chief works are: *Essais de critique générale* (1854–64); *Science de la morale* (1869); *Uchronie* (1876); *Esquisse d'une classification systématique des doctrines philosophiques* (1885–86); *Philosophie analytique de l'histoire* (1896–97); *Histoire et solution des problèmes métaphysiques* (1901); *Victor Hugo: Le Poète* (1893); *Le Philosophe* (1900); *Les Dilemmes de la métaphysique pure* (1901); *Le Personnalisme* (1903); *Critique de la doctrine de Kant* (1906, published by L. Prat).

See L. Prat, *Les Derniers entretiens de Charles Renouvier* (1904); M. Ascher, *Renouvier und der französische Neu-Kriticismus* (1900); E. Janssens, *Le Néocriticisme de C. R.* (1904); A. Darlu, *La Morale de Renouvier* (1904); G. Séailles, *La Philosophie de C. R.* (1905); A. Arnal, *La Philosophie religieuse de C. R.* (1907).

RENSSELAER, a city of Rensselaer county, New York, U.S.A., on the east bank of the Hudson river, opposite Albany. It is served directly by the Boston and Albany and the New York Central railways, is a part of the deep-water port of Albany (under development, 1928) and shares in the other transportation facilities of Albany (*q.v.*). Pop. (1920) 10,823 (90% native white). It has large railroad shops and other important manufacturing industries, with an output in 1925 valued at $11,942,630. Among the leading manufactures are felts and blankets, shoddy, aspirin and other pharmaceutical products, dyes, size and chemicals. A settlement called Greenbush was established here in 1631, on the large tract known as Rensselaerwyck. In 1810 a square mile of land within the present city limits was acquired by a speculator, who divided it into lots and offered them for sale, and in 1815 the village was incorporated. In 1897 it was chartered as a city under its present name.

RENT. Various species of rent appear in Roman law (*q.v.*). In English law rent is a certain and periodical payment or service made or rendered by the tenant of a corporeal hereditament and issuing out of (the property of) such hereditament. Its characteristics, therefore, are (1) certainty in amount; (2) periodicity in payment or rendering; (3) the fact that rent is *yielded* and is, therefore, said "to lie in *render*," as distinguished from *profits à prendre* in general, which are taken, and are, therefore, said to lie in *prendre;* (4) that it must issue out of (the profits of) a corporeal hereditament. A rent cannot be reserved out of incorporeal hereditaments such as advowsons (Co. *Litt.* 47a, 142a). But rent may be reserved out of estates in reversion or remainder (*see* REAL PROPERTY) which are not purely incorporeal. It is not essential that rent should consist in a payment of money. Apart from the rendering of services, the delivery of hens, horses, wheat, etc., may constitute a rent. But at the present day, rent is generally a sum of money paid for the occupation of land. It is important to notice that this conception of rent was attained at a comparatively late period in the history of the law. The earliest rent seems to have been a form of personal service, and was fixed by custom. Rent service is the oldest kind of existing rent. It is the only one to which the power of distress attaches at common law, giving the landlord a preferential right over other creditors exercisable without the intervention of judicial authority (*see* DISTRESS). The increasing importance of socage tenure, arising in part from the convenience of paying a certain amount, whether in money or kind, rather than comparatively uncertain services, led to the gradual evolution of the modern view of rent as a sum due by contract between two independent persons.

Classes of Rents.—Rents, as they now exist in England, are divided into two great classes—rent service and rent charge. A rent service is so called because by it a tenure by means of service is created between the landlord and the tenant. The service is now represented by fealty, and is nothing more than nominal. Rent service is said to be incident to the reversion—that is, a grant of the reversion carries the rent with it (*see* REMAINDER). A power of distress is incident at common law to this form of rent. A rent charge is a grant of an annual sum payable out of lands in which the grantor has an estate. It may be in fee, in tail, for life—the most common form—or for years. A rent charge may also be granted out of another rent charge (Law of Property Act, 1925, s. 7, 122 [1]). A rent charge must be created by deed or will, and might be either at common law or under the Statute of Uses (1536). As from Jan. 1, 1926, a rent charge may be created or reserved without the intervention of a use (Law of Property Act, 1925, ss. 65, 187). The grantor has no reversion, and the grantee had at common law no power of distress, though such power was given him by the instrument creating the rent charge. Annual sums charged on land by way of rent charge may be recovered (*a*) if unpaid for 21 days, by distress; (*b*) if unpaid for 40 days, by entry into possession of the land and appropriation of income, and/or demise. By s. 45 of the Conveyancing Act, 1881, a power of redemption of certain perpetual rents in the nature of rent charges is given to the owner of the land out of which the rent issues. Rent charges granted since April 26, 1855, otherwise than by marriage settlement or will for a life or lives or for any estate determinable on a life or lives were required, in order to bind lands against purchasers, mortgagees or creditors, to have been registered in the Land Registry in Lincoln's Inn Fields (Judgments Act, 1855). After 1925, however, rent charges of this character became equitable interests only, and as such are overreached by conveyances to purchasers of a legal estate in lands (Law of Property Act, 1925, s. 2). There was no need, therefore, to provide for the registration of such rent charges, and the Land Charges Act, 1925, enacted that after Jan. 1, 1926, they should not be entered in the register of annuities (s. 4 [1]). Rent charges in possession charged on land perpetually or for a term of years absolute are "legal estates," registrable as such under the Land Registration Act, 1925 (ss. 2, 3, viii., xxv.); and certain classes of rent charge may be entered in the register of land charges under the Land Charges Act, 1925 (s. 10). Rent charges are barred by nonpayment or non-acknowledgment for 12 years (Limitation Act, 1874). The period of limitation for arrears of rent is six years. As to the colonies *see* Burge, *Col. and For. Laws* (by Bewes, iv., pt. 2, 460).

Forms of rent charge of special interest are *tithe rent charge* (*see* TITHES), and the rent charges formerly used for the purpose of creating "faggot votes." The device was adopted of creating parliamentary voters by splitting up freehold interests into a number of rent charges of the annual value of 40s., so as to satisfy the freeholders' franchise. But such rent charges were rendered ineffective by the Representation of the People Act, 1884, s. 4, which enacted (subject to a saving for existing rights and an exception in favour of owners of tithe rent charge) that a man should not be entitled to be registered as a voter in respect of the ownership of any rent charge.

A rent charge reserved without power of distress is termed a *rent-seck* (*reditus siccus*) or "dry rent," from the absence of the power of distress. But, as power of distress for *rents-seck* was given by the Landlord and Tenant Act, 1730, the legal effect of such rents has been since the act the same as that of a rent charge.

Other Varieties of Rent.—*Rents of assize* or *quit rents* are a

relic of the old customary rents. They are presumed to have been established by usage, and cannot be increased or diminished. Provision was made in 1922 for the extinction after 1925 of quit rents and other manorial incidents (Law of Property Act, 1922, ss. 138, 144).

Fee farm rents are rents reserved on grants in fee. They, like quit rents, now occur only in manors, unless existing before the statute of *Quia Emptores* or created by the Crown (*see* REAL PROPERTY). A rent which is equivalent or nearly equivalent in amount to the full annual value of the land is a *rack rent*. As to ground rent, *see* GROUND RENT. A *dead rent* is a fixed annual sum paid by a person working a mine or quarry, in addition to royalties varying according to the amount of minerals taken.

The object of a dead rent is twofold—first, to provide a specified income on which the lessor can rely; secondly (and this is the more important reason), as a security that the mine will be worked, and worked with reasonable rapidity. *Rents in kind* still exist to a limited extent. All *peppercorn*, or nominal, rents seem to fall under this head. The object of the peppercorn rent is to secure the acknowledgment by the tenant of the landlord's right. In modern building leases a peppercorn rent is sometimes reserved as the rent for the first few years. *Labour rents* are represented by those cases, not unfrequent in agricultural leases, where the tenant is bound to render the landlord a certain amount of team work or other labour as a part of his rent.

As to the apportionment of rents, *see* APPORTIONMENT, and as to the rent of apartments, etc., *see* LODGER AND LODGINGS.

Payment of Rent.—Rent is due in the morning of the day appointed for payment, but a tenant is not in arrears until after midnight on that day. Rent made payable in advance by agreement between a landlord and his tenant is called *forehand rent*. It is not uncommon in letting a furnished house, or as to the last quarter of the term of a lease of unfurnished premises, to stipulate that the rent shall be paid in advance. As soon as such rent is payable under the agreement the landlord has the same rights in regard to it as he has in the case of ordinary rent. Where a cheque in payment of rent is lost in the course of transmission through the post, the loss falls on the tenant, unless the landlord has expressly or impliedly authorized it to be forwarded in that way: and the landlord's consent to take the risk of such transmission will not be inferred from the fact that payments were ordinarily made in this manner in the dealings between the parties. A tenant may deduct from his rent (i.) the "landlord's property tax" (on the annual value of the premises for income tax purposes), which is paid by the tenant, if the statute imposing the tax authorizes the deduction (which should be made from the rent next due after the payment); (ii.) taxes or rates which the landlord had undertaken to pay but had not paid, payment having thereupon been made by the tenant; (iii.) payments made by the tenant which ought to have been made by the landlord, *e.g.*, rent due to a superior landlord; (iv.) compensation under the Agricultural Holdings Act, 1923 (s. 37), and Landlord and Tenant Act, 1927 (s. 11 [2]).

A landlord's main remedy for non-payment of rent is *distress* (*q.v.*). Besides distress the landlord has his ordinary remedy by action. In addition, special statutory remedies are given in the case of tenants holding over after the expiration of their tenancy (*see* EJECTMENT). Under the Rent Restriction Acts, 1920–25, landlords of dwelling houses to which these statutes apply were prevented during their continuance from effectually raising the rents above specified limits, and except in certain cases from recovering possession on the termination of the tenancy. The act of 1920 expired in England on Dec. 25, 1927, and in Scotland on May 28, 1928. The provisions of Pt. II. of the act of 1923 continue in force for five years from the expiration of the act of 1920. (*See* further LANDLORD AND TENANT.)

Under the Landlord and Tenant Act, 1927, the landlord of trade premises may offer a renewal of the tenancy at such rent as, failing agreement, the statutory tribunal may consider reasonable, as an alternative to compensation for improvements (s. 2 [1] [d]) or goodwill (s. 4 [1]). The tenant of such premises may also apply for a new lease at a rent similarly approved (s. 5).

Scotland.—Rent is properly the payment made by the tenant to the landlord for the use of lands held under lease (*see* LANDLORD AND TENANT). In agricultural tenancies the legal terms for the payment of rent are at Whit Sunday after the crop has been sown, and at Martinmas after it has been reaped. But a landlord and tenant may substitute conventional terms of payment, either anticipating (*fore* or *forehand rent*) or postponing (*back* or *backhand rent*) the legal term. The rent paid by vassal to superior is called *feu-duty* (*see* FEU). Its nearest English equivalent is the *fee farm rent*. The remedy of distress does not exist in Scots law. Rents are recovered (i.) by summary diligence, proceeding on a clause, in the lease, of consent to registration for execution; (ii.) by an ordinary petitory action; (iii.) by an action of "maills and duties" (the rents of an estate in money or grain: "maills" was a coin at one time current in Scotland) in the Sheriff Court or the Court of Session; and (iv.) in non-agricultural tenancies by procedure under the right of hypothec, where that still exists; the right of hypothec over land exceeding two acres in extent let for agriculture or pasture was abolished as from Nov. 11, 1881; it was also excluded, by the House-letting and Rating (Scotland) Act, 1911 (s. 10), in lets to which that act applies, from all bedding material and all implements of trade used by the occupier and his family and from furniture selected by him up to £10 value (*see* DISTRESS; HYPOTHEC); (v.) by action of removing (*see* EJECTMENT). Arrears of rent prescribe after the expiration of a period of five years reckoned from the time of the tenant's removal from the land.

Labour or service rents were at one time very frequent in Scotland. The events of 1715 and 1745 showed the vast influence over the tenantry that the great proprietors acquired by such means. Accordingly acts of 1716 and 1746 provided for the commutation of services into money rents. Such services may still be created by agreement, subject to the summary power of commutation by the sheriff given by the Conveyancing Act, 1874 (ss. 20, 21). They will no longer be eligible from and after Jan. 1, 1935 (Conveyancing [Scotland] Act, 1924, s. 12 [7]). The Conveyancing (Scotland) Act, 1924, provides (s. 12) for the abolition or commutation of feu-duties payable in grain or other fungibles.

United States.—The law is in general accordance with that of England, apart from statute. The tendency of modern State legislation is unfavourable to the continuance of distress as a remedy. In the New England States, attachment on mesne process has, to a large extent, superseded it. Alabama, Colorado, Missouri, Montana, North Carolina and Oklahoma have refused to recognize the right of distress upon the ground that the landlord's rights have been secured by the substitution of other remedies. In the District of Columbia, Indiana, Minnesota, New York and Wisconsin it has been abolished by statute. "In those (states) in which it still exists, it has been modified by statutes, the general tendency of which is more or less to withdraw the control of the proceedings from the landlord and to rest it in public officials, thus assimilating it to the process of attachment." (2 Tiffany, Landlord and Tenant, section 325.)

Other Countries.—Under the French Code Civil (art. 2,102) the landlord is a privileged creditor for his rent. If the lease is by authentic act, or under private signature for a fixed term, he has a right over the year's harvest and produce, the furniture of the house and everything employed to keep it up, and (if a farm) to work it, in order to satisfy all rent due up to the end of the term. If the lease is not by authentic act nor for a specified term, the landlord's claim is limited to the current year and the year next following (*see* law of Feb. 12, 1872). The goods of a sub-lessee are protected: and goods bailed or deposited with the tenant are in general not liable to be seized. The French law is in force in Mauritius, and has been reproduced in substance in the Civil Codes of Quebec (arts. 2,005 *seq.*) and St. Lucia (arts. 1,888 *seq.*). There are analogous provisions in the Spanish Civil Code (art. 1,922). The subject of privileges and hypothecs is regulated in Belgium by a special law of Dec. 16, 1851; and in Germany by ss. 1,113 *seq.* of the Civil Code. The law of British India as to rent (Transfer and Property Act, 1882) and distress

(*cf., e.g.,* Act 15 of 1882) is similar to English law. The British dominions generally tend in the same direction. See, *e.g.,* New South Wales (the consolidating Landlord and Tenant Act, 1899, and Act 66 of 1915); Union of South Africa (Act 30 of 1921); Newfoundland (Act 4 of 1899); Ontario (Act 1 of 1902, s. 22, giving a tenant five days for tender of rent and expenses after distress); Jamaica (Law 17 of 1900, certification of landlord's bailiffs); Queensland (Act 15 of 1904). English rent restriction legislation was followed in British India (*e.g.,* Bombay, No. 3 of 1925; Burma, No. 1 of 1925) and in many of the colonies and dominions (*e.g.,* Hongkong, No. 8 of 1925; Malta, No. 1 of 1925; New Zealand, No. 3 of 1925).

RENT: IN ECONOMICS. In economics, rent is the name given to the income which the owner of a productive instrument gets by using it himself or by exacting a payment from another user. Much of the importance of the general theory of rent in economics comes from its application to the special case of income derived from land ownership. In the case of the incomes yielded by the ownership of reproducible instruments of production the principle of rent is subordinate, in the long run, to the principles which govern the rate of interest on capital, for the supply of such instruments will be maintained and increased if, but only if, the prospective return is sufficient to induce the investment of capital. At any given time, however, the income-yielding power of reproducible instruments of production is determined, not by what they cost, but by the value of their productive uses. That is, it is governed by the laws of rent. The specific hypothesis upon which the significance of the principle of rent depends is that the supply of the productive instruments which yield rent may be assumed to be given or fixed, so that the question remains only of how they may best be used.

Rent is generally held to have two distinguishing characteristics: first, it is a differential or graded return; second it is a surplus above costs. That it is a differential return depends upon the circumstance that productive instruments are described or measured in units (*e.g.,* acres) which are not themselves units of productive efficiency. It is obvious that if one acre of agricultural land is better (more fertile or nearer to the market) than another it will command a larger rent. It is also obvious that the rent which any given piece of land commands may be taken to be a measure of its differential superiority over land which just falls short of being good enough to be worth using. That rent may be regarded as a surplus over costs is a consequence of the circumstance that the supply of rent-yielding instruments is taken as given. Even if they were produced or improved (as land is improved) at a cost in the past, their past costs have no relevance to the practical question of how and for what purposes the instruments shall be used. The only costs which need to be taken into account are the costs of using them.

Rent's Relation to Product.—Why, then, should rent be paid? The reason is that rent-yielding productive instruments, including rent-yielding land, exist in limited quantities, in the sense that if any one unit of them were withdrawn from use the aggregate product would be smaller. The rent of a given piece of land or of a given farm tends to be approximately equal to the value of the amount of product which is dependent upon using it. This amount can be determined by comparing the product which the given piece of land or farm will yield under proper cultivation with the product which could be got by employing the same amount of capital and labour on the best land which is not good enough to yield a rent (*i.e.,* at the "extensive margin of cultivation") or by employing it in cultivating rent-yielding lands more intensively (*i.e.,* at the "intensive margin of cultivation"). When the supply of a particular class of rent-yielding productive agents cannot be increased as rapidly as the demand for the products which they yield increases, they will command higher rents. Furthermore, unless there are compensating improvements in productive technique, production can be increased under such circumstances only by using instruments which had previously been below the level of profitable use or by making more intensive use of the latter instruments, *i.e.,* by increasing the labour and other types of instruments used in conjunction with them. Whichever method is followed, increasing costs are encountered. This circumstance is the basis of the doctrine that with a fixed supply of land an increased agricultural product can be had only at the expense of a more than proportionate outlay of labour and capital—a doctrine to which the name, "law of diminishing returns," has been given.

When economists refer to some other form of income or gain, not derived from the ownership of land or of other productive instruments, as rent, they generally mean either that it may be looked upon as a differential return or that it may be conceived to be a surplus above costs. Thus, "rent of ability" is a name sometimes given to the differential element in personal earnings. "Entrepreneur's rent" denotes the profits of an ably-managed and successful enterprise, conceived of as a differential above the return secured by a marginal undertaking which is barely able to meet its costs. "Consumer's rent" is the difference between the amount which the consumer pays and the value which he attaches to what he buys, as measured by the maximum amount which he would have been willing to pay if required. Similarly, "producer's rent" is the difference between what the state of the market enables the producer to get for his goods and the amount which would have sufficed to induce him to produce them. (*See* also ECONOMICS and LAND.) (A. Yo.)

RENTON, a manufacturing town of Dumbartonshire, Scotland. Pop. (1921) 4,996. It is situated on the Leven, 2 m. N.N.W. of Dumbarton by the L.M.S. & L.N.E. railways. The leading industry is Turkey red dyeing, and calico-printing and bleaching are also carried on. The town was founded in 1782 by Mrs. Smollett (sister of Tobias Smollet); it was named after Cecilia Renton who became her daughter-in-law.

RENWICK, JAMES (1662–1688), Scottish covenanting leader, was born at Moniaive, Dumfriesshire, on Feb. 15, 1662, the son of a weaver. Educated at Edinburgh University, he joined the Cameronians about 1681. After studying theology at Groningen he was ordained a minister in 1683. Returning to Scotland, he became one of the field-preachers and was declared a rebel by the privy council. He was largely responsible for the "apologetical declaration" of 1684 by which he and his followers disowned the authority of Charles II.; the privy council replied by ordering every one to abjure this declaration on pain of death. Renwick refused to join the rising under the earl of Argyll in 1685; in 1687, when the declarations of indulgence allowed some liberty of worship to the Presbyterians, he and his followers, often called Renwickites, continued to hold meetings in the fields, which were still illegal. A reward was offered for his capture, and early in 1688 he was seized in Edinburgh. He refused to apply for a pardon and was hanged on Feb. 17, 1688. Renwick was the last of the covenanting martyrs.

See R. Wodrow, *History of the Sufferings of the Church of Scotland,* vol. iv. (Glasgow, 1838); and A. Smellie, *Men of the Covenant* (1904); also Renwick's life by Alexander Shields in the *Biographia Presbyteriana* (1827).

REP, REPP or **REPS,** cloth made of silk, wool or cotton. The name is said to have been adopted from the French *reps,* a word of unknown origin; it has also been suggested that it is a corruption of "rib." It is woven in fine cords or ribs across the width of the piece. In various forms it is used for dresses, and to some extent for ecclesiastical vestments. In wool and cotton it is also used for upholstery purposes.

REPARATIONS AND THE DAWES PLAN. The Treaty of Versailles in June 1919 did not directly deal with the

question of reparations in its financial aspects. It placed on Germany the moral responsibility for all damage done to the population of the Allied countries (*see* VERSAILLES, TREATY OF). It set up a Reparation Commission to translate the treaty into actual figures by assessing the damage, to lay down the method and times of payment, and to come to its determination by May 1921.

I. FROM THE TREATY TO THE LONDON CONFERENCE

San Remo to Spa.—In April and May 1920 the Allies (Great Britain, Belgium, France, Italy and Japan) met in conferences at San Remo and Hythe, and discussed the methods of computing the liability of the enemy countries and also of sharing the proceeds. The Supreme Council had their own experts making computations, the Reparation Commission in the meantime continuing their investigation of the damages and mode of collection. (At this stage there was a tentative agreement for France to pay her debt as and when she received payment from Germany.) In June 1920 at Boulogne, statements of actual amounts emerged. A minimum annuity of 3,000 million gold marks for 35 years, with a maximum aggregate of 269,000 million, was proposed; the actual amount to be settled by economic conditions. The costs of military occupation were to be a first charge on the "deliveries in kind," of which coal was the chief, and customs and natural resources were to be employed as guarantees. At the important Spa Conference—July 1920 (following a meeting of experts at Brussels) and with Germany and Portugal represented, they discussed proposals for Germany to pay 42 annuities aggregating 240,000 million gold marks; coal deliveries were fixed at two million tons monthly forthwith. There was an actual agreement, which has survived, as to the division of the proceeds as follows:—

	%		%
France	52	Belgium	8
British empire	22	Japan and Portugal	1·50
Italy	10	Others (Greece, Rumania, etc.)	6·50

A priority for 2,000 million gold marks was given to Belgium. At this conference the Germans expressed their views on the importance of territorial integrity, and the necessity for first securing an "export surplus" before making any payment in cash or kind.

The Paris Decisions.—In Dec. 1920 financial experts met in Brussels and made recommendations to the Supreme Council, and on Jan. 29, 1921, the Allies reached the "Paris decisions." The fixed annuities were to be:—

(*a*) 2 annuities of 2 milliard gold marks.
(*b*) 3 annuities of 3 milliard gold marks.
(*c*) 3 annuities of 4 milliard gold marks.
(*d*) 3 annuities of 5 milliard gold marks reached by May 1932.
(*e*) 31 annuities of 6 milliard gold marks reached by May 1963.

These 42 annuities were to be paid from 1921 equal to 12% of the value of Germany's exports. Supervision of Customs and occupation of the Ruhr in event of failure were discussed. In Feb. 1921 the various Allies had submitted their "claim" to the Reparation Commission. For damages alone the claims totalled about 100 milliard gold marks (1 milliard gold marks = 50 million sterling), but including other claims the total was about 225 milliard gold marks, or, say 11,600 million sterling. In March 1921 at the first London Conference, Germany proposed 1,500 million pounds in cash over 30 years, with credit for 1,000 millions already paid. In April through the United States a vastly increased offer was made with stipulations about the return of surrendered territory.

II. FROM THE LONDON CONFERENCE TO THE DAWES COMMITTEE

The London Ultimatum.—On April 27, 1921, the Reparation Commission announced their "assessment" as 132 milliard gold marks (6,600 million sterling, or 58% of the claim). The decision did not refer to Germany's "capacity to pay" at all—it was a computation of legal liability, on the terms of the treaty. The Allies decided that this was to be paid in annuities of £100,000,000, plus 26% of German exports. Three series of bonds were to be issued, two in 1921, (*a*) 600 million pounds, (*b*) 1,900 million, and the balance as series (*c*) 4,100 million at such time as the Reparation Commission might determine. These bonds were to bear 5% interest, and 1% amortisation.

Upon this report the London Conference issued an ultimatum (May 5, 1921), giving effect to those decisions and also deciding that deliveries of coal and materials, etc., were to continue, Germany being given credit for the appropriate values. A Committee of Guarantees was to be set up to report upon the German fiscal revenues and to supervise the actual machinery for delivering funds, etc. Occupation of the Ruhr Valley and penalties in regard to customs and other revenues were proposed in case Germany failed to accept the terms.

The first payment of one milliard gold marks due by Sept. 1, 1921, was actually paid over, partly out of foreign balances which had accumulated prior to May, partly by sales of paper marks on the Exchange, and partly by temporary advances from an international group of banks. Deliveries in kind after May covered the Nov. instalment. The export tax, a quarter of a milliard, was paid for the first quarter.

In Oct. certain details were agreed between the French and German ministers at Wiesbaden in regard to deliveries in kind for France, in place of the 26% export tax, and the practical details of these agreements were subsequently accepted by the other Governments concerned.

Difficulties began to arise almost immediately in regard to the payment of the annuities. In Aug. 1921, Mr. J. M. Keynes first published his famous prediction that the instalments of Jan. and Feb. 1922 might be covered out of further "deliveries," temporary advances and foreign assets of German industrialists. But the payment of April 1922 would present more difficulty. "Sometime between Feb. and Aug. 1922 Germany will succumb to an inevitable default. This is the maximum extent of our breathing space." In Dec. 1921 the German Government notified the Reparation Commission that their attempt to raise a foreign loan having been abortive, they could not raise in addition to deliveries in kind, more than 200 million gold marks on account of the payments for Jan. and Feb. 1922. There were conferences of the Allied prime ministers at London in Dec. 1921 and Cannes in Jan. 1922, as a result of which the Commission granted a moratorium to Germany from the amounts due under the schedule of payments, accepting payments of 31 million gold marks every ten days. It was laid down that Germany was to present plans for balancing the budget, stabilizing the currency and preventing exports of capital. Shortly after, Germany made an offer of 720 million gold marks per annum in addition to 1,450 million by deliveries in kind, agreeing to balance the budget, increase the coal and sales tax and check inflation by a compulsory loan. Germany asked for a reduction of the treaty payments to an amount within her capacity.

At the Paris Conference in March (March 11, 1922) the Reparation Commission was asked to consider the possibility of an external loan, but an international committee of bankers, which met at the end of May, concluded that such a loan was impossible so long as Germany's external liabilities remained at the figure arranged. Meanwhile in March 1922 the Reparation Commission agreed to a payment of 720 million gold marks inclusive, as the cash payment, suspending the schedule of payments in the meantime, and laying down that Germany should impose her new taxation at once or be exposed to the "sanctions" of the London Agreement.

In Aug. 1922, after Germany had asked for 2½ years' moratorium, the third London Conference and the Reparation Commission suspended cash payments, and agreed to accept the balance of instalments for 1922 in six months' bills at 4½%. It was laid down that further default would bring about the seizure of productive guarantees. In Nov. the German Government replied requesting a definite moratorium and the revision of the total payments. They asked for time to carry out the plans for stabilization recommended by the currency experts.

The British Proposals of Jan. 1923.—In Jan. 1923 there

was a Conference in Paris of the prime ministers, when a somewhat complicated proposal was put forward by Britain for an issue of 50 milliards of "A" bonds maturing in 1954, with interest deferred entirely for the first four years, and 1% for the next four down to the end of 1930. There was to be an issue of "B" bonds, to be definitive unless Germany proved to a tribunal before April 1933 her inability to meet the payment, and deliveries in kind were to be continued for determined amounts, with any excess to be set off against the bond interest. This plan was linked up with the question of inter-Allied debts and their cancellation. Germany was to agree to the currency stabilization plan recommended by the foreign experts a few weeks previously. She was to balance her budget within two years and accept a foreign finance supervision which should supersede the Reparation Commission in all executive functions. There were also conditions as to Germany's forfeiture of customs and the allocation of loans, issued in the Allied markets, to the redemption of the bonds.

At the same time the French prime minister put forward a proposal to adhere to the capital sums determined in May 1921, with a moratorium of two years, giving Germany the power to repay under discount. The customs were to be retained as productive pledges, and the Reparation Commission were to take control of German finance. France agreed that if any of her debts to the Allies were remitted, she would be prepared to consider the question of reducing Germany's total indebtedness.

The Ruhr Occupation.—During the comparative deadlock that followed, France began to carry out her proposals for the occupation of the Ruhr. In the immediate ensuing period considerable doubt existed as to the effect of the occupation upon reparations, but by May and June the Germans had become thoroughly alarmed, and their proposals for the evacuation of the Ruhr Valley and the restoration of Germany's economic freedom, were contained in special German notes the net effect of which was that the capital debt should be fixed at 30 milliard gold marks, of which 20 milliards would be covered by an international loan in July 1927, 5 milliards two years later, and 5 milliards by July 1931, the proceeds to be given over to the Reparation Commission. As guarantees for the service of these loans they were to mortgage the railways for 10 milliards, yielding 500 million gold marks per year; 500 million from the general mortgage on the industries and natural resources of Germany and, thirdly, the pledge of their consumption taxes, *i.e.*, luxury, tobacco, beer, wine and sugar, to an amount probably exceeding 200 million gold marks.

Germany suggested an international conference to determine her capacity to make further payments. The effect of inflation and the general disintegration of German finance, became very marked, and Germany's whole constitutional fabric was in grave danger. (*See* GERMANY: *Economic and Social Conditions.*)

Appointment of the Dawes Committee.—Towards the end of the year active steps were being taken to set up an international committee of experts to consider Germany's position, and to make proposals for stabilizing the currency and balancing the budget. The credit for this proposal has been variously assigned to Mr. Hughes of the United States, to Sir John (afterwards Lord) Bradbury on the Reparation Commission, and to the International Chamber of Commerce Conference at Rome. The representatives of this Committee were in form chosen by the Reparation Committee and appointed by them. But their selection was made a matter of Government interest in each country, there being two representatives from France, Belgium, Italy, Great Britain and the United States respectively. The chairmanship was put into the hands of the United States in the person of General Dawes, and this Commission became afterwards known as the "Dawes Committee," and its report as the "Dawes report." The personnel of the Committee was as follows: United States—General Charles G. Dawes, Owen D. Young; Great Britain—Sir Robert Kindersley, G.B.E., Sir Josiah Stamp, K.B.E.; France—J. Parmentier, Professor Alex; Italy—Dr. Alberto Pirelli, Professor Flora; Belgium—E. Franqui, Baron Houtart. (There was a second committee, under the chairmanship of the Rt. Hon. Reginald McKenna, set up "to consider the means of estimating the amount of German exported capital and of bringing it back to Germany.")

III. THE DAWES REPORT

The Dawes Committee began its meetings in Paris on Jan. 14, 1924, and reported on April 9, 1924. Although neither the evacuation of the Ruhr nor the question of reparations was mentioned in the terms of reference they really were in the forefront of the task. In the first place, so long as the occupation of the Ruhr continued and Germany was not a complete fiscal unit, she had not entire control of her receipts and expenditure, and there could be no guarantee of a balanced budget. In the second place, the reparation liabilities under the treaty figured amongst the budgetary expenses, and if in excess of budgetary possibilities, made it impossible to guarantee that steps taken for the stability of the currency would be permanent and effective. The question of reparations, therefore, figured prominently in the report.

General Principles.—The report adopted a business attitude and considered political factors only in so far as they affect the practicability of the plan. It sought the recovery of debt, not the imposition of penalties, regarding the payment of that debt by Germany as her necessary contribution to repairing the damage of the war. The committee recommended it as in the interest of all parties to carry out this plan in good faith, these assurances being paramount having regard to the temper ruling at that time, and the suspicion of motives. They avoided the political guarantees which had been so prominent hitherto and proposed only economic ones. They were emphatic that for success in stabilizing currency and balancing budgets, Germany needed the resources of German territory as defined by the Treaty of Versailles, and free economic activity therein. On the vexed question of military "sanctions" and occupation which were strictly beyond their terms of reference, they confined themselves to stating "within the unified territory, the plan requires that, when it is in effective operation:—

1. If any military organization exists, it must not impede the free exercise of economic activities;
2. There shall be no foreign economic control or interference other than that proposed by the plan."

The report treated stabilization of currency and the balancing of budgets as interdependent, though provisionally separable for examination, and insisted that currency stability could only be maintained if the budget were normally balanced; while the budget could only be balanced if a stable and reliable currency existed. Both were needed to enable Germany to meet her internal requirements and treaty payments. They laid stress upon Germany's economic future as indicated by her productive power, plant capacity, increasing population, technical skill, material resources and eminence in industrial science.

Organization of the Reichsbank.—In their proposal for the stabilizing of the currency they suggested that a new bank be set up or the Reichsbank reorganized. The main characteristics of the bank were given:—

1. To issue notes on a basis stable in relation to gold, with an exclusive privilege;
2. To serve as a bankers' bank, establishing the official rate of discount;
3. To act as the Government banker, but free of Government control;
4. Advances to Government to be strictly limited;
5. To hold on deposit reparation payments;
6. The capital of the bank will be 400 million gold marks;
7. It will be directed by a German president and managing board, who can be assisted by a German consultative committee;
8. The due observance of its statutes will be further safeguarded by a General Board, of which half of the members, including a commissioner, will be foreign.

They were emphatic that even granted full economic and fiscal sovereignty, balancing the budget would necessitate a period of relief from reparation payments, though the pressure of political interests was too great to allow of a complete suspension of deliveries in kind.

Although the budget might be balanced without the total *capital* debt of Germany being fixed, they maintained it could not be

continuously balanced if there were any uncertainty as to the maximum *annual* charge that would fall upon it for some years, on a basis clearly prescribed in advance. The report deferred to the principle that the German people ought to bear a burden commensurate with that in the Allied countries, and they claimed to apply the principle "to the full limit of practicability."

The Transfer Committee.—A transfer committee of an international constitution was set up to control the "delivery" programme, to receive the payments in marks in Germany, and to be responsible for the extent to which, and the way in which, these sums were transferred abroad in foreign currencies. Thus the mistake of forcing Germany beyond the economic point in the purchase of foreign currencies, which had been made in the past, was guarded against for the future. No attempt was made, as it was outside the terms of reference, to assess the *length* of time during which these payments should be made, or the total amount of the Reparation debt, but it was clear that the amount to be paid in the standard year, viz., 2½ milliards, would not do more than pay the interest on a portion of the liability imputed under the treaty. It was provided, however, that the payments in the standard year should be increased with the increasing prosperity of Germany, the measure to be determined by an "Index of Prosperity" based upon comparative statistics of imports, exports, public revenues, population, consumption of sugar, etc. In this way it was at least possible that the sums ultimately payable annually would be greatly in excess of the 2½ milliards in the standard year. In the event of the economic circumstances of Germany's foreign trade being such that the transfer committee could not succeed in transferring the whole sum to the Allies, it was provided that there should be an accumulation in Germany up to a limit of 5 milliards, at which point, if necessary, the payment should be reduced.

The report set out the varying economic principles underlying the payment of reparations—principles which, up to that time, had not been generally recognized by the public or acted upon by politicians. In this connection it was laid down, for example, that:

> There has been a tendency in the past to confuse two distinct though related questions, *i.e.*, first the amount of revenue which Germany can raise available for reparation account, and, second, the amount which can be transferred to foreign countries. The funds raised and transferred to the Allies on reparation account cannot, in the long run, exceed the sums which the balance of payments makes it possible to transfer without currency and budget instability ensuing. But it is quite obvious that the amount of budget surplus which can be raised by taxation is not limited by the entirely distinct question of the condition of external transfer. We propose to distinguish sharply between the two problems, and first deal with the problem of the maximum budget of surplus and afterwards with the problem of payment to the Allies. In the past, the varying conclusions formed as to Germany's "capacity" have often depended upon which of these two methods has been chosen.

Schedule of Payments.—The provisions made for payment under the treaty were as follows:—

	Million gold marks
Budget; Moratorium Period:	
First year: from foreign loan and part interest (200 millions) on railway bonds;	
Total of	1,000
Second year: from interest on railway bonds (including 130 millions balance from first year) and interest on industrial debentures and budget contribution, including sale of railway shares;	
Total of	1,220
Transition Period:	
Third year: from interest on railway bonds and industrial debentures, from transport tax and from budget;	
Total of	1,200
Subject to contingent addition or reduction not exceeding 250 million gold marks.*	
Fourth year: from interest on railway bonds and industrial debentures, from transport tax and from budget;	
Total of	1,750
Subject to contingent addition or reduction not exceeding 250 million marks.*	
Standard Year:	
Fifth year: from interest on railway bonds and industrial debentures, from transport tax and from budget;	
Total of	2,500

*By subsequent agreement, Sept. 8, 1926, these two contingent payments were replaced by a *single* definite payment of 300 million gold marks during the third Annuity year.

The first year was to begin to run from the date when the Plan should have been accepted and made effective. These payments were to be absolutely inclusive of all the various expenses for military purposes that were being thrown upon Germany. They were also to include the value of deliveries in kind.

Securities for Payment.—The "securities" proposed were of three kinds: Taxes, railways and industrial debentures. As regards railways, the whole system was to be made over to a company and be no longer directly under the Reich. Railway bonds were to be set up. Eleven milliards of first mortgage railway bonds against a capital cost of 26 milliards to be created for reparations; these bonds to bear 5% interest and 1% sinking fund per annum; in view of reorganization, interest to be accepted as follows:—

1924–5	330 million gold marks.
1925–6	465 million gold marks.
1926–7	550 million gold marks.
1927–8	and thereafter: 660 million gold marks.

Behind the bonds there were to be created:—

2 milliards of preference shares to be reserved for sale to the public and

13 milliards of common stock.

Three-fourths of the proceeds of the preference shares was to be applied, as required, to the payment of debt and for capital expenditure of the railways. The remaining 500 millions of preference shares and all the common shares were to go to the German Government. They assigned the Transport Tax to the extent of the first 290 million gold marks for reparations. Industrial debentures were recommended: Five milliards of industrial debentures were to be provided for reparation; these bonds to bear 5% interest and 1% sinking fund, *i.e.*, 300 million gold marks per annum. Pending economic restoration, interest and sinking fund were to be accepted as follows:—

First year	Nothing.
Second year	125 million gold marks.
Third year	250 million gold marks.
Thereafter	300 million gold marks.

As further guarantee, they proposed to pledge certain revenues as collateral security, *i.e.*, the taxes on alcohol, tobacco, beer and sugar, and the customs, but only up to definite limits. An arrangement for control, simple in the ordinary course, but becoming drastic if circumstances demanded, was recommended. The new organization therefore required a trustee for railway and industrial bonds, three commissioners of (1) railways, (2) the bank, (3) controlled revenues, and they recommended an agent for reparation payments to co-ordinate the activities of the above and to preside over the transfer committee. The feature of the plan on which its whole inception depended was the raising of a foreign loan of 800 million gold marks, which had to serve the double purpose of a gold reserve and also financing the internal payment for the treaty in 1924–25. The report claimed to take the question of "what Germany can pay" out of the field of speculation and put it in the field of practical demonstration.

IV. ADOPTION OF THE REPORT

The reception of the report was immediately favourable, and it was finally adopted by the Governments concerned in the London Agreement on Aug. 30, 1924. Steps were immediately taken to put it into operation. So far as all formal acts and the setting-up of the machinery for the future working of the Plan were concerned, it may be said that everything went satisfactorily. The Reparation Commission officially stated: "Germany is faithfully fulfilling her reparation obligations as far as they are at present fixed." The actual test of the working of the full apparatus would come later, since the reparation payments to be

made by Germany in its early stages were comparatively negligible. That a new spirit was secured is beyond question. The first report of the Agent-General, Mr. S. Parker Gilbert, said:

It is too early to draw conclusions regarding the ultimate effects of the Plan. Broadly, it is an endeavour to stimulate confidence among peoples and to apply principles of reason and justice to a difficult, vital problem. The success of the Plan will be measured not alone in terms of payments effected. It will be determined also by the extent to which it helps to replace distrust and discord with confidence and conciliation. Its early operation has fulfilled expectations.

In his report during the third year he said:

The execution of the Plan is proceeding normally. Germany has made all the payments required of her during the first nine months of the third Annuity year, and deliveries and payments for the benefit of the creditor Powers have gone forward regularly and without interfering with the stability of the Exchange.

The pivot of the whole Plan for the first year was the German External Loan of 40 millions sterling or 800 million gold marks. In the words of the report, this was necessary to assure currency stability and financing essential deliveries in kind during the preliminary period of economic rehabilitation.

It enabled the Allies to receive something on account of reparations without, at the same time, any burden being placed upon the German budget. Negotiations were completed on Oct. 10, 1924, and on Oct. 13 the Reparation Commission constituted the service of the loan as a first charge on all the payments provided for under the Plan, and also on the collateral security of the controlled revenues and any other assets or revenues of Germany to which the powers of the Commission extended under the treaty. The transfer committee at its first meeting recognized the priority of the loan, and gave it an absolute right of remittance irrespective of the effects upon the exchange. This loan provided 800 million gold marks out of the total of 1,000 million gold marks, which constituted the first year's annuity, and the balance of 200 million gold marks came from the German Railway Company as interest on the bonds. Apart from this 200 millions, there was no drain whatever on the current resources of Germany for the first year.

Receipts.	Million gold marks.	Payments.	Million gold marks.
Cash withdrawn from proceeds of German External Loan, 1924	800·0	Payment to various Allied countries	789·0
Interest on railway bonds	200·0	Expenses of: Reparation Commission 5·6	
		Rhineland High Com. 0·4	
Exchange differences and Interest received	0·5	Military Com. of Control 7·7	
		Naval Com. of Control 0·07	22·8
		European Commission of the Danube	0·2
		Service of German External Loan	77·5
		On account of administration cost of office for reparation payments, and discount on railway payments in advance	3·9
		Cash in hand, Aug. 31, 1925	107·0
Total	1,000·5		1,000·5

The Working of the Plan.—The first complete year of the Dawes scheme is shown in the preceding table of receipts and payments.

The revised distribution of the third Annuity (year to Aug. 31, 1927) showing the shares of the respective Powers is given in the table in the next column.

The transfer committee had time to examine their problem before having to take any executive action on its chief difficulties. They were not called upon to decide delicate questions of exchange priority or pressure. Their first years were taken up in making arrangements for deliveries in kind and Reparation Recovery Acts. The latter in particular presented difficult questions which were described by the Agent General in his report. By forcing the German exporter to look to the German Government or Agent General for the deductions made by the British Government in respect of a total which had no relation to the Dawes Plan or to the sums transferable by the transfer committee, the British Government could virtually ride around the powers of the committee, "confronting them with an accomplished fact."

REVISED DISTRIBUTION OF THIRD ANNUITY—SHOWING SHARES OF THE RESPECTIVE POWERS

(In Millions of Gold Marks)

	Army costs.	Belgian war debt.	Restitution.	American mixed claims.	Reparations.	Total share.
France	114·2	26·8	7·2	..	596·5	744·7
British empire	35·7	23·0	·2	..	251·3	310·2
Italy	..	..	·1	..	96·6	96·7
Belgium	16·0	8·6	3·6	..	48·3	76·5
United States	55·0	..	..	24·7	..	79·7
Other countries	..	..	·6	..	80·7	81·3
Totals	221·0	58·4	11·7	24·7	1,073·4	1,389·2
	Service of German External Loan					91·6
	Costs of Inter-Allied Commissions					12·8
	Discount on Railway Interest					6·4
	Total of Third Annuity					1,500

In the report of the negotiations between the British Treasury and the Agent General, it was arranged for the German exporters as a whole to deliver to the Reichsbank monthly 30% of the sterling proceeds of their exports to Great Britain. Deposits are made at the Bank of England for credit to the Agent General's account. The transfer committee regains control and the system adjusts itself automatically to the British Government's share in the available annuity.

Towards the end of 1925 Germany passed from a stage of comparatively easy conditions into an industrial crisis which retarded the full development of her fiscal resources towards the position demanded by the final scale of the Plan, but her subsequent recovery was satisfactory from that point of view.

V. THE INDUSTRIAL ASPECTS OF REPARATIONS

It has been increasingly realized by the industrialists of the Allied nations that, just as the payment of reparations by Germany involved the necessity for her to maintain an export surplus, so the recipient countries may derive all they need of the goods involved by imports from Germany at the expense of the competing industries in the Allied countries, and that even if the surplus of German goods should go to neutral markets they may serve only to displace similar goods hitherto exported from the Allied countries. Hence the anomalous situation has arisen that reparation payments, speaking generally, have been ardently desired by the creditor Governments, but, speaking particularly, have been feared and resisted by the business men in the same countries.

Balance of Trade Problem.—The Committee on Economic Restoration of the International Chamber of Commerce in Nov. 1924 set up a sub-committee (Sir Josiah Stamp, Dr. Alberto Pirelli and Count André De Chalendar) to study the question of international transfers of reparation payment. One report signed by all three, and a supplementary one by the English member, were presented in May 1925, and adopted at the conference in Brussels in June 1925. The chief items and recommendations were:—

The solution of the "balance of trade" problem, in relation to the liabilities under the Dawes Plan, is to be found in the following order:—

1. By a considerable expansion of German exports to general world markets in the ordinary course and under those conditions normal to Germany without any special overhead organization or effort. This carries with itself the possibility of cash payments to the Allied Governments which is, of course, the ideal form for the latter of receiving reparation payments.

2. By arrangements between each Allied creditor country and Germany with a view of developing, in the widest possible manner compatible with national interests and the obligations of the transfer committee, deliveries in kind or services. This, though possibly in the long run not a major part of the total, is important. Serbia may want locomotives which she does not produce. Italy may want coal which she may not possess, France or Great Britain may want dyestuffs or potash. These are merely examples of a wide range of goods which Germany can probably deliver without difficulty.

3. By the operation of certain international co-ordination in enterprise and public works, by research and study and practical action, of which we have in this report given an illustration called "Assisted Schemes."

4. Where the three foregoing still leave a gap between the accumulation of reparation marks and their effective transmutation into external values, it may be possible to gain time and to defer the greater difficulties of forcing the Plan by two methods: (*a*) The sale of railway, industrial and eventually other German bonds on the international markets and (*b*) by making permanent investments in Germany which will belong to non-Allied or neutral holders. The method (*a*) above may play a very important part, either as redemption of capital debt or for the balance of the annuities. It must not be forgotten, however, that the extensive use of the plan throws a burden upon the future export surplus in addition to the fixed annuities. The system under (*b*) finds certain limitations under the Dawes Plan and in practice, but it may be *e.g.*, that an Argentine resident or a Brazilian will become the owner of property in Germany, or of shares in German companies, by means of the export of food or raw materials to Allied individuals. These sales, as also these loans, are not an immediate method of externalizing German wealth, but they, so to speak, stave off the day of difficulty and gain time. The difficulty of exporting £1,000 outright is transmuted into the smaller difficulty of transferring £50 or £60 interest thereon annually in perpetuity, a difficulty capable of retransmutation into capital at some distant date after the export surplus is no longer monopolized by reparation payments, by Germans buying in the investments held by foreigners in their own country.

While theoretically the "demand" of individuals in the Allied countries will be so increased by relief in taxation that it could, *in amount*, absorb a new supply of German goods, the demand will not fully coincide *in kind* with the goods which are offered. There may be, in consequence of this maladjustment, important reactions in price which will make the burden greater for Germany to discharge, make full transfers difficult, and induce unduly severe competition in certain markets. Moreover, vested industrial interests in both capital and labour in the Allied countries may be adversely affected, and, for various reasons, if the whole question is left to uncontrolled economic forces political difficulties will arise.

We have certain suggestions to make for co-ordinated and systematic international action which, while it may not affect a large sum in relation to the whole reparation annuity, may be of great importance in assisting a settlement of this *residual problem*. We conceive that there is everything to be gained by systematic study and the existence of a "safety valve" in the event of normal channels being inadequate for the purpose, to relieve the concentrated competition, and also to prevent the consequences of accumulation of reparation payments in Germany. Our proposal would tend to prevent existing channels of German trade being flooded by excessive supplies and by a prepared plan irrigate, without disaster and with ultimate profit to the world, a wider area than could otherwise be open.

The International Chamber decided to prosecute the idea of assisted schemes, but formed no organization to aid them. (J. S.)

VI Final Settlement.

The Dawes plan did not settle the total amount to be demanded from Germany in the form of Reparations, nor did it fix the duration of annuity payments. It was simply an arrangement which permitted the beginning of payments at once without waiting for a final solution of an extremely complicated problem. However, to postpone a final settlement for long was impossible. Under a decision taken at Geneva in 1928 a new commission of experts was appointed. Owen D. Young (*q.v.*), one of the two unofficial representatives from the United States was appointed chairman. Hjalmer Schacht (*q.v.*), head of the Reichsbank, was the chief German negotiator. The committee began its meetings at Paris in Feb., 1929, and brought them to a successful close early in June. Ratification of the Paris agreement by the parliaments of the various nations concerned still remained necessary.

The new annuities are less than under the Dawes Plan and payments are limited to a fixed number of years so that the highest amount for which Germany is to be held responsible is therefore fixed. The Dawes Plan annuities had reached £123,000,000 at which level they were to continue. The Young Plan calls for annuities averaging £101,000,000 for 37 years, and then for annuities averaging £85,700,000 until the 59th year when all payments are to cease. With the adoption of the new program the machinery of the Dawes Plan is to be discarded, and the Reparations Commission will cease to exist. To supersede the commission plans were worked out for a Bank of International Payments to handle all Reparations transactions. The bank will be governed by a board with representatives from each nation. (X.)

REPEAL, the abrogation, revocation or annulling of a law. (*See* ABROGATION and STATUTE.) The word is particularly used in English history of the movement led by Daniel O'Connell (*q.v.*) for the repeal of the act of Union between Great Britain and Ireland. (*See* IRELAND: *History.*)

REPERTORY THEATRE: *see* DRAMA.

REPIN, ILJA JEFIMOVICH (1844–1918), Russian painter, was born in 1844 at Tschuguev in the department of Charkov, the son of parents in straitened circumstances. He learned the rudiments of art under a painter of saints named Bunakov, for three years gaining his living at this humble craft. In 1863 he obtained a studentship at the Academy of Fine Arts of St. Petersburg (Leningrad), where he remained for six years, winning the gold medal and a travelling scholarship which enabled him to visit France and Italy. He returned to Russia after a short absence, and devoted himself exclusively to subjects having strong national characteristics. In 1894 he became professor of historical painting at the St. Petersburg academy. Repin's paintings are powerfully drawn, with not a little imagination and with strong dramatic force and characterization. He died at Knokkala on the Finnish frontier on July 17, 1918.

His chief pictures are "Procession in the Government of Kiev," "The Arrest," "Ivan the Terrible's murder of his Son," and, best known, "The Reply of the Cossacks to Sultan Mahmoud IV."

REPINGTON, CHARLES A'COURT (1858–1925), British military critic, was born on Jan. 29, 1858, and commissioned in the Rifle Brigade in 1878. After serving with distinction in the Afghan War, the Sudan and South Africa, he was appointed military attaché at Brussels and The Hague in 1900, being then a lieutenant-colonel. Two years later his military career ended abruptly through domestic causes, and he took up journalism, becoming military correspondent of *The Times* in 1904. In 1915, after staying with the British commander-in-chief in France, he came home to call attention to the shell shortage. In Jan. 1918 a divergence of views caused him to leave *The Times* for *The Morning Post*, and after the War he became military correspondent of *The Daily Telegraph*, a post which he held till his death at Hove, Sussex, on May 25, 1925.

His works include *Vestigia* (1919); *The First World War, 1914–18; Personal Experiences* (1920); *After the War; A Diary* (1922); *Policy and Arms* (1924).

REPLEVIN, a term in English law signifying the recovery by a person of goods unlawfully taken out of his possession by means of a special form of legal process; this falls into two divisions—(1) the "replevy," the steps which the owner takes to secure the physical possession of the goods, by giving security for prosecuting the action and for the return of the goods if the case goes against him, and (2) the "action of replevin" itself. The jurisdiction in the first case is in the county court (*q.v.*); in the second case the supreme court has also jurisdiction in certain circumstances. At common law, the ordinary action for the recovery of goods wrongfully taken would be one of detinue (*q.v.*); but no means of immediate recovery was possible till the action was tried, and until the Common Law Procedure Act 1854 the defendant

might exercise an option of paying damages instead of restoring the actual goods.

United States.—In the United States the action of replevin is almost entirely regulated by statute in each jurisdiction, and is materially different from the use and construction of the common law action of replevin in England. The action is laid upon a wrongful taking and a wrongful detaining or a wrongful detaining alone. It is a proceeding *in rem* to recover goods and chattels, *i.e.*, every kind of personal property to which the plaintiff has the right to present possession, and also, by statute, a proceeding *in personam*, to recover damages for either the detention or both the caption and detention, according to the wording of the statute. It is a possessory action, the gist of which is the right of possession in the plaintiff, but in nearly all cases the title is determined since the owner is entitled to possession, and possession by verdict where the title is in question awards title. It will not lie to recover real property or fixtures attached to the freehold, nor can it be maintained in any case in which the object sought is the determination of title to land. In some jurisdictions all damages growing out of the wrongful taking and detention may be assessed in the replevin action; in others, where the statute limits the recovery of damages to detention only, a separate subsequent action may be brought to recover compensatory and punitive damages sustained by a malicious wrongful taking (*Crockett* v. *Miller*, 112 Federal 729; *Petrie* v. *Wardman-Justice Motors*, Sup. Ct. D. C. No. 71,338). This is a rule peculiar to replevin, where so regulated by statute, and is at variance with the general rule of law requiring the adjudication in one cause of action of all claims and demands growing out of a single tort.

REPNIN, ANIKITA IVANOVICH, PRINCE (1668–1726), Russian general, and one of the collaborators of Peter the Great. He took part in all the principal engagements of the Great Northern War. Defeated by Charles XII. at Holowczyn, he was degraded to the ranks, but was pardoned as a reward for his valour at Lyesna and recovered all his lost dignities. At Poltava he commanded the centre. From the Ukraine he was transferred to the Baltic Provinces and was made the first governor-general of Riga after its capture in 1710. In 1724 he succeeded the temporarily disgraced favourite, Menshikov, as war minister. Catherine I. created him a field-marshal.

See A. Bauman, *Russian Statesmen of the Olden Time* (Rus.), vol. i. (St. Petersburg, 1877).

REPNIN, NIKOLAI VASILIEVICH, PRINCE (1734–1801), Russian statesman and general, grandson of the preceding, served during the Rhenish campaign of 1748 and subsequently studied in Germany. Peter III. sent him as ambassador in 1763 to Berlin. The same year Catherine transferred him to Warsaw, with instructions to form a Russian party in Poland from among the dissidents, who were to receive equal rights with the Catholics. Repnin convinced himself that the dissidents were too poor and insignificant to be of any real support to Russia, and that the whole agitation in their favour was factitious. At last, indeed, the dissidents themselves even petitioned the empress to leave them alone. The attempt had failed, and Repnin went to fight the Turks. At the head of an independent command in Moldavia and Walachia, he prevented a large Turkish army from crossing the Pruth (1770); distinguished himself at the actions of Larga and Kagula; and captured Izmail and Kilia. In 1771 he received the supreme command in Walachia and routed the Turks at Bucharest. A quarrel with the commander-in-chief, Rumyantsev, then induced him to send in his resignation, but in 1774 he participated in the capture of Silistria and in the negotiations which led to the peace of Kuchuk-Kainarji. In 1775–76 he was ambassador at the Porte. On the outbreak of the war of the Bavarian Succession he led 30,000 men to Breslau, and at the subsequent congress of Teschen, where he was Russian plenipotentiary, compelled Austria to make peace with Prussia. During the second Turkish war (1787–92) Repnin was, after Suvarov, the most successful of the Russian commanders. He defeated the Turks at Salcha, captured the whole camp of the *seraskier*, Hassan Pasha, shut him up in Izmail, and was preparing to reduce the place when he was forbidden to do so by Potemkin (1789). On the retirement of Potemkin (*q.v.*) in 1791, Repnin succeeded him as commander-in-chief, and immediately routed the grand vizier at Machin, a victory which compelled the Turks to accept the truce of Galatz (July 31, 1791). In 1794 he was made governor-general of the newly acquired Lithuanian provinces. The emperor Paul raised him to the rank of field-marshal (1796), and, in 1798, sent him on a diplomatic mission to Berlin and Vienna in order to detach Prussia from France and unite both Austria and Prussia against the Jacobins. He was unsuccessful, and on his return was dismissed from the service.

See A. Kraushar, *Prince Repnin in Poland, 1764–8* (Pol.) (Warsaw, 1900); "Correspondence with Frederick the Great and others" (Rus. and Fr.), in *Russky Arkhiv* (1865, 1869, 1874, Petersburg); M. Longinov, *True Anecdotes of Prince Repnin* (Rus.) (St. Petersburg, 1865).

REPORTING, the business of reproducing, mainly for newspapers, but also for such publications as the *Parliamentary* or *Law Reports*, the words of speeches, or of describing the events in contemporary history by means of the notes made by persons known generally as reporters. There was no systematic reporting until the beginning of the 19th century, though there was parliamentary reporting of a kind almost from the time when parliaments began, just as law reporting (which goes back to 1292) began in the form of notes taken by lawyers of discussions in court. The first attempts at parliamentary reporting, in the sense of seeking to make known to the public what was done and said in parliament, were made by the *Gentleman's Magazine* in 1736. Access to the houses of parliament was obtained by Edward Cave (*q.v.*), the publisher of this magazine, and some of his friends, and they took surreptitiously what notes they could. These were subsequently put into shape for publication by another hand. Such reporting was a violation of the standing order of the House, passed in 1728, declaring the publication of any of its proceedings to be a breach of privilege, and on the attention of the House being called in 1738 to the reports in the *Gentleman's Magazine* it threatened to proceed with the utmost severity against the offenders. Thereupon Cave published his reports as "Debates in the Senate of Lilliput," and instead of giving the first and last letters of each speaker's name, employed such barbaric terms as "Wingul Pulnub" for William Pulteney. Dr. Johnson composed the speeches for the *Gentleman's Magazine* from 1740 to 1743, the names of the speakers being given in full. Though he said he took care not to let the "Whig dogs" get the best of it, he really dealt out argument and eloquence with equal hand to both political parties.

In the latter half of the century the newspapers began to report parliamentary debates more fully, with the result that, in 1771, several printers, including those of the *Morning Chronicle* and the *London Evening Post*, were ordered into custody for publishing debates of the House of Commons. A long and bitter struggle between the House and the public ensued. John Wilkes took part in it. The lord mayor of London and an alderman were sent to the Tower for refusing to recognize the Speaker's warrant for the arrest of certain printers of parliamentary reports. But the House of Commons was beaten. In 1772 the newspapers published the reports as usual; and their right to do so has never since been really questioned. Early in the 19th century, greater freedom of access to both Houses was given to newspaper reporters. By the middle of the century special galleries for their accommodation were provided in the legislative chambers of the new palace of Westminster erected in place of the old which was burned down in 1834. The press gallery of the House of Lords was first used in 1847, and the press gallery of the House of Commons in 1852. At this time the London newspapers had a monopoly of parliamentary reporting. Only their representatives were admitted to the galleries, which secured them this virtual monopoly.

The Times established a supremacy for the best parliamentary report, which has never been shaken. The other London papers, however, gave less and less attention to the debates while at the same time the public throughout the country wanted to know more fully what their representatives were saying in parliament. Gradually the leading provincial newspapers adopted the

practice of employing reporters in the service of the London journals to report debates on subjects of special interest in localities; and these reports, forwarded by train or by post, were printed in full, but of course a day late. The London papers paid little attention to debates of local interest, and thus the provincial papers had parliamentary reporting which was not to be found elsewhere. Bit by bit this feature was developed. It was greatly accelerated by the arrangement of placing telegraphic wires from London at the disposal of provincial newspapers—of course on payment of a large subscription—from six o'clock at night till three o'clock in the morning. This was the beginning of the "special wire" which now plays so important a part in the production of almost all newspapers. The arrangement was first made by the *Scotsman* and by other newspapers in Scotland in the 'sixties. The special wires were used to their utmost capacity to convey reports of the speeches of leading statesmen and politicians; and, instead of bare summaries of what had been done, the newspapers contained pretty full reports. When the telegraphs were taken over by the State in 1870 the facilities for reporting were increased in every direction. News agencies undertook to supply the provincial papers. These agencies were admitted to the reporters' galleries in the houses of parliament, but the reports which any agency supplied were identical; that is to say, all the newspapers taking a particular class of report had exactly the same material supplied to them—the reporter producing the number of copies required by means of manifold copying paper. Accordingly attempts were made by leading provincial newspapers to get separate reports by engaging the services of some of the reporters employed by the London papers. The "gallery" continued to be shut to all save the London papers and the news agencies. The *Scotsman* sought in vain to break through this exclusiveness. The line, it was said, must be drawn somewhere, and the proper place to draw it was at the London press. But in 1880 a select committee of the House of Commons was appointed to consider the question. It took evidence, and it reported in favour of the extension of the gallery and of the admission of provincial papers. The press gallery of the House of Commons was accordingly enlarged and representatives of the leading provincial newspapers were admitted at the opening of the session of 1881.

What is commonly called "descriptive reporting" has in some cases nearly shouldered the reporting of speeches out of newspapers. The special correspondent or the war correspondent is a "descriptive reporter." The "interviewer" came into great prominence during the 'eighties and 'nineties. The variety of work open to reporting causes considerable difference, of course, in the professional status of the journalists who do such work. This subject generally is discussed in the article NEWSPAPERS, but one instance of the recognition of the modern reporter's responsibility is worth special mention. In the year 1900, in the English case of *Walter* v. *Lane* (*see* COPYRIGHT), it was decided, on the final appeal to the House of Lords, that the reporter of a speech, printed verbatim in a newspaper, was under the Copyright Act of 1842 to be considered the "author." Absurd as it might seem to call the reporter the author of another man's speech, the decision gave effect to the fact that it is his labour and skill which bring into existence the "copy" to which alone can right of property attach. Strictly speaking, he is the author of the *report* of the speech; but for literary purposes the report *is* the speech. It must, however, be borne in mind that there may be more than one verbatim report, and therefore more than one "author." *See* also NEWSPAPERS; SHORTHAND; PRESS LAWS; TELEGRAPH.

(X.; M. MACD.)

UNITED STATES

The system of newspaper reporting developed in America responds to a code of ethics which, although unwritten and without centralized machinery to enforce it, is, nevertheless, a potent influence throughout journalism. These governing rules naturally arise from newspaper experience and legends, and increasingly take concrete form, somewhat by reason of the fact that 80 professional schools of journalism have in recent years sprung up in the United States, most of them being departments of established colleges or universities. It may in general be said that the reporter, whether instructed as a "cub" in the newspaper office or as a student in a professional school, learns that the newspaper, while privately owned and published for profit, is in fact quasi-public in that it possesses a constitutional guarantee of freedom and owes to society commensurate responsibility to ventilate news which concerns public welfare. News is variously described, but it is generally held to be written record of any event of public interest, reported either on evidential authority of the writer or authenticated by a credited witness. It is assumed that the newspaper may freely publish any news which may be discussed in decent society, which is true, which is not forbidden by law and which serves the public interest. This, of course, means that the reporter must use his powers to ascertain the truth and state it fairly in his report, guard against injustice or harm to individuals or institutions written about, avoid promotion of any private interest, keep confidences that are imparted to him, refuse to serve partisanship by exaggerating the favourable and suppressing the unfavourable factors in news columns and in every way write as considerately and fairly of strangers or antagonists as of protagonists and acquaintances. The reporter is called upon to keep faith both with those concerning whom he writes and those who buy and read his accounts. In modern practice the publication of the news writers' opinion is prohibited, the newspaper reserving the editorial page for the purpose of expressing views, as distinguished from news. The rule is to avoid trespass upon private rights or feelings, except when such course is dictated by certain knowledge that the ends of justice or the welfare of the social order demand such action. A newspaper may not publish advertising in its news columns, without designation. The reporter and his newspaper are called upon by custom to make proper, full and free correction of errors previously made in print. These, sketchily, are the canons of American journalism. The nearest approach to a written code which has general acceptance is that of the American Society of Newspaper Editors, composed of the editors of many of the country's leading newspapers.

Organization.—The organization of the average American newspaper's editorial department is as follows: editor-in-chief, directing policy; managing editor, in control of the writing staff and the composing room; chief editorial writer, conducting the editorial page; city editor, controlling the local staff of reporters, photographers and, perhaps, artists; head of copy-desk, directing the actual preparation of the news as it will appear in print; rewriters, graduate reporters held in the office to write the news that reporters transmit by telephone or rewrite their reports to meet the exigencies of the edition; foreman of the composing-room, responsible to the managing editor or editor-in-chief for the setting of type and delivery of forms of type to the stereotype and press rooms; telegraph editor, responsible for the editing of news which comes by wire, product of the press associations and services and the newspaper's special out-of-town correspondents. Such departments as sports, financial, commodity markets, woman's page, religion, humour and the Sunday edition, if any, are conducted by editors appointed by the managing editor or the editor-in-chief. The three great sources of information are (1) material written by the local staff; (2) news coming by wire; (3) feature material delivered by syndicates, of which there are more than 200 in the United States competing for newspaper patronage. In New York and Chicago local newspapers have established co-operative news organizations through which the routine reports of courts, police headquarters, city hall and such public offices are supplied by a single reporter for all newspapers, although all important events are covered by staff reporters assigned by city editors.

The rank and file of reporters are young men, or occasionally women, who have received public school and college education, perhaps 15 or 20% of them having matriculated in journalism. Those who are talented as fact-finders and as writers usually receive quick promotion, such recognition giving them higher salaries than is usually paid to young people in the professions or the fields of finance, commerce or education. Reporting, in the matter of compensation, ranks with the arts and while true genius

reaps a quick and ample reward mediocre talent is only fairly paid and the mere drudgery of reporting is as poorly paid as clerkships or common labour. (M. E. P.)

REPOUSSÉ (Fr. "driven back"), the art of raising designs upon metal by hammering from the back, while the "ground" is left relatively untouched. The term is often loosely used, being applied indifferently to "embossing." Embossing is also called *repoussé sur coquille* and *estampage*, but the latter consists of embossing by mechanical means and is therefore not to be considered as an art process. Moreover, it reverses the method of repoussé, the work being done from the front, and by driving down the ground leaving the design in relief.

Repoussé—a term of relatively recent adoption, employed to differentiate the process from embossing—has been known from remote antiquity. Nothing has ever excelled, and little has ever approached, the perfection of the bronzes of Siris (4th century B.C., in the British Museum), of which the armour-plate—especially the shoulder-pieces—presents heroic figure-groups beaten up from behind with punches from the flat plate until the heads and other portions are wholly detached—that is to say, in high relief from the ground of which they form a part. Yet the metal, almost as thin as paper, is practically of constant thickness, and nowhere is there any sign of puncture.

The art was not only Greek and Graeco-Roman in its early practice; it was pursued also by the Assyrians, the Phoenicians, and other oriental peoples, as well as in Cyprus and elsewhere, and was carried forward, almost without a break, although with much depreciation of style and execution, into mediaeval times. In the 11th century the emperor Henry II. presented as a thank-offering to the Basle cathedral the altar-piece, in the Byzantine style, decorated with fine repoussé panels of gold (representing Jesus Christ with two angels and two saints), which is now in the Cluny Museum in Paris. Up to this time, also, repoussé instead of casting in metal was practised for large work, and Limoges became a centre for the manufacture and exportation of sepulchral figures in repoussé bronze. These were affixed to wooden cores. By the time of Benvenuto Cellini the art was confined almost entirely to goldsmiths and silversmiths (who, except Cellini himself, rarely cast their work); and to them the sculptors and artists of to-day are still content to relegate it.

The elementary principle of the method, after the due preparation and annealing of the plate, was to trace on the back of it the design to be beaten up, and to place it face downwards upon a stiff yet not entirely unresisting ground (in the primitive stage of development this was wood), and then with hammers and punches to beat up the design into relief. According to Cellini, his master Caradosso da Milano would beat up his plate on a metal casting obtained from a pattern he had previously modelled in wax; but he is not sufficiently explicit to enable us to judge whether this casting was a hollow mould, which would result in true repoussé, or in the round, which is tantamount to *repoussé sur coquille*, or embossing.

Nowadays the plate is laid upon and affixed to a "pitchblock," a resinous ground docile to heat, usually composed of pitch mixed with pounded fire-brick, or, for coarser work such as brass, with white sand, with a little tallow and resin. This compound, while being sufficiently hard, is elastic, solid, adhesive and easy to apply and remove. Gold and silver are not only the densest and most workable but the most ductile metals, admitting of great expansion without cracking if properly annealed. The tools include hammers, punches (in numerous shapes for tracing, raising, grounding, chasing and texturing the surfaces), together with a special anvil called in French a *recingle* or *ressing*, in English "snarl." The *recingle*, or small anvil with projecting upturned point, was known in the 16th century. This point is introduced into the hollow of the vase or other vessel such as punch and hammer cannot freely enter, which it is desired to ornament with reliefs. A blow of a hammer on that part of the anvil where the prolongation first projects from it, produces, by the return spring, a corresponding blow at the point which the operator desires to apply within the vase. The same effect is produced by the modern "snarl" or "snarling iron"—a bar of steel, with an inch or two of the smaller end upturned and ending in a knob—held firmly in a tightly screwed-up vice, whereby the blow is similarly repeated or echoed by vibration. The repoussé work, when complete, is afterwards finished at the front and chased up. (*See* also EMBOSSING; BRONZE; SILVERSMITHS AND GOLDSMITHS WORK.)

(M. H. S.)

REPRESENTATION, a term used in various senses in different connections, but particularly in a political meaning, which has developed out of the others. The word "represent" comes from Lat. *re-praesentare*, to "make present again," or "bring back into presence," and its history in English may be traced fairly well by the citations given in the *New English Dictionary* of its earliest uses in literature in senses which are still common. Thus we find the verb meaning (1380) simply to "bring into presence," and Barbour uses it (1375) in the sense of bringing clearly before the mind, whence the common sense of "explain," "exhibit," "portray." In 1513 it is used as synonymous with "describe," or "allege to be." In 1460 we find it employed for the performance of a play or a part in a play, whence comes the sense of symbolizing, standing in the place of some one, or corresponding to something; and in 1655 for acting as authorized agent or deputy of some one. This is a notable point in the development of the word. In Cromwell's speech to the parliament, Jan. 22, 1655, he says: "I have been careful of your safety, and the safety of those you represented." This strictly political use of the verb developed, it will be seen, comparatively late.

The noun "representation" passed through similar stages. In 1624 it comes to mean "substitution of one thing or person for another," "substituted presence" as opposed to "actual presence," or "the fact of standing for, or in place of, some other thing or person," especially with a right or authority to act on their account. Its application to a political assembly then becomes natural, but for some time it is not so found in literature, the sense remaining rather formal. In Scots law (1693) it obtains the technical meaning of the assumption by an heir of his predecessor's rights and obligations.

The term "representative," now specially applied to an elected member of a national or other assembly, deriving his authority from the constituency which returns him, appears to have been first used to denote not the member but the assembly itself. In the Act abolishing the office of king, after Charles I.'s execution, 1649, s. iv. runs: "And whereas by the abolition of the kingly office provided for in this Act, a most happy way is made for this nation (if God see it good) to return to its just and ancient right of being governed by its own Representatives or national meetings in council, from time to time chosen and entrusted for that purpose by the people, it is therefore resolved and declared by the Commons assembled in Parliament," etc., "and that they will carefully provide for the certain choosing, meeting and sitting of the next and future Representatives," etc. But the application of the term to the persons who sat in parliament was at all events very soon made, for in 1651 Isaac Penington the younger published a pamphlet entitled "The fundamental right, safety and liberty of the People; which is radically in themselves, derivatively in the Parliament, their substitutes or representatives."

It is worth while to dwell on the historical evolution of the various meanings of "represent," "representation" and "representative," because it is at least curious that it was not till the 17th century that the modern political or parliamentary sense became attached to them; and it is well to remember that though the idea of political representation is older and thus afterwards is expressed by the later meaning of the word, the actual use of "representation" in such a sense is as modern as that. In Burke's speeches of 1769 and 1774–75, relating to taxation, we find the word in this sense already in common use, but the familiar modern doctrine of "no taxation without representation," however far back the idea may be traced, is not to be found in Burke in those very words. The "originator of that immortal dogma of our (*i.e.*, American) national greatness" was, according to the American writer M. C. Tyler (*Amer. Lit.* i. 154), the politician and philanthropist Daniel Gookin (1612–87), an Irish settler in Virginia, who, moving to Boston and becoming speaker of the Massa-

chusetts legislature, became prominent in standing up for popular rights in the agitation which resulted in the withdrawal of the colonial charter (1686). But it was the vogue of the "dogma" in America, not its phrase, that he seems to have originated; and while the precise form of the phrase does not appear to be attributable to any single author, the principle itself was asserted in England long before the word "representation," in a political sense, was current. In English constitutional history the principle was substantially established in 1297 by the declaration *De Tallagio non concedendo,* confirmed by the Petition of Right in 1628.

Political Representation.—The growth of the parliamentary system in England is traced in the article PARLIAMENT. Under Henry III., in 1254, we have the writ requiring the sheriff of each county to "cause to come before the King's Council two good and discreet Knights of the Shire, whom the men of the county shall have chosen for this purpose in the stead of all and of each of them, to consider along with knights of other shires what aid they will grant the king." But the definite establishment of the principle of political representation, in a shape from which the later English system of representation lineally descended, may be traced rather to the year 1295, in Edward I.'s famous writ of summons to parliament, of which the following is the important part. In the volume of *Select Documents of English Constitutional History* (1901), selected by G. B. Adams and H. M. Stephens, whose version from the Latin we quote, the section is headed (antedating the use of the vital word), "Summons of representatives of the counties and boroughs":—

> The king to the sheriff of Northamptonshire. Since we intend to have a consultation and meeting with the earls, barons and other principal men of our kingdom with regard to providing remedies against the dangers which are in these days threatening the same kingdom; and on that account have commanded them to be with us on the Lord's Day next after the feast of St. Martin in the approaching winter, at Westminster, to consider, ordain and do as may be necessary for the avoidance of these dangers: we strictly require you to cause two knights from the aforesaid county, two citizens from each city in the same county and two burgesses from each borough, of those who are especially discreet and capable of labouring, to be elected without delay, and to cause them to come to us at the aforesaid time and place. Moreover, the said knights are to have full and sufficient power for themselves and for the community of the aforesaid county, and the said citizens and burgesses for themselves and the communities of the aforesaid cities and boroughs separately, then and there, for doing what shall then be ordained according to the Common Council in the premises, so that the aforesaid business shall not remain unfinished in any way for defect of this power. And you shall have there the names of the knights, citizens and burgesses, and this writ.

The words "Elegi facias," instead of "venire facias" (which were retained in 1275; *see* PARLIAMENT), still appear to make the parliament of 1295 the model, rather than that of 1275, though in other respects the latter appears now to have established the summoning of county and borough representatives.

In this summoning by the king of the two knights and two burgesses with full and sufficient power *for themselves and for the community,* we find therefore the origin of political representation of the commons, as opposed to the actual presence and personal attendance of the peers. But it must always be remembered that the idea of "majority rule," *i.e.,* that an assembly of persons could bind a minority of its members, is a conception of slow growth. The "Common Council" of Magna Carta was far from holding that it had any right to bind any dissentient members. As McKechnie, in his "Commentary on Magna Carta" (1914), aptly observes, " 'No new exactions without the consent of the *individual* taxed' was nearer the ideals of 1215 than 'no taxation without the consent of parliament'." Indeed in 1221, a member, the bishop of Winchester, of a council, summoned to consent to a scutage tax, refused to pay, after the council had made the grant, on the ground that he dissented and the Exchequer upheld his plea. In the case of the Commons, where each individual "represented" other persons besides himself, such an attitude was, of course, absent—the very fact of their *election* discountenanced it. But, as Gierke says (*Political Theories of the Middle Age,* pp. 64 and 166), the idea of old Germanic law was that, even in a more or less "representative" assembly, "unanimity is requisite," although "a minority ought to, and can be, compelled to give way." The idea of representation and with it, majority rule, makes its way into the political sphere through the church councils who adopted it from the law of corporation (Gierke, p. 64). But even in the church the canonists held that minorities had certain irrefragable rights and that matters of faith could not be decided by mere majorities.

The Theory of Representation.—The idea of "representation" as opposed to "presence in person" was applied to the English parliament, so as to give the commons a proper voice in it as well as the lords. It is unnecessary here to trace further the gradual increase in power of the House of Commons till it became the predominant partner in the English bicameral constitution. (*See* PARLIAMENT.) But from the point of view of historical theory it is important to note that its representative character does not essentially depend upon the particular method (election *by vote*) by which its members have for so long been chosen. It is a common error to regard the House of Commons as having a national authority higher than that of the House of Lords merely on the ground that it is composed of elected members, and to stigmatize the House of Lords as "unrepresentative" because it is not elected. But in strictness the question of election, as such, has nothing to do with the matter. The proper distinction (ignoring for the moment the later inclusion in the House of Lords of a certain representative element—strictly so regarded—in the Scotch and Irish peers) is that the House of Lords, as still constituted in 1910, remained a *presentative* chamber, while the House of Commons was essentially a *representative* one; in the former the members, summoned personally as individuals, were entitled to speak in the great council of the nation, while in the latter the members were returned as the mouthpieces of whole *communitates,* to whom, in the person of the sheriffs, the summons had been directed to send persons to speak for them.

The preponderant authority of the House of Commons is due not to its members being elected—that is only one way of settling who the mouthpieces of the commons shall be—but to the progress of popular government. The two British houses have historically existed as assemblies of the separate estates of the realm—the House of Lords of the two estates of lords spiritual and temporal, and the House of Commons of the commons. The third estate has so increased in power as to become predominant in the country; but the authority of its own assembly simply depends on the powers of those it represents. If the balance of political power had not been shifted in the country itself, the authority and competence of the peers, speaking for themselves in a primary assembly, would in theory actually appear higher, so far as their order is concerned, than that of members of the House of Commons, who can only "represent" the popular constituencies. Moreover, the fact that most members of the House of Commons are elected by a party vote is apt to make them very often even less authoritative spokesmen of their constituencies—the *communitates*—than if they were selected by some method which would indicate that they had the full confidence of the whole body they "represent."

It is notorious that many members of a modern House of Commons, or of any other "representative" assembly, have only been elected by the votes of a minority of their constituency, or (where there have been more than two candidates) a minority even of those who voted; and there always comes a time when it is certain that if a representative has to come again before the electorate for their votes he will be defeated; he, in fact, no longer reflects their views, while he still sits and legislates. The real desires of the commons in a certain British constituency may even be more faithfully, even if only accidentally, reflected by a local peer whose only right to speak in parliament is technically presentative. In his *Vindication of the British Constitution* (1835), Disraeli, writing of the Reform Bill of 1832, observed that "in the effort to get rid of representation without election, it will be well if eventually we do not discover that we have only obtained election without representation." A truer word was never spoken. A man may be representative, practically *consensu omnium,* although no vote, resulting from a division of opinion, has been

taken for the purpose of selecting him. The vote is merely a method of selection when there is a definite division of opinion involving an uncertainty; and even in the modern House of Commons many members are returned "unopposed," no actual voting taking place. A well-recognized representative character (as regards the functions involved) attaches, for instance, in British public life to other persons in whose selection the method of popular voting has had no place; such as the king himself, the Cabinet (in relation to the political party in power), or the bishops (as regards the Church of England).

Expression of the "Will of the People."—It remains nevertheless the fact that, in politics, "representative" government means not so much government by men really representative of the nation as government in the name of the whole body of citizens (and predominantly the estate of the commons) through a chamber or chambers composed of elected deputies. The object in view is the expression of the "will of the people"—the people, that is, who are sovereign. Clearly the only pure case of such government can be in a republic, where there is only one "estate," the free citizens. The home and historical type of representative government, the United Kingdom, is strictly no such case, since the monarchy and the House of Lords exist and work on lines constitutionally independent of any direct contact with the electorate. British practice, however, is of vital importance for the theory of representative institutions, and it is worth while to point out that the "will of the people" may even so be effectively expressed—some people may think even more effectively expressed than in a pure republic. The king and the House of Lords are just as much part of "the people," in the widest sense, as "the commons" are; they are an integral part of the nation. Until 1911 they remained entitled and expected to use their historic method of playing a part in the government of the State. They assist to constitute "the people" in the wider sense, and in the narrower sense "the people" (*i.e.*, the commons) know it and rely on it.

Under the British constitution the commons have habitually relied on the monarchy and the House of Lords to play their part in the State, and on many occasions it has been proved, by various methods by which it is open to the commons themselves to show their real feeling, that action on the part of the monarch (*e.g.*, in foreign affairs) or the House of Lords (in rejecting or modifying bills sent up by the House of Commons), in which a popular vote has played no initiating or controlling part, is welcomed and ratified, by consent of a large majority, on the part of the nation at large. But the Parliament Act of 1911 has changed all that by reducing the function of the House of Lords to a purely suspensory veto on legislation, a veto the exercise of which may be automatically terminated in three sessions by the will of the Commons without any appeal to the electorate. It is notorious, in the case of the House of Lords, that elected members of the House of Commons, tied by purely party allegiance and pledges, have constantly voted for a measure they did not want to see passed, relying on the House of Lords to throw it out.

Ultimately, no doubt, the reconciliation of this "presentative" element in the British form of constitution with the growth of democracy and the predominance of the "representative" system depends purely on the waiving of historical theory both by king and peers, and its adaptation to the fact of popular government through the recognition that their action rests for its efficient authority upon conformity with the "will of the people." Thus it became an established maxim in England that while it was the proper function of the House of Lords to reject a measure which in their opinion is not in accordance with the wishes of the nation, they could not repeat such a rejection after a general election had shown that its authors in the House of Commons were supported by the country. The experience of politics from 1832 to 1910 gave abundant justification to the House of Lords for supposing that in such cases they were interpreting the desire of the country better than the House of Commons; the case of the Irish Home Rule bill of 1893 is, of course, the classical example. The violent attacks made on the House of Lords by the Liberal Party, on occasions when that party has had a majority in the commons and has had its measures rejected or distastefully amended, have always been open to the criticism that if the majority in the House of Commons were really supported by the electorate in the country they had the remedy in their own hands.

The Suffrage.—The immense extension of the "representative principle" in government, by means of popular election, and its adaptation to municipal as well as national councils, has in recent times resulted in attracting much attention to the problem of making such elected bodies more accurately representative of public opinion than they frequently are. There are three distinct problems involved—(1) that of making the number of enfranchised citizens correspond to a real embodiment of the nation; (2) that of getting candidates to stand for the office of representative who are competent and incorruptible exponents of the national will, and (3) that of adopting a system of voting which shall result in the elected representatives forming an assembly which shall adequately reflect the balance of opinion in the electorate.

There are various interesting questions as to the principles which should govern the extension of the suffrage and its limitations, to which a brief reference may here be made. It is noteworthy that John Stuart Mill, the philosophical radical whose work on *Representative Government* (first published in 1861) is a classic on the subject, and who regarded the representative system as the highest ideal of polity, made a good many reservations which have been ignored by those who frequently quote him. Mill's ideal was by no means that popular government should involve a mere counting of heads, or absolute equality of value among the citizens. While holding that "no arrangement of the suffrage can be permanently satisfactory in which any person or class is peremptorily excluded, or in which the electoral privilege is not open to all persons of full age who desire to obtain it," he insisted on "certain exclusions." Thus he demanded that universal education should precede universal enfranchisement, and laid it down that if education to the required amount had not become universally accessible and thus a hardship arose, this was "a hardship that had to be borne." He would not grant the suffrage to any one who could not read, write and perform a sum in the rule of three. Further, he insisted on the electors being taxpayers, and emphasized the view that, as a condition annexed to representation, such taxation should descend to the poorest class "in a visible shape," by which he explained that he did *not* mean "indirect taxes," a "mode of defraying a share of the public expenses which is hardly felt." He advocated for this purpose "a direct tax, in the simple form of a capitation" on every grown person. But even more than this, he was in favour of a form of plural voting, so that the intellectual classes of the community should have more proportionate weight than the numerically larger working-classes: "though every one ought to have a voice, that every one should have an equal voice is a totally different proposition."

Modern democracy may ignore Mill's emphatic plea for plural voting, as it ignores his equally strong arguments against the ballot—his contention being that secret voting violated the spirit of the suffrage, according to which the voter was a trustee for the public, whose acts should be publicly known—but Mill's discussion of the whole subject proceeds on high grounds which are still worth careful consideration. Where a representative system, as such, is extolled as the ideal polity, the reservations made by Mill, a liberal thinker who cannot be dismissed as a prejudiced reactionary, should be remembered. Mill postulated, in any event, a state of society which was worthy of such a system, no less than the necessary checks and balances which should make it correspond to the real conditions of rational government. "Representative institutions," he pointed out, "are of little value, and may be a mere instrument of tyranny or intrigue, when the generality of electors are not sufficiently interested in their own government to give their vote, or, if they vote at all, do not bestow their suffrages on public grounds, but sell them for money, or vote at the beck of some one who has control over them, or whom for private reasons they desire to propitiate. Popular election, as thus practised, instead of a security against misgovernment, is but an additional wheel in its machinery."

As regards the important question of the selection of candi-

dates (which depends partly on their willingness to stand, and partly on the means available for discovering suitable persons), modern practice is entirely dominated by the organization of political parties and the requirements of party allegiance. Though much has been said as to the desirability or not of paying members for their services (*see* PAYMENT OF MEMBERS), this is certainly overshadowed by the question of the availability of really capable men at all to the number required, for all candidates become "professional" politicians, whether paid or not. The ideal of having a "representative man" in the broader sense as a "representative" in the narrower is only very roughly attained where the conditions of public life make a capacity for electioneering a necessity. To a large extent the political candidate depends purely upon the support of a party organization. His choice rests with party wire-pullers, and the average individual elector is confronted with the task of voting for some one of whom he may personally know very little, except that, if returned, the candidate will in parliament vote for measures embodying certain general principles as indicated in some vague party programme.

Systems of Voting.—The more important point to be considered here is the third. When a representative assembly is to be elected by a direct popular vote, it is obviously necessary (*a*) that either there should be some system by which the whole body as a unit should elect all the members *en bloc*, or, as this usually appears impracticable, that the mass of electors should be divided within defined areas, or "constituencies"; and (*b*) that in the latter case voting shall take place for the purpose of electing one or more representatives of each such area according to some method by which due effect shall be given to the preferences of the electors. In theory there can be no perfectly fair arrangement as between constituency and constituency, where a single representative is to be returned, except on the terms that they are exactly equal in the number of electors; each elector's voice would then count equally with that of any other in the nation (or *mutatis mutandis* in the municipality, etc.). But in practice it is difficult to the point of impossibility to attempt more than an arbitrary distribution of electoral areas, more or less approximating to equality; and recourse is had to the formation of constituencies out of geographical districts taken as units for historical or practical reasons, and necessarily fluctuating from time to time in population or influence. It may become necessary periodically to revise these areas by what in England are called Redistribution Acts, but it has to be admitted that any perfect system of representation is always stultified by the necessary inequalities involved; and what is known as "gerrymandering" is sometimes the result, when a party in power so recasts the electoral districts as to give more opportunity for its own candidates to be returned than for those of its opponents. This flaw is particularly noticeable when the arrangement for the method of voting is that which allots only one member or representative to each district (*scrutin d' arrondissement*).

The essential vice of this single-member system, which prevails in Great Britain and the United States, is the lack of correspondence between the proportions in which the elected members of each party stand to one another and the proportions in which the numbers of the electors who returned them similarly stand; and it may well be that the minority party in the country obtains a majority of representatives in the assembly, or at any rate that a substantial minority obtains an absurdly small representation. "As a result of the district system," writes Prof. J. R. Commons of Wisconsin (*Proportional Representation*, 1907), "the national House of Representatives (in America) is scarcely a representative body. In the Fifty-first Congress, a majority of representatives were elected by a minority of the voters"; the figures being 5,348,379 Republican votes with 164 elected, and 5,502,581 Democratic votes with 161 elected. In the case of the Fifty-second Congress, the Democrats, with 50·6% of the votes, returned 71·1% of the representatives; the Republicans, with 42·9% of the votes, returning 26·5% of the representatives. Lord Avebury (*Proportional Representation*, 1890; new ed. 1906) has given various similar experiences in England; thus, at the general election of 1886, the Liberals, with 1,333,400 votes, only obtained 176 seats, while the Unionists, with 1,423,500, obtained 283 (not counting 99 unopposed returns on the Liberal side, and 111 on the Unionist). So with subsequent elections. In 1906, the Unionist vote, though 44% of the total cast, returned only 28% of the members, and the Liberal majority, which in strict proportion would have been 68, actually was 256.

The definite emergence of a third party system in England, with the rise of the Labour Party, has accentuated such paradoxes. It frequently happens that with three candidates, Conservative, Liberal and Labour, the candidate who heads the poll is returned with a minority of the total number of votes cast. At the general election of 1924, over 16 million votes were recorded, but of the 615 members returned the Liberal party only won 39 seats although nearly three million electors voted in its favour. On a purely numerical basis of votes it was entitled to at least 100 representatives. Together, the two opposition parties, Liberal and Labour, actually polled some 250,000 more votes than the Conservative Party, but only secured 189 seats against 413 seats won by the Conservatives.

The establishment of mere party majority rule, which is characteristic of a representative system, is a necessity, no doubt, in popular government; but the way in which a substantial minority of voters may only obtain a contemptible minority of members, and may in practice be tyrannized over in consequence, somewhat detracts from its blessings, and leads to extreme party measures. The division of the whole electoral body into constituencies is, after all, only a device for getting over the difficulty of the electors voting *en bloc*, and it does not seem to justify the conversion of a real majority in the country into a minority as represented in parliament, nor the complete exclusion of a substantial number of the electorate from parliamentary representation—so far as their views are concerned—at all. Yet under the English system such results are possible as the capture of every seat in Wales (34), in 1906, by the Liberal party, with 217,462 votes, the 100,547 Unionist voters having no representation in parliament.

Proportional Representation.—The attempt to rectify this flaw in the representative method has led to the suggestion of various devices by the adoption of which the elected members may correspond more equally to the divisions of opinion in the electorate. Under the plan of *scrutin de liste* (or "general ticket") larger districts are created, each returning several members, and each voter has as many votes as there are members to elect; but while this system apparently provides the opportunity for the return of candidates with different views, it only requires a solid party vote to capture the whole of the representation for a majority. What is known as the "limited vote" is a form of *scrutin de liste* by which the elector has less votes than there are seats to be filled; with (say) three to be elected, the elector has only two votes. Systems of "limited vote" are in force in Portugal, Spain and Japan. A somewhat better plan is the "cumulative vote," which gives each elector as many votes as there are members to be elected, but allows him to divide them as he pleases (instead of giving only one vote to any one candidate). This enables an organized minority, by concentrating their votes, to elect at all events some representative; but the "cumulative vote" works rather capriciously, and is commonly defeated by careful party organization.

A more elaborate plan, but depending like the "limited" vote and the "cumulative" vote on the formation of constituencies returning three or more members each, is that of the "transferable vote." By this device an elector can indicate on his ballot paper not only his first choice, but also his second or third, etc. To ensure election a candidate need not obtain a majority of the votes polled, but only a certain number, so fixed that it can be obtained by a number of candidates equal to the number of seats to be filled, but by no more; this number of votes is called the "quota." At the first count first choices only are reckoned, and those candidates who have received a "quota" or more are declared duly elected. If all the seats have not then been filled up, the surplus votes of those candidates who have received more than the "quota" are transferred according to the names marked (2) on them. If these transfers still do not bring the requisite number of

candidates up to the "quota," the lowest candidate is eliminated and his votes transferred according to the next preferences, and so on till the seats are filled. This system, which is the one usually associated with the term "proportional representation" was first suggested by Thomas Hare, who published in 1857 a pamphlet on *The Machinery of Representation,* and in 1859 a more complete scheme in his treatise on *The Election of Representatives.* John Stuart Mill, in *Representative Government* (1861) warmly endorsed Hare's proposal. Hare wished to treat the whole country as one constituency, but by later supporters of the "transferable vote" that plan was abandoned as impracticable; and the principle will work so long as the constituencies adopted each return several members. Lord Courtney, in his evidence before the British Royal Commission in 1909, said that his *minimum* constituency would be a three-membered one, but he would create a 15-membered constituency without hesitation. The simple "transferable vote" has been adopted in Tasmania for all elections (1907), after experimental adoption in the constituencies of Hobart and Launceston in 1896–1901, and in the election of the Tasmanian members of the Commonwealth legislature in 1900. It was proposed in the draft of the South African constitution, but abandoned. The principle was also adopted in the "list systems" of Belgium, some Swiss cantons, Sweden, Finland and parts of Denmark, Württemberg and Serbia, where candidates are grouped in lists and all votes given to individual candidates on the list count first as votes for the list itself, the seats being divided among the lists in proportion to the total number of votes obtained by the list.

The principle of proportional representation has been widely adopted in the many new constitutions that have been established in Europe as the result of revolution or secession following on the World War. The most notable is that established in Germany by the Electoral Law of April 27, 1920, for the Reichstag, whereby every party receives a degree of representation corresponding to the number of votes cast in the whole of Germany, one deputy being returned for every 60,000 party votes cast. Minority votes in one constituency are added to the minority votes of the same party complexion cast in another. Article 17 of the *Reich* constitution further imposes the system of proportional representation (*Verhältniswahl*) on the elections to the State legislatures, though the form it has taken differs in the different States. The principle was also adopted by s. 15 of the Government of Ireland Act 1920 and is in consequence in force in Northern Ireland. By Article 26 of the Irish Free State Constitution it has been adopted by the Irish Free State. The extension of the principle in Europe in recent years has been extraordinary. Switzerland adopted it for Federal elections by a referendum to that effect which resulted in its adoption in 1918 in the Constitution. The post-war constitutions of Poland (Art. 11), Czechoslovakia (Art. 13), Austria (Art. 26), make similar provision.

The use of the general term "proportional representation" is, however, somewhat misleading; people often suppose that only one identical system of voting is meant, whereas in fact some 300 possible varieties have been proposed, and each of the States mentioned has a different one from all the others. The only common element is the device of the "transferable vote," *i.e.,* the method of having an "electoral quota," and the filling up of seats, where a quota is not provided by the first choices, by votes transferred from the second choices, and so on. It may be noted here that the "transferable vote" is calculated to multiply candidates to a point at which the minds of the electorate may well be embarrassed as to their preferences (the largest Belgian constituency returns 22 members), and, while undoubtedly providing for "minority representation," to encourage what may be called "minority thinking" and particularist politics. The "transferable vote" is commonly objected to as puzzling to the electors and too complicated for the scrutineers, while it is not much favoured by "machine" party organizations, which generally prefer the simpler plan of rough-and-ready majorities; but it has received a growing amount of theoretical support, as well as success in practical experiment, in recent years.

The Second Ballot.—The "second ballot" is a device for securing absolute majority, instead of relative majority, representation. Where the two-party system prevails, it is usual for only two candidates, one for each party, to stand for each single-member constituency. But there is nothing to prevent a third or even a fourth candidate standing, and this multiplication of candidates becomes the more common in proportion as parliamentary organization is split up into groups. The consequence is that the candidate who heads the poll may well have only a relative, not an absolute, majority of votes, and to meet this objection the "second ballot" has been introduced in several European countries. Under this system, if no candidate receives an absolute majority of all the votes, a second election is held, at which, as a rule, only the two candidates compete who received most; or in cases where more than one seat is to be filled, twice as many candidates compete as there are seats. In principle the second ballot has much in its favour, though it does not necessarily reflect the real opinion of the electorate, but only what is practicable; and while leading to political bargaining it does nothing for minority representation.

In England the importance of the whole subject of the method of elections was recognized at the end of 1908 by the appointment of a Royal Commission to enquire and report. Its conclusions were published in 1910, after much interesting evidence had been taken, but they attracted little attention, being in the main adverse to innovation.

It may be said broadly that all the devices which have been proposed for mitigating or redressing the defects of electoral methods ignore the essential fact that in any case a representative system can only result in a rather arbitrary approximation to correspondence with the opinions of the electorate. It is by no means certain even that "proportional representation" in any of its forms would always result in the return of a representative assembly reflecting with mathematical accuracy the balance of opinion in the electorate; and even if it did, the electors have a way of changing their opinions long before their representatives come up for re-election. It was stated before the British Royal Commission that in Belgium, in spite of "proportional representation," both in 1900 and in 1902 a majority of members was returned by a minority of votes. While under majority rule, as Augustine Birrell once remarked, "minorities must suffer"—even large minorities—it is on the other hand not likely to conduce to the popularity of representative government that minorities should obtain too great a share of political power. Moreover its adoption sometimes, as in Germany, simply results in such a multiplicity of parties, sects and factions as to make a stable Government almost impossible. The fact is that no "representation" can reflect the views of those "represented" as accurately as "presentation" by those entitled personally to speak. This conclusion, while in no necessary degree qualifying the importance of "popular government," undoubtedly detracts from the value of the representative method. The result is seen in the increasing desire in really democratic countries to supplement representative government by some form of Referendum, or direct appeal to the electors for their own personal opinion on a distinct issue—a method which involves fundamentally the addition of a "presentative" element to the representative system.

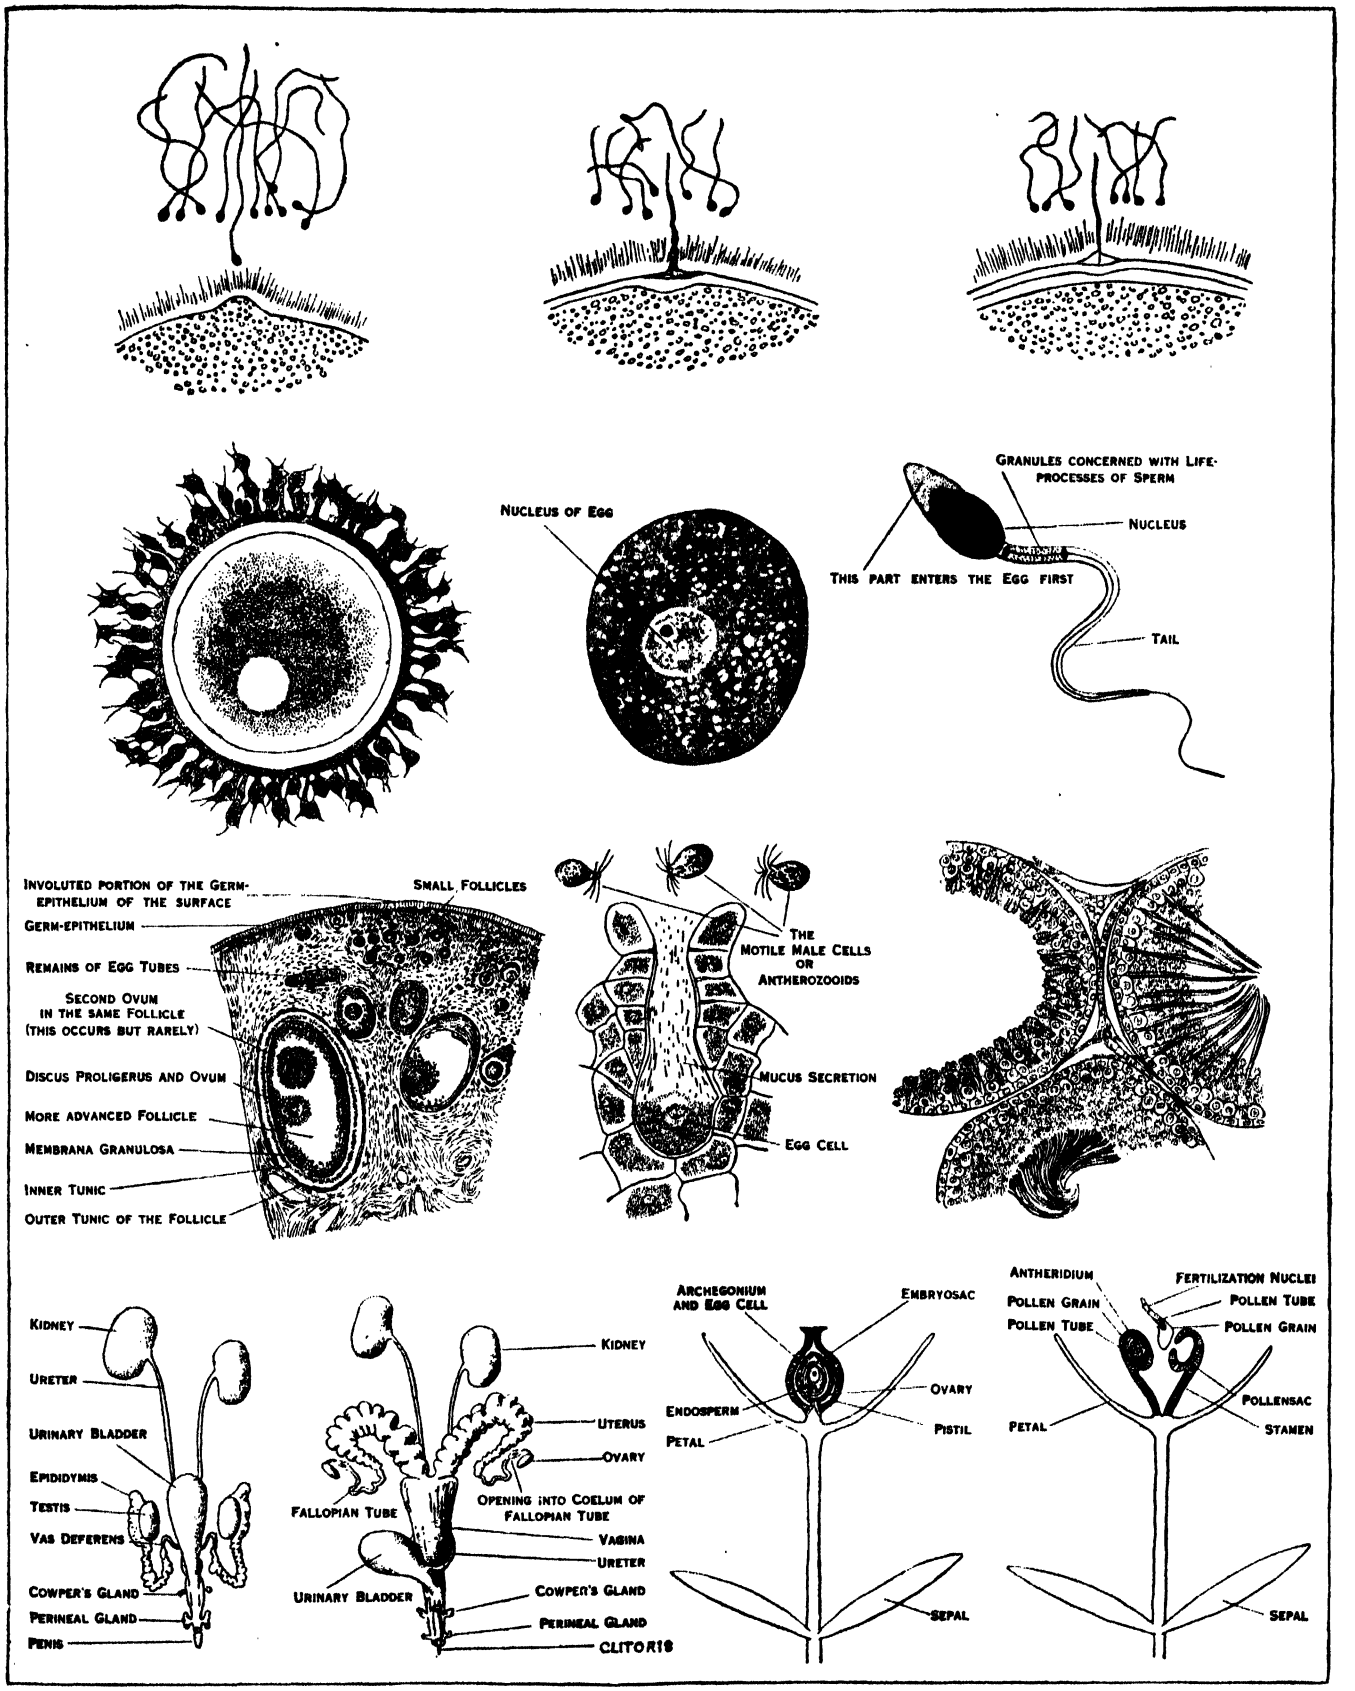
Alike in the British empire and the United States, in contrast to European countries, popular opinion is against the innovation of proportional representation. Queensland and certain western provinces of Canada as also the western States of the U.S.A. have shown a definite preference for the "referendum." This device, *i.e.,* the reference of bills passed by a representative legislature to a plebiscite of the whole electorate, is, of course, not an extension of the representative principle, as expressed in schemes of "proportional representation," but a direct contradition to it, as it implies that the "representative" legislators, even when elected on the principle of "proportional representation," are not sufficiently "representative" of the will of the people to make their action in the legislature binding on the latter. Yet the fact that the very countries or some of them, such as Germany and Switzerland, which have adopted "proportional representation," have also adopted or retained the "referendum" seems to indicate doubt as to the perfectibility of proportional representation.

BIBLIOGRAPHY.—The best discussion of the various methods for securing adequate representation is now to be found in the *Report* (1910) of the British Royal Commission on Systems of Election (Parliamentary Paper, Cd. 5,163). It is chiefly valuable for its description of the devices in use in different countries and for its weighty criticism of the proposals for minority representation. Among other authorities may be mentioned the following: J. H. Humphreys, *Proportional Representation* (1911); Ostrogorski, *Democracy and the Party System* (1910); Beard and Schultz, *Documents on the Initiative, Referendum and Recall* (1912); Gierke, *Political Theories of the Middle Age* (Maitland's translation, 1900); J. H. Humphreys, *Practical Aspects of Electoral Reform* (1923); Sir J. Fischer Williams, *The Reform of Political Representation* (1918); C. G. Hoog and G. H. Hollett, *Proportional Representation* (1926); Charles Seymour and D. G. Frary, *How the World Votes* (1918). (H. C.; X.)

REPRISALS, acts of retaliation by one belligerent to compel the other belligerent to refrain from committing unlawful acts of war, and to comply with the recognized laws and customs of war. Reprisals should only be taken in the last resource. They should not be excessive and in no case be of a barbarous character. They should consist of a repetition of the same or similar acts, and, so far as possible, should be inflicted, not vicariously, but on the actual wrongdoer. The only authoritative rule is to be found in the *Oxford Manual of the Laws and Customs of War on Land* (1880) of the Institute of International Law. For the extent to which neutrals may be involved in reprisals, *see* NEUTRALITY.

Certain measures of redress, short of war, are also termed reprisals. At the present time they usually take the form of the occupation of a port or some part of the territory of the offending state, or the seizure of its customs duties, or the detention of its vessels lying in the territorial waters of the injured state, or the institution of a pacific blockade (*q.v.*).

See P. Cobbett, *Leading Cases on International Law* (1885); A. D. McNair, *The Legal Meaning of War and the Relation of War to Reprisals,* Grotius Transactions vol. ii. (1926).



REPRODUCTION. The general term Reproduction includes the whole sequence of processes or events by which new individuals arise and life is continued from generation to generation. It is often and rightly said that the major activities of organisms centre round the contrasted functions of nutrition and reproduction, using both terms widely. Yet it is evident that nutrition and reproduction are not necessarily two sharply circumscribed single functions, but may imply the direction of numerous activities towards two particular ends, the preservation of the individual, on the one hand, and the continuance of the race, on the other. In studying higher animals, it is impossible to consider either reproduction or nutrition apart from the functions of moving and feeling, or apart from circulation and the hormones. Many functions may be ancillary to reproduction, which means much more than the activity of the reproductive organs or gonads. Moreover in the higher reaches of life, reproduction has its psychological as well as its physiological aspect.

The antithesis between nutrition and reproduction, however, is one of the fundamental ideas in biology. Nutrition not only implies fuel for immediate consumption, it implies increase of capital, whether in growth or reserves. It has emphatically a plus sign, whereas reproduction is always minus, since it means parting with some of the living material, and the sacrifice is sometimes enormous. Yet the antithesis must not be pressed too hard. As Haeckel emphasized, reproduction may be regarded as a form of discontinuous growth, specialized for multiplication; and growth is the outcome of nutrition. In asexual modes there is a separation of surplus material accumulated by antecedent nutritive processes. Even in sexual reproduction an elaborate nutritive preparation is often necessary, as in the equipment of a huge number of eggs with yolk.

What Reproduction Implies.—In the simplest case reproduction is complete in one act—the division of a microbe into two. But this is not typical of higher forms. (*a*) Very generally reproduction implies the differentiation of two sexes, the egg-producing female, and the sperm-producing male; and with this many degrees of sex-dimorphism may be associated. Sexual fusion, however, is primarily not reproductive (*see* SEX). (*b*) At a certain age or under certain environmental, *e.g.*, seasonal, stimulation the reproductive organs become active,—a process which may be linked to other physiological changes in the body generally. But biology is still far from an understanding of the physiological processes which lead, for instance, to the activation of a wild bird's gonads in spring. For most of the year they are in abeyance, sometimes hardly visible on dissection, but suddenly they become large and the seat of rapid multiplication of cells. In some animals a special diet is required to activate the gonads; thus in some Diptera a meal of blood is necessary. Especially as regards Algae and small crustaceans, much is known in regard to the environmental conditions that bring on reproductive activity, but generalization is still very difficult. (*c*) While the gonads are influenced by the body, there is also a converse influence. For hormones which are produced by the testis or by the ovary are distributed by the blood throughout the body, and serve to provoke new growths, such as antlers, or to excite previously inactive organs, such as milk-glands. (*d*) In a great variety of animals there is a well-marked phase in which the sexes become aware of one another as desirable, or as opportunities for satisfaction, and seek to secure sexual union, sometimes coercively, but often by evoking mutual interest and excitement. This is a prelude to actual pairing, and it often attains to some artistic subtlety (*see* COURTSHIP OF ANIMALS). (*e*) The outcome is the actual liberation of the sperms on the male's part, which may or may not be simultaneous with the liberation of ova on the female's part, as in the cases of frogs and bees respectively. But all sorts of modes occur. The sexes may not see or touch one another, yet there may be simultaneous liberation of eggs and sperms, as in sea-urchins, where the actual fertilization in the water is very fortuitous. In diverse fishes, though there is no physical contact between the sexes, the proximity of the spawning female is necessary as liberating stimulus to the male's emission of sperm. On the other hand, at many different levels, as from dragon-flies and crabs to birds and mammals, there is some sort of sexual embrace or amplexus in the course of which the sperms pass from male to female. As in other successions of events among organisms, there may be in reproduction an entire suppression of a chapter that is more or less typical of the ordinary trajectory of life. Thus most marine fishes suppress insemination—a term which should be restricted to the transference of sperms from the male to the female, or from one hermaphrodite to another, as in earthworms and snails.

(*f*) But whether there is insemination or not, there is in the great majority of animals the essential process of fertilization, the intimate and orderly union of the sex-cells. (For exceptions, *see* PARTHENOGENESIS.) As the nuclei of the ripe gametes have undergone meiotic division, the process of fertilization restores the number of chromosomes to the normal. It also implies the union of the paternal and maternal hereditary factors, a stimulus to the egg-cell to divide, and a blocking of the egg-cell against other sperms. (*See* FERTILIZATION.) In flowering plants the process of pollination would roughly correspond to insemination in animals, while the union of the microscopic male nucleus from the pollen-tube with the microscopic female nucleus in the egg-cell within the ovule's embryo-sac, is the act of fertilization. In flowerless plants and in the primitive flowering plants known as Cycads and Gingkos, the male cell is a locomotor sperm (antherozoid) as in most animals.

(*g*) Development (*see* EMBRYOLOGY)—the process by which the fertilized ovum builds up an embryo—is a study by itself yet it cannot be rigidly separated off from reproduction, for it is through development that the organization of the parents is reproduced. Moreover, there is the peculiar occurrence of polyembryony in some armadillos, e.g., *Dasypus novemcinctus*, and in some parasitic Hymenoptera, e.g., *Encyrtus*, where the developing egg normally produces several embryos, which is obviously a process of multiplication. It would also be pedantic to try to exclude from the rubric of reproduction the various ways in which the maternal parent contributes to the development of the offspring while it remains within her body. In the gestation of ordinary mammals the placenta establishes what may be called a

symbiotic relation between the mother and the offspring; and of this, as Aristotle knew, there are anticipations even at the level of dogfishes. Hints of ante-natal linkage and nutrition are also seen in a few reptiles and even in the primitive Onychophora (*q.v.*). (*h*) The study of reproduction must also join hands with the study of heredity,—the relation of organic continuity between successive generations, which tends to secure the begetting of like by like; and this is particularly the case when there is an intimate linkage between mother and offspring (or between the plant and its seed!) supplying the early "nurture" required if the hereditary "nature" is to express itself aright. (*i*) Nor can we exclude a consideration of the diverse ways in which the new generation is separated from the old, whether by buds and fragments, or by ova, or by ova that have developed before liberation into larvae or into miniature organisms. And this may be complicated by the occurrence of alternation of generations. (*j*) Finally, biology cannot be content with a study of reproduction as a problem in the physiology of the individual, or even of the pair. There is a higher physiology or ecology of reproduction, which concerns itself with such questions as monogamy, polygyny and polyandry (as in the cuckoo) and with the different forms of animal family (*see* SOCIOLOGY, ANIMAL).

Modes of Reproduction in Unicellular Organisms.—Among one-celled organisms, whether protists, Protophyta, or Protozoa, the unit divides into two or more parts (by equal fission, or by giving off small buds, or by spore-formation); and each of these parts grows into the likeness of the whole. In the great majority of cases, the division of the unicellular organism is preceded by the division of the nucleus, and in some types this division takes the form of intricate mitosis (*q.v.*). Yet there are some cases, such as the production of multiple buds around the margin of *Arcella*, or the very rough-and-ready fragmentation described in *Schizogenes*, where reproduction does not seem to be far removed from rupture. In all cases of division there is probably some plasmic instability within the cell, which leads to cytolysis; and it was perhaps one of the early tasks of organic evolution, so to speak, to regularize this disintegration, so that it led not to death, but to more life. The plasmic instability, which modern biochemistry and bio-physics are seeking to define, may be the natural outcome of growth. For it was pointed out by Herbert Spencer and Rudolf Leuckart that a growth-increase in the volume of living matter is not accompanied in regular shapes by a *pro tanto* increase in the surface by which the processes of keeping alive are effected. Thus in spheres, the volume increases as the cube of the radius, while the surface increases only as the square. The consequences of this may be partly evaded, as in Rhizopoda which acquire a large surface by flowing out in numerous pseudopodia; but the general idea is sound. And in addition to the volume-surface ratio, there is the relation (emphasized by R. Hertwig) between nucleoplasm and cytoplasm, which seems to have its optimum and its limits. When the cell divides, there is a reduction of volume, but a relative increase of the surface. Or there may be an adjustment of the ratio between nucleoplasm and cytoplasm; and in this connection the not infrequent occurrence of multiple nuclei should be considered. Of interest are the experiments of Gruber who showed that excised non-nucleated fragments of some Protozoa, which may live for a time and even show growth and repair, eventually fail to survive, the nucleoplasm, in some form or other, being apparently essential. It is suggested, then, that the beginnings of multiplication are to be looked for in cell-rupture following instability.

But reproduction among unicellular organisms must be looked at from another side,—that of fertilization or, to use Weismann's term, amphimixis. It is said that isolated cells sometimes flow together when exhausted, forming a small plasmodium. This has been described in the poured-out coelomic fluid of sea-urchins where moribund cells club together and survive for a time in small groups or plasmodia, not to be confused with clots. A somewhat similar viable coalescence of amoebulae was described by Haeckel in *Protomyxa*, and occurs in some Myxomycetes. From such plasmodium-formation it is but a step to multiple conjugation, as seen in some Heliozoa and other Protozoa, and also in some Algae (*q.v.*). A giant amoeba, in the genus *Pelomyxa*, may be artificially built up by mingling two together with a needle, and then carefully adding a third and a fourth. Of common occurrence is the total conjugation of two indistinguishable units (isogamy) as in the large infusorian *Noctiluca*, or of two unequal units (anisogamy) as in *Vorticella*. In many Protozoa, as in radiolarians, specialized reproductive units (gametes) are produced by the division of the ordinary vegetative units. They are often dimorphic, and unite in pairs to form a zygote, which either grows into the original form, or proceeds to divide into many individuals.

Very suggestive, but on a special line, is the "partial conjugation," familiar in *Paramaecium* and its relatives, where the two conjugants, after a process of nuclear reduction, pointing on to polar-body formation in ova and a similar meiotic division in spermatogenesis, exchange micronuclear elements and then separate, the sequel being nuclear reconstruction in the ex-conjugants. This partial conjugation, obviously a sexual rather than a multiplicative process, possibly increases the vigour and certainly promotes the variability of the stock.

In artificially isolated "pure lines" (all descended from a single *Paramaecium* by generation after generation of fission) no conjugation occurs, and one would not expect any, since they are all the same. In ideal conditions, *e.g.*, as regards aëration, food-supply and the removal of waste-products, there seems to be no limit to asexual reproduction. In L. L. Woodruff's famous experiments the sequence of vigorous asexual generations was continued, without conjugation, for over ten years. But in these optimum artificial conditions, and in natural conditions for certain species (e.g., *Paramaecium caudatum*), there is a periodic, it may be monthly, occurrence of a remarkable process (endomixis) in which the nuclear organization is disintegrated and then re-constructed. The individual slipper animalcules, to give them their popular name, behave as if they were going to conjugate with one another. As in the pre-conjugation phases, there is a scrapping of the dimorphic nuclei, but no conjugation occurs, and reorganization follows. The disintegration and the re-integration here suffice to secure the continuance of vigour. In other Protozoa, however, in which endomixis never occurs, M. Hartmann has been able to obtain a similar indefinite continuation of asexual reproduction. These observations of Woodruff and Erdmann have, like most thorough observations, a significance far beyond the immediate subject-matter. Throughout the whole gamut of organisms there is a contest between life and death, that is to say between the individual conservation and the individual disintegrative loss of energy. To put it in another way, there are processes in the living organism that tend towards senescence (to be distinguished, as far as may be, from the diurnal running down of the clock); and there are counteractive processes that make for repair, recuperation, and rejuvenescence. In short, there are processes of aging and processes of regaining youth.

In senescence it is not the living matter itself that gets worn out; it is rather the less labile framework of the cells; the furnishings of the laboratory, rather than the workers. This universal senescence-versus-rejuvenescence contest, is to be distinguished as far as may be, not as if they were *au fond* different, from the normal and continual recuperation of katabolism by anabolism. An organism may be balancing expenditure and income every day, and yet there may be a serious depreciation of property. This is senescence, and there are various ways in which rejuvenescence-processes stave off the evil day of insolvency. In *Paramaecium* one of these rejuvenescent processes is endomixis, and it may be that in the subtler and more intimate modes of reproduction at higher levels, some rejuvenescence is effectively secured by rearrangements. In Polyzoa, for instance, there is a collapse of the fatigued individual into a "brown body," from a bud of which, after rest and re-integration, a vigorous new individual arises.

Modes of Reproduction in Multicellular Organisms.—(A) Many forms of asexual increase occur in multicellular plants and animals, with this in common that a considerable portion of the parent is separated off, though not necessarily liberated, to form a new individual. Thus the freshwater *Hydra* gives off buds; a sea-anemone may split longitudinally into two; a nemer-

tine worm may break into several viable pieces; there are two or three starfishes that actually multiply by separating off their arms; a liverwort may produce minute multicellular gemmae which float away in runlets of rain; a tiger-lily drops its bulbils; and a strawberry plant sends out runners, which root and form independent individuals at well-spaced intervals. In many cases the asexual multiplication leads to the formation of physically continuous colonies, as in zoophytes and corals, Polyzoa and compound tunicates; while many hydroids, such as *Obelia*, illustrate the formation of polypoid buds which remain members of the colony, and medusoid buds which are set adrift as sexual swimming-bells. It is certain that a knowledge of metabolic gradients (*see* AXIAL GRADIENTS) will explain, as is already being indicated, why there should be at particular places in the organism lines of weakness, or reductions in the intensity of metabolism, or processes of cytolysis, which bring about the separation of a bud or a bulbil, or the breaking of a worm into viable pieces.

But the large fact is that all the Metazoa and the great majority of the Metaphyta, exhibit sexual reproduction, though the asexual mode may be retained. The chief mode of multiplication in *Hydra* is by separating off asexually produced buds, but there is also sexual reproduction by ova and spermatozoa. But in this case the relative unimportance of the sexual method, as far as multiplication of these polyps is concerned, is emphasized by the fact that the ovary contains only one mature egg, and that there is usually only one ovary. The highest animals to show asexual multiplication regularly and in the adult stage are the Tunicata. Thus in the salps, a solitary "nurse" buds off a chain of sexual individuals, which eventually separate. This case is interesting since the tunicates have reached a high degree of structural complexity. Twinning by division of a single egg or embryo is a form of asexual reproduction confined to the developmental period.

(B) The term "sexual reproduction" covers several distinct facts: (1) the formation and segregation of special reproductive cells, as contrasted with those of the body or "soma" generally; (2) the differentiation of special reproductive cells, usually the dimorphic egg-cells and sperm-cells, the latter non-viable except in fertilizing the former; (3) the typical production of these specialized reproductive cells by different (male and female) organs or individuals. But to these three statements it is necessary to add several saving-clauses. (1) In many plants, most clearly in vascular cryptogams like ferns, one phase in the life-history has to do with the production of spores. These are special reproductive cells which develop without fertilization. Thus those that fall from the sporangia on the back of a fern-frond develop into small sexual prothalli (gametophytes). The egg-cell of a prothallus fertilized by a sperm-cell (or antherozoid), develops into an ordinary fern-plant (the sporophyte); and the life-history thus illustrates alternation of generations. This may be defined as the alternate occurrence in one life-history of two or more different forms differently produced. Spore-cells may also occur among multicellular animals, as is seen in the life-history of the liver-fluke, where two larval stages (sporocysts and rediae) multiply by spore-cells, which are hardly differentiated enough to be called parthenogenetic ova, while the adult fluke reproduces by ova and spermatozoa as usual, except that self-fertilization or autogamy occurs. (2) In some animals, such as certain rotifers, the males are unknown; in other types, *e.g.*, summer green-flies, they may be absent for long periods; in other cases, such as certain gall-flies, the males are unnecessary even when present. In other words, parthenogenesis (*q.v.*), is common. Yet this launching of an unfertilized ovum on the voyage of development should be retained under the rubric of sexual reproduction, for although there is no fertilization, there is multiplication by means of egg-cells. (3) Many common animals, such as snails, earthworms and leeches, are hermaphrodite, each individual having both ovary and testis, which often ripen at different times (protandrous and protogynous dichogamy). In the cases mentioned there is cross-fertilization in spite of the hermaphroditism; in rare cases, such as the liver-fluke and some tapeworms, there is self-fertilization or autogamy. To be distinguished from thoroughgoing hermaphroditism is the normal reversal of sex in the course of the animal's life. Thus among cymothoid and epicarid crustaceans, the females pass through a male phase, though they may not function as such. According to Cunningham and Nansen all the smaller hags (*Myxine*) have a testis, which is subsequently replaced by an ovary. (*See* SEX.)

Advantages of Sexual Reproduction.—Since most multicellular plants and animals exhibit sexual reproduction, either exclusively or along with a retained asexual multiplication, the question rises as to the advantages of the sexual process. (*a*) That sexual reproduction is fatal to the individual in many cases, *e.g.*, butterflies and eels, does not contradict the general proposition that sexual multiplication is physiologically more economical than the asexual modes when there is a large number of progeny.

(*b*) Although asexual multiplication may occur in complicated animals, such as tunicates, it would be attended with obvious difficulties in many of the highly differentiated and integrated types, such as arthropods and vertebrates.

(*c*) The outstanding fact implied in having specialized reproductive units is that these have not shared in the building up of the parental "body," but have retained an organization (or equipment of hereditary factors) continuous in quality with that of the original fertilized egg-cell from which the parent arose. They are thus not very liable to be tainted by any of the mishaps which are likely enough to befall the "body" or "soma" which bears them. This gives them an advantage over buds or fragments, for these are liable to start with such disabilities as the parental body may have acquired. Plants, such as potatoes, that are artificially propagated by means of cut-off pieces, are apt to lose their good qualities in the course of a number of asexually-produced generations.

(*d*) In the course of the life-history of the germ-cells, in the processes of final maturation, and in the mingling of hereditary factors that is effected in fertilization, there are opportunities for new permutations and combinations. Here is the crowning advantage of sexual reproduction, that it favours, more than the asexual process, the emergence of new variations.

(*e*) Without falling into a teleological fallacy, we may look further ahead and recognize that sexual reproduction among animals leads to dimorphic and separate sexes, whence follow courtship and the dawn of the love of mates. Sexual reproduction has been a factor in evolution, as regards, for instance, the emotions, family life and speech. The first use of the voice was doubtless as a reproductive call. One does not, of course, account for origins by indicating the advantages accruing from the steps taken, but it is legitimate to point to consequences as well as origins.

Nutrition and Reproduction.—Growth tends to occur when nutrition is in excess of what is required for everyday recuperation. In unicellular organisms the limit of growth is in most cases quickly reached, explicable exceptions occurring in special cases, such as giant Foraminifera, where there is a large pseudopodial surface. The frequent multiplication of unicellular organisms has its counterpart in the frequent cell-divisions that occur in the developing Metazoa and Metaphyte (multicellular organisms). But in most Metazoa there is a more or less definite limit of growth—the physiological optimum of size. Further growth is apt to be attended by the setting in of some detrimental instability, and it is after the limit of growth has been reached that reproduction usually occurs. Special explanations are needed for peculiar phenomena like precocious reproduction or paedogenesis, as in the liver-fluke, the gall-midge *Miastor* (in which there are larvae within larvae), and some Urodela, e.g., *Amblystoma* and occasional newts. It should also be noted that some fishes and reptiles seem to have no limit of growth, and have a very prolonged succession of breeding periods. When the nature of the organism allows of a very large surface in proportion to size, as in trees, there seems to be no definite limit of growth. On the whole, however, the proposition stands that reproduction does not usually occur until the limit of growth has been reached.

Abundant nutrition favours asexual multiplication, but a check to the nutrition may bring about the separation of the buds. A simple illustration may be found in *Hydra*, where a bud often produces buds of its own. Eventually a check to nutrition occurs

and the buds drop off; and this may be followed by a phase of sexual reproduction. Similarly a planarian worm in good nutritive conditions may form asexually a chain of four; if a check to nutrition occurs, the links separate; and sexual reproduction may set in. Vigorously growing fruit-trees are often root-pruned because the check to nutrition favours the reproductive activity of flowering and fruiting. But if foliage and vegetative activity are desired, it may be useful to nip off the flower-buds. Other things equal, abundant nutrition favours asexual multiplication, but the formation rather than the separation of buds. On the other hand, a check to nutrition may act as a stimulus to sexual reproduction.

Individuation and Genesis.—The rate of reproduction depends (*a*) on the constitution of the individual organism, and (*b*) on its immediate environment and nutrition. It is high in green flies and rabbits, low in golden eagles and elephants. The actual rate of increase, which is much more difficult to estimate, when a periodic census is not readily practicable, depends on the wide and complex conditions of life which are summed up in the phrase "the struggle for existence." Organisms sometimes show an extraordinary increase in numbers in favourable areas and seasons, witness plagues of voles or locusts; and in exceptional cases, where food continues abundant and checks continue to be slight, the increase may go on for many years, as with the rabbits in Australia or the potato beetles in North America. But in most of the cases known to-day the sudden floods of life soon cease. The increase meets checks of famine and weather and enemies, and a balance is automatically restored.

Similarly, when the rate of increase fails to meet the elimination, there may be sudden rarity, as with the tile-fish, and even sudden extinction, as with the passenger pigeon. But in most cases there is an automatic adjustment of the balance; thus the sudden decrease may relieve the intra-specific competition, so that the mortality among the young stages is greatly reduced. Slight fluctuations in numbers are much commoner than sudden increases or decreases.

Reference must be made here to Herbert Spencer's thesis that reproductivity tends to decrease in the more highly evolved organisms. Including under the term "individuation" all the race-preserving processes by which the individual life is completed and maintained, and under the term "genesis" all the reproductive processes that lead to the formation of new individuals, Spencer maintained that individuation and genesis vary inversely. Genesis decreases as individuation increases, but not quite so fast; in other words, progressive evolution in the direction of individuation is correlated with a diminished rate of reproduction.

In support of this conclusion Spencer adduced some general physiological reasons why individuation and genesis should vary inversely, and he brought forward inductively a number of instances of poorly individuated types, like tapeworms, that are very prolific, and of highly individuated types, like golden eagles, that show greatly economized reproductivity. But he did not prove that high individuation directly lessens fertility. What is much more probable is that highly individuated types have resources which have enabled them to reduce the ratio of elimination, and have thus allowed them to vary in the direction of economized reproductivity without decreasing their chances of survival. In mankind the psychological and social factors in individuation may operate directly in lessening pre-occupation with sex-indulgence and in lessening in monogamous married life, the physical incentives thereto, thus resulting in smaller families, but there is no proof that education or the like physiologically lessens fertility.

Reproduction and Death.—While reproduction is concerned with the beginning of new lives, it is not infrequently associated with the death of the parent. In many organisms reproduction is the beginning of death, and the connection may be either direct or indirect. (*a*) In some Annelida, for instance, the multiplication of germ-cells distends the body and leads to fatal rupture, which is checkmated in the Palolo worms by the sacrifice of the bulk of the body, while the head end remains in a crevice of the coral reef and regrows a new body for the next season. Apart from the bursting of the body—a somewhat crude nemesis—a fatal strain on the constitution of the animal may result from the amount of nutritive material required for the equipment of the eggs, and from the fatigue involved in liberating either the eggs or the embryos. In the male the tumescence in the reproductive organs and, in vertebrates, the erotization of the body by reproductive hormones may lead to an orgasm so violent that it is sometimes fatal. Both sexes of the fragile butterfly and of the stoutly built marine lamprey pay for their reproduction with their life. Among higher vertebrates there is a marked reduction of the physiological expensiveness of the reproductive process. The too familiar tragedy of the human mother's death in childbirth is an exception, due partly to the increase of brain size in man with consequent enlargement of the infant's head, partly to the unhealthiness of civilized life.

(*b*) But there is an indirect way in which death has come to be associated with reproduction. There is abundant evidence that the length of life, within certain limits of constitution, is adaptive. In the course of ages of natural selection the duration of life has been automatically adjusted to the survival-welfare of the species, and it is vitally important that reproduction should occur when the organism is in full vigour. It is against the welfare of the species that organisms should reproduce after they are long past their best, and this is one reason why animals die after they reproduce. As Goethe said, death is nature's device for securing abundance of life.

REPRODUCTION, PHYSIOLOGY OF. It is common knowledge that the majority of animals and plants have more or less definite times at which they breed, though the ova (estimated at 100,000 in man) are probably preformed at birth. These depend often upon seasonal or environmental conditions and it is well known that spring and summer are the times for reproductive activity among birds, insects and a host of other animals. Unusual warmth or cold may hasten or check the periodic development of sexual activity and the accompanying internal and external changes which take place in the body. The connection between breeding and food supply is also generally realized. Moreover, where climatic and nutritive conditions are approximately uniform throughout the year, periodicity in the breeding habits of animals is often obliterated. Thus, Semper states that sexual periodicity is absent among molluscs, insects, and other land animals in the Philippine Islands. On the other hand, the regularity of the migratory movements, which directly relates to changes in the reproductive organs and the instincts for breeding, occurs to a great extent independently of temporary climatic conditions, though not wholly so. (*See* MIGRATION OF BIRDS.) It is clear, however, that, broadly speaking, the factors which control the periodic changes in the generative system in association with breeding are of two kinds, the external ones referred to above, and internal factors inherent in the animals themselves, and particularly in the essential reproductive organs. Before attempting to describe these changes and the manner in which they occur it will be well, briefly, to describe the reproductive organs, referring more particularly to the higher animals.

The Generative System.—Amongst vertebrates the sexes are nearly always separate, although a few species are hermaphrodite. The usual arrangement, however, is for each individual to have its own characteristic sexual organs, those of the other sex, if represented at all, failing to develop or undergoing early degeneration. In the male of all lower vertebrates (including birds) the *testes* lie dorsally inside the body cavity and discharge their products, the spermatozoa, along with fluid secretions, into ducts communicating with the exterior by a passage (the *cloaca*) common to the urogenital and alimentary systems. In most mammals,

on the other hand, the testes lie outside the main body cavity in a double sac (the *scrotum*) between the anus (or opening of the gut) and the penis. The testes are largely composed of tubules whose walls give rise to the spermatozoa and these latter are budded off into the interior as in other animals. Between the seminiferous tubules are *interstitial cells*. These give rise to chemical substances (hormones, *q.v.*) which pass internally into the blood. (*See* ENDOCRINOLOGY.) There is strong evidence that these internal secretions by their power of stimulation are responsible for the growth and development of the distinctively male characters and instincts. Thus, the presence of the testes is commonly regarded as the test for maleness.

In all mammals the spermatozoa pass out from the testis by a number of short ducts (the *vasa efferentia*) into a coiled tube lying alongside it (the *epididymis*). This acts as a storehouse for the spermatozoa until they are ejaculated. Spermatozoa may remain alive within the epididymis and still be capable of fertilizing ova for 30 days (rabbit). The epididymis is a long coiled tube with muscular walls and the coils lie in juxtaposition so that the whole forms one discrete body closely applied to the testis. From each epididymis a duct (the *vas deferens*) passes back through the *inguinal canal* (a passage connecting the scrotum with the body cavity). The two vasa deferentia open close together in the common channel with which the urinary bladder also communicates. This passage (the *urethra*) is continued within the erectile copulatory organ or *penis*, at the end of which it opens to the exterior. In addition to these organs there are several accessory glands communicating with the common urogenital passage. These are the *seminal vesicles*, the *prostate gland* and *Cowper's glands*, all of which contribute fluid substances to the semen in which the spermatozoa swim; the secretions are believed also to cleanse the urethra of urine prior to the ejaculation of semen. The above description applies more especially to man, but in the majority of the lower mammals the organs are similarly arranged.

The ovaries, the essential reproductive organs of the female, likewise serve a double function. They produce the ova and also elaborate internal secretions comparable to those of the testes; these secretions are responsible for initiating the development of the female characters, as well as being a necessary factor in the sexual and reproductive processes. In the lower vertebrates the ova are large owing to the amount of food substances (yolk) contained in them (as with the egg of the fowl), but in mammals they are microscopic, each being about $\frac{1}{130}$ in. in diameter (this, however, is considerably bigger than a spermatozoon, which is about $\frac{1}{500}$ in. in length). The ova are contained within little sacs (Graafian follicles). These begin by being very small, but as they approach maturity their cavities enlarge until they protrude from the surface of the ovary; eventually (unless, as often happens with some of them, they have degenerated) they discharge their ova to the exterior in *ovulation*.

The ovaries are attached, one on either side, to the dorsal wall of the abdominal cavity by the *broad ligament*. The tubes which convey the ova to the exterior are also suspended by this ligament, a double fold of tissue arising from the wall of the body cavity. In the lower vertebrates the oviducts are provided with glands secreting albumen or egg-white which coats the ovum as it passes down the tube. The egg-shell in those animals in which it is formed is also secreted by a gland; in birds this is at the posterior end of the oviduct just in front of where it opens into the common urogenital passage. At the anterior end each oviduct has a fimbriated trumpet-shaped aperture which expands at ovulation and receives the eggs as they pass into the body cavity. The interior of the expanded end is provided with cilia which direct the passage of the ova into and down the tubes. The oviducts are usually paired to correspond with the ovaries, but in birds only the left ovary and oviduct are present. In mammals and birds the ova are usually fertilized by the spermatozoa in the passage of the oviduct, but in the lower vertebrates (*e.g.*, most fish) this often occurs outside the body. In mammals, the oviducts (small somewhat coiled tubes) swell out posteriorly to form the *cornua uteri*, or womb. These may continue double throughout their entire length and open separately into the vagina (rabbit) or after continuing separate for a considerable distance may unite together to form the *corpus uteri* or body of the uterus (cow, sheep, mare, bitch, etc.) or they may extend for only a short distance before opening into the corpus uteri, which is a sac or bag (man). At the hind end the corpus uteri narrows down to form a neck (*cervix*) and this opens into the vagina by the *os uteri*. The uterus is the organ which contains the developing young during pregnancy. It has thick muscular walls on the outside and a mucous membrane with numerous glands lining the cavity inside. These secrete a fluid which helps to nourish the developing embryo during pregnancy and supplies a medium in which the spermatozoa swim after copulation. The *vagina* is the broad urogenital passage which extends backwards through the pelvis and opens to the exterior at the *vulva*. The latter is constituted by all the female generative organs visible externally. The lateral boundaries are the *labia* or lips. The *clitoris* is a small rod-like erectile structure and corresponds to the penis of the male but is solid.

The mammary glands, although not directly concerned with the reproductive processes, are dependent upon the ovaries for growth. They consist of milk-secreting tissue and are provided with ducts which convey the milk to the nipple, whence it can be drawn off.

The Reproductive Cycle.—At the approach of the breeding season in most animals the gonads (testes and ovaries) undergo marked growth. This is very pronounced in fishes and is hardly less marked in birds. Thus in the sparrow in winter the testis is no larger than a grain of mustard seed but at the breeding season it reaches the size of a small cherry.

The male breeding season, when it occurs, is called the season of *rut*. The increase in the size of the testes which occurs prior to rut is accompanied by activity not only of the cells which give rise to the spermatozoa (the spermatogenetic tissue of the seminiferous tubules) but also of the interstitial cells. In some mammals the testes are not permanently retained in the scrotum but descend thither at the beginning of rut and are withdrawn into the abdomen again after the rutting season is over (*e.g.*, many rodents). In insectivores (*e.g.*, mole and hedgehog) the testes descend periodically into temporary receptacles. In the mole it is estimated that the testes increase in size 64 times, and the seminal vesicles, prostate and other accessory glands likewise show enormous growth. The time for sexual intercourse is continuous throughout rut, there being no short periods of quiescence within the breeding season as in the females of many species. Amongst domestic animals generally there is no special season of rut, the male being capable of service throughout the year, the semen evacuated normally containing an abundance of spermatozoa. In this respect these species differ from their wild ancestors, for in the undomesticated state the male usually experiences a rutting season at the same time as the breeding season in the female.

In the female mammal the times for sexual intercourse, instead of extending continuously over a season of considerable duration, as with the male, are restricted to periods of "heat" or oestrus. These may recur at rhythmical intervals within one breeding season (mare, cow, ewe, sow) or there may be only one oestrus to the season (bitch). The former condition has been described by Heape as polyoestrous, the latter as monoestrous. The whole cycle of changes is known as the oestrous cycle. In the case of a typical monoestrous mammal, such as the dog, the oestrous cycle is divided as follows: anoestrum (period of rest); prooestrum (period of growth and preparation); oestrus (period of desire); pregnancy or (alternatively) pseudo-pregnancy.

During the anoestrum the reproductive system is, relatively speaking, quiescent. The Graafian follicles which contain the ova probably undergo slow growth and ripening, but they do not become conspicuous upon the ovarian surface until near the end of the anoestrum. The uterus is relatively anaemic and the glands inactive. The mammary glands are also inactive unless lactation is in progress after recent pregnancy. The entire anoestrum in the bitch lasts about three months.

The prooestrum is marked by increased activity of the genera-

tive system generally. It is the time of "coming on heat." The follicles come to protrude visibly from the surface of the ovaries. The uterus also undergoes growth, the blood vessels increase in size and number, and the glands in the mucous membrane elaborate more secretion. At a slightly later stage a definite haemorrhage occurs in the uterus and blood is passed out to the exterior at the vulva. The mammary glands may also become slightly congested. The entire prooestrum lasts from one to two weeks and external bleeding may go on for ten days, but it is usually slight, consisting of no more than a sanguineo-mucous flow.

Oestrus or "heat" is the period at which (and, ordinarily, only at which) sexual intercourse takes place. It is marked internally by ovulation, that is, the rupture of the Graafian follicles and the discharge of the ova, which then become mature and ready for fertilization by spermatozoa. The wall of the uterus undergoes repair at this time but the glandular secretion is abundant and more liquid in character, to provide a suitable medium for the spermatozoa. In the bitch oestrus lasts about a week.

Oestrus is succeeded by either pregnancy or pseudo-pregnancy. Each of these periods in the bitch lasts about two months. At their termination the uterus and the generative organs pass back to a condition of rest, and so the oestrous cycle is repeated. The complete cycle takes about six months in the bitch, there being typically two cycles and two oestrous periods in the year but there is a good deal of individual and racial variation.

If pregnancy takes place as a result of fertilization of the ova, discharged during oestrus, these segment and become attached to the inside wall (mucous membrane) of the uterus, which grows around each of them. The structure formed in this way is highly vascular and serves as the organ of nourishment for the developing embryos to which the ova give rise. (*See* VERTEBRATE EMBRYOLOGY.) This organ is the *placenta* and is characteristic of nearly all mammals. The embryos are attached to the placenta of the mother by the outer of a number of membranes, and vascular processes (*villi*) grow out from this membrane (the *chorion*) into the hypertrophied uterine mucous membrane now forming the maternal placenta. Thus a close connection is formed between the embryo and the mother and the placenta acts as an organ of respiration, supplying the developing young with oxygen brought thither in the maternal blood, and an organ of excretion, getting rid of carbon dioxide and the waste nitrogenous products, besides supplying the necessary nutriment. During pregnancy also the uterine muscles undergo a great hypertrophy, and are responsible for a great part of the increased weight which occurs in that organ. Thus, in the human subject, the virgin uterus weighs about 30 grams, whereas the same organ at the close of pregnancy, apart from the contained young, weighs 1,000 grams. It is through the rhythmical contraction of the uterine muscles that the young are expelled in parturition (the act of giving birth). The mammary glands undergo great development during pregnancy in preparation for the secretion of milk at its close.

If the ova discharged at ovulation are not fertilized during oestrus (as when coition does not occur) they die in the uterus and disintegrate. Nevertheless, in the bitch and many other mammals the uterus and mammary glands pass through growth-changes which, though not so pronounced, are similar in character to those during pregnancy. Thus, the mucous membrane becomes highly vascular and the glands greatly enlarge. The mammary glands also undergo marked development and towards the end of the period secrete milk. Even virgin bitches secrete milk freely about two months after the cessation of oestrus. At the end of this pseudo-pregnancy the generative system as a whole subsides into a condition of rest.

The ovarian changes (at any rate in the bitch) are also similar in both pregnancy and pseudo-pregnancy. The Graafian follicle, after parting with its ovum, becomes converted into the *corpus luteum* or "yellow body," so called on account of a pigmented fat (lutein) formed inside it. The yellow body is formed by the rapid hypertrophy of the cells surrounding the wall of the follicle; this is so great that the individual cells increase in size 16 or 20 times. This structure, which plays an important part during pregnancy, lasts throughout that period (and correspondingly during pseudo-pregnancy) and then undergoes degeneration.

In polyoestrous animals there is a succession of oestrous periods within a single breeding season, that is to say, that if coition does not take place at the first oestrus, or if for some other reason the ova discharged at ovulation are not fertilized, the animal, instead of experiencing a prolonged pseudo-pregnancy followed by an anoestrum (as with the bitch), undergoes a short period of apparent quiescence, called by Heape the dioestrum, and then "comes on heat" again. Thus with the sheep, the ewe, if she fails to become pregnant at her first oestrus, "comes back to the ram" (as the shepherds say) after about 15 days, and if she again fails, may experience a third oestrus after another 15 days, and so on for a succession of cycles until the breeding season is over or the ewe succeeds in becoming in-lamb. This short (or dioestrous) cycle in the sheep is therefore 15 days. The number of dioestrous cycles which the animal is capable of experiencing depends partly on the breed and partly on the environment, whether favourable or otherwise. Among sheep of all breeds there is a complete gradation between the monoestrous condition of certain wild varieties and the extreme of polyoestrum exhibited by certain merinos, in which there may be no anoestrum (even in the non-occurrence of pregnancy) but (in the absence of the ram) an unbroken succession of dioestrous cycles which last the whole year. Many wild animals (*e.g.*, rodents) are polyoestrous and the dioestrous cycle may last for only a few days.

In polyoestrous animals ovulation typically occurs during oestrus and is followed by the formation of the corpus luteum. The time of persistence of this structure varies according to whether or not pregnancy occurs. In the absence of pregnancy the corpus luteum persists for the duration of the dioestrum and then begins to degenerate as if to make way for the ripening of a fresh batch of follicles in the ovary and a new oestrous period. If, however, pregnancy takes place the corpus luteum continues in the ovary until parturition as in monoestrous animals. In reality, the dioestrum, instead of being a period of complete rest, is of the nature of a very abbreviated pseudo-pregnancy, and the uterus undergoes some growth changes in association with the presence of the corpus luteum in the ovary.

In man there is typically no anoestrum (except among the Esquimaux in winter) and the menstrual cycles, each lasting about a month, correspond to the dioestrous cycles of the polyoestrous lower mammal The actual menstrual phenomena probably represent the degenerative changes at the end of an abbreviated pseudo-pregnancy (or dioestrum) telescoped into the prooestrum of a new cycle. Ovulation takes place most commonly about the 18th day after the beginning of the menstrual flow but it may occur at other times, though rarely, in the week or ten days before the beginning of menstruation.

In some animals (rabbit, ferret) ovulation only takes place after coition. The actual process can be demonstrated in an anaesthetized rabbit whose ovaries have been exposed to view (Hammond). It is probable that in man also ovulation may sometimes require the additional stimulus set up by coition. In most domestic animals (bitch, sow, ewe, cow, mare) ovulation takes place spontaneously at or about the time of oestrus.

The Testis and Ovary as Organs of Internal Secretion.—It has been mentioned that the testis, besides producing the spermatozoa, is also an organ elaborating an internal secretion which is discharged into the blood. A similar statement may be made about the ovary. The evidence for these conclusions falls under three heads, (1) the effects of removing these organs (castration), (2) the effects of transplanting the testis or ovary into animals whose own gonads have previously been removed, and (3) the result of injecting tissue extracts prepared from testes or ovaries.

The general effect of castration in all vertebrate animals is to prevent the development of the secondary characters of sex, that is, of those characters which, while correlated with the sex in question, are not directly concerned with reproduction. This statement applies to ovariotomy or the extirpation of the ovaries

in the female as well as to castration in the male. It is essential, however, that this operation should be performed early in life to have its full effect. It not only ensures permanent sterility (whenever it is done) but if performed on the young stops the development of superficial sexual characters as well as the accessory reproductive organs (prostate gland, etc.). Thus, in man, castration prevents the growth of hair on the face and various parts of the body and arrests the enlargement of the larynx and the consequent deepening of the voice normally characteristic of puberty in the male. In stags castration inhibits the growth of the antlers and in those breeds of sheep which are horned in the male and hornless in the female it prevents development of the horns; moreover, the horn growth is arrested at any stage of development at which castration is performed. With fowls, castration is followed by an arrest of the development of the erectile structures about the head (comb, wattles, etc.). Castration has been practised on the domestic animals from the earliest times, for it improves the quality of the flesh and favours fattening in meat-producing animals and is conducive to a greater tractability in working animals since the disturbing effects of sexual desire no longer occur.

If the testes are removed from the normal position and grafted to an abnormal one (or if the testes of another male are transplanted immediately after castration), the organs exert their usual influence on the secondary sexual characters and accessory sexual glands, although their normal nerve connections have been severed. Since, then, the influence of transplanted organs cannot be through intermediation of the nervous system it would seem that it must operate through chemical substances passed into the blood and so into the general circulation. Thus, in experiments upon fowls the testes have been removed and broken up into pieces, which have attached themselves to different parts of the alimentary canal or the wall of the body cavity, and the birds have developed into typical cocks with comb, wattle, etc., male voice, and sexual and combative instincts. Furthermore, the experiments of Steinach and others have shown that the grafting of testes into females whose ovaries had been removed may cause the development of secondary male characters and bring about a partial or complete reversal of sex. There is some evidence that the grafting of additional testicular tissue into the aged may bring about a general rejuvenation, and that if a similar operation is done upon an immature or young animal it may promote an increase in growth and hastening of maturity (Steinach, Voronoff).

Ovariotomy leads to the suppression of the distinctly female characters. If done before puberty the uterus and mammary glands do not develop and the general bodily form tends towards a neutral condition not dissimilar to that of the castrated male. If performed after puberty ovariotomy is followed by cessation of the oestrous or menstrual cycles and the uterus undergoes atrophy in much the same way as occurs normally at the menopause (climacteric) or time of permanent cessation of reproductive activity (in women at from 45 to 50). If, however, the ovaries (or one of them) instead of being removed are grafted to an abnormal position such as the ventral wall of the body cavity or into a kidney the oestrous cycle is continued and the uterus remains normal. Since the ovary in such a position is without its normal nerve supply it is presumed that its influence on the organism is due to internal secretions passed into the circulation. The corpus luteum is also believed to be an organ of internal secretion serving the special function of secreting into the blood substances essential for maintaining the raised nutrition of the uterus during pregnancy and for the development of the mammary glands, for if this structure be removed surgically pregnancy cannot continue, the uterus lapses, and the mammary glands fail to develop. The corpus luteum also plays some part in controlling the short or dioestrous cycle, for so long as it is present in its integrity heat cannot occur, but if it is extirpated some days before a new oestrous period is normally due, the period occurs shortly after the operation of removal. Thus Hammond, by squeezing out the corpus luteum of a cow, has induced oestrus after nine days instead of the usual 19 to 21.

Fertility and Sterility.—The number of spermatozoa discharged in a normal ejaculation of human semen is estimated at 226,000,000, whereas the number of ova ejected at one ovulation is usually only one. For mammals generally the number of ova discharged is on an average only slightly more than the average number of young in a litter. It follows that the female rather than the male controls the size of the litter. (On the other hand, Sanders has shown for horses that a reduction in the number of spermatozoa may reduce the chances of the ovum being fertilized.) The sheep discharges one or two (sometimes three and rarely more) ova at oestrus, but by "flushing" the ewes, that is supplying them with extra or stimulating food before and during breeding, the number may be increased and consequently a higher proportion of lambs obtained. This is an example of the influence of favourable nutrition upon fertility. Too high feeding (resulting in adiposity), however, promotes atrophy of the ova in the ovary and so is conducive to sterility. There is evidence also that sterility may be due to the absence of certain essential accessory food substances or vitamins (*q.v.*) and that such a vitamin is present in green food (Evans). Degeneration of ova in the ovary may therefore be due to faulty nutrition of various kinds, but some degeneration is normal.

Sterility may result from coition at an inappropriate time, that is, at too long an interval before or after ovulation, for Hammond has shown in the rabbit that the ova are not capable of being fertilized for longer than four hours after their release from the ovary, and that the spermatozoa in the female passages do not retain their power of fertilization for more than two days. (In the male passage, where they are quiescent, they retain this power for 30 days.) It is probable that in many other mammals the duration of viability of the spermatozoa and ova is not widely different. In animals such as the mare, which has a prolonged oestrus (a week or more), sterile unions may well be due to this cause (Hammond).

Artificial insemination is sometimes successfully resorted to in cases where sterility has been due to an abnormal constriction of the os uteri or to the presence of an acid secretion in the vagina. The practice is to inject the semen directly into the os uteri, thus avoiding the constriction or escaping the action of the abnormal secretion. Walton has found that the semen of rabbits may be kept in a fertile condition in tubes outside the body at a medium temperature for more than five days and that after a journey by post from Cambridge to Edinburgh the spermatozoa contained therein could still successfully fertilize ova with normal pregnancy as a result.

Fertility, like other characters, is capable of being transmitted from one generation to another. Thus rams which were twin lambs may hand on the tendency to produce twins to the next generation of ewes, and by breeding from rams which were twins the fertility of a flock may be increased.

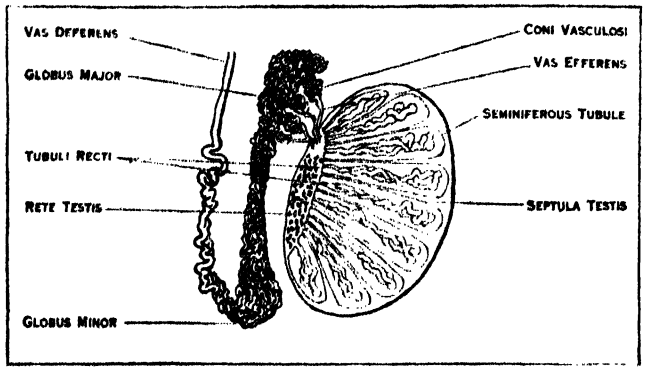
REPRODUCTIVE SYSTEM, ANATOMY OF. The reproductive system in some parts of its course shares structures with the urinary system (*q.v.*). In this article the following structures will be dealt with: In the male the testes, epididymis, vasa deferentia, vesiculae seminales, prostate, penis and urethra. In the female the ovaries, Fallopian tubes, uterus, vagina and vulva.



MALE REPRODUCTIVE ORGANS

The *testes* or *testicles* are the glands in which the male reproductive cells are formed. They lie, one on each side, in the scrotum surrounded by the tunica vaginalis (*see* COELOM AND SEROUS MEMBRANES). Each is oval, about one and a half inches long and has a strong fibrous coat (*tunica albuginea*), from which septa penetrate into the substance, dividing it into lobules in which the seminiferous tubes are coiled. It is estimated that the total length of these seminiferous tubes in the two glands is little short of a mile. (*See* fig. 1.)

Posteriorly, the fibrous sheath is thickened, and contains a

plexus of tubules (*rete testis*) (*see* fig. 1), into which the seminiferous tubes open. In this way the secretion of the gland is carried to its upper and back part, whence from fifteen to twenty small tubes (*vasa efferentia*) pass to the epididymis. Each of these is convoluted before opening (*conus vasculosus*).

Microscopically, the seminiferous tubules consist of a basement membrane surrounding several layers of epithelial cells,

FROM CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 1.—DIAGRAM SHOWING THE STRUCTURE OF THE TESTIS, AND EPIDIDYMIS

some of which are constantly being transformed into spermatozoa or male sexual cells.

The *epididymis* (*see* fig. 1) is a soft body lying behind the testis; it is enlarged above to form the *globus major* or head, while below is a lesser swelling, the *globus minor* or tail. The whole epididymis is made up of a convoluted tube about 20ft. long. Between the globus major and the testis two small vesicles (*hydatids of Morgagni*) are often found.

The *vas deferens* is the continuation of the tube of the epididymis and starts at the globus minor; it runs up on the inner (mesial) side of the epididymis to the external abdominal ring. On its way up it is joined by testicular arteries, veins, lymphatics and nerves to form the *spermatic cord*. After entering the external abdominal ring, these structures pass obliquely through the abdominal wall, lying in the inguinal canal for an inch and a half, until the internal abdominal ring is reached. Here they separate and the vas passes down the side of the pelvis and turns inward to meet its fellow at the back of the bladder, just above the prostate. The whole length of the vas is 12 to 18in. and it is remarkable for the thickness of its muscular walls, which gives it the feeling of a piece of whipcord when rolled between the finger and thumb.

A little above the globus major a few scattered tubules are found in children in front of the cord; these form the rudimentary structure known as the *organ of Giraldès* or *paradidymis*.

The *vesiculae seminales* are muscular sac-like diverticula, one on each side, from the vasa deferentia. They are about 2in. long and run outward behind the bladder and parallel to the upper margin of the prostate for some little distance, but usually turn upward near their blind extremity. When unravelled each is about 5in. long, sharply bent upon itself two or three times. Where the vesiculae join the ampullae of the vasa deferentia the *ejaculatory ducts* are formed; these are narrow and thin-walled, and run, side by side, through the prostate to open into the floor of the prostatic urethra.

The *prostate* is situated just below the bladder and traversed by the urethra; it is somewhat conical with the base upward in contact with the bladder. Vertically and transversely it measures about an inch and a quarter, antero-posteriorly it is only about three-quarters of an inch, though its size is liable to great variation. It is enclosed in a fibrous capsule from which it is separated by the *prostatic plexus of veins* anteriorly.

Microscopically, it consists of masses of long, slender, slightly branching glands, embedded in unstriped muscle and fibrous tissue; these glands open by delicate ducts (about twenty in number) into the prostatic urethra.

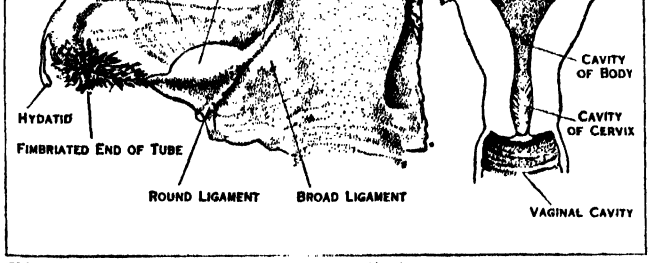
The *male urethra* begins at the bladder and runs through the prostate and perineum to the penis, which it traverses as far as the tip. It is divided into a prostatic, membranous and spongy part, and is altogether about 8 inches in length. The *prostatic urethra* is about an inch and a quarter long, and a longitudinal ridge is seen in its posterior wall (*verumontanum*), on each side of which the numerous ducts of the prostate open. Near the lower part of the verumontanum is a little pouch, the *utriculus masculinus*, about one-eighth of an inch deep, the opening of which is guarded by a delicate membranous circular fold, the *male hymen*. Close to the opening of the utriculus the ejaculatory ducts open into the urethra by very small apertures. The part of the urethra above the openings of these ducts really belongs to the urinary system only, though it is convenient to describe it here. After leaving the prostate the urethra runs more forward for about three-quarters of an inch, lying between the two layers of the triangular ligament, both of which it pierces. This is known as the *membranous urethra*, and is very narrow, being gripped by the compressor urethrae muscle.

The *spongy urethra* is that part which is enclosed in the penis after piercing the anterior layer of the triangular ligament. At first it lies in the substance of the bulb and, later, of the corpus spongiosum, while finally it passes through the glans. In the greater part of its course it is a transverse slit, but in traversing the glans it enlarges considerably to form the *fossa navicularis*, and here, in transverse section, it looks like an inverted T (⊥), then an inverted Y (⅄), and finally at its opening (external meatus) a vertical slit. Into the whole length of the urethra mucous glands (*glands of Littré*) open. As a rule the meatus is the narrowest part of the whole canal.

Opening into the spongy urethra where it passes through the bulb are the ducts of two small glands known as Cowper's glands, which lie on each side of the membranous urethra.

The *penis* is the intromittent organ of generation, and is made up of three cylinders of erectile tissue, covered by skin and subcutaneous tissue without fat. In a transverse section two of these cylinders (the *corpora cavernosa*) are above, side by side, while one, the *corpus spongiosum*, is below. At the root of the penis, the two corpora cavernosa diverge, become more and more fibrous in structure, and are attached on each side to the rami of the ischium, while the corpus spongiosum becomes more vascular and enlarges to form the bulb. The whole length of the corpus spongiosum is traversed by the urethra. The anterior part of the penis is formed by the *glans*, a bell-shaped structure, apparently continuous with the corpus spongiosum, and having the conical ends of the corpora cavernosa fitted into depressions on its posterior surface. On the dorsum of the penis the rim of the bell-shaped glans projects beyond the level of the corpora cavernosa (*corona glandis*). The skin of the penis forms a fold which covers the glans (*prepuce* or *foreskin*); when this is drawn back a median fold, the *frenulum praeputii*, is seen running to just below the meatus. After forming the prepuce the skin is reflected over the glans and here looks like mucous membrane. The structure of the corpora cavernosa consists of a strong fibrous coat, the *tunica albuginea*, from the deep surface of which trabeculae penetrate the interior and divide it into a number of spaces which are lined with endothelium and communicate with the veins. Between the two corpora cavernosa the sheath is not complete and, having a comb-like appearance, is known as the *septum pectinatum*. The structure of the corpus spongiosum and glans resembles that of the corpora cavernosa, but the trabeculae are finer and the network closer.

FEMALE REPRODUCTIVE ORGANS



The *ovary* is an organ which in shape and size somewhat resembles a large almond, though its appearance varies in different individuals, and at different times of life. It lies in the side wall of the pelvis and is attached to the uterus by the ligament of the ovary, while its anterior border has a short reflection of peritoneum (*mesovarium*), running forward to the broad ligament of the uterus. It is through this anterior border that the vessels and nerves enter and leave the gland.

Under the microscope the ovary is seen to be covered by a layer of cubical cells, continuous near the anterior border with

the cells of the peritoneum. Deep to these is the ovarian stroma and embedded in it are numerous nests of epithelial cells, the *Graafian follicles,* in various stages of development. During the childbearing period some of these will be nearing the ripe condition and then contain one large cell, the *ovum,* surrounded by a mass of small cells forming the *discus proligerus.* At one point this is continuous with a layer of cells (*stratum granulosum*) which lines the outer wall of the follicle, but elsewhere the two layers are separated by fluid, the *liquor folliculi.* When the follicle bursts, as it does in time, the ovum escapes on to the surface of the ovary. The substance of the ovary also contains cells which are believed to form the ovarian internal secretion.

The *Fallopian tubes* receive the ova and carry them to the uterus. That end of each which lies in front of the ovary has a number of fringes (*fimbriae*) hanging from it; one of the largest of these is the ovarian fimbria and is attached to the upper or tubal pole of the ovary. The small opening among the fimbriae by which the tube communicates with the peritoneal cavity is the *ostium abdominale,* and from this the lumen of the tube runs from four to four and a half inches, until it opens into the cavity of the uterus by an extremely small opening. In fig. 2 the Fallopian tube and ovary are pulled out from the uterus; this is not the position of the ovary in the living body, nor is it of the tube, the outer half of which lies folded on the front and inner surface of the ovary. The Fallopian tubes are made chiefly of unstriped muscle, the outer layer of which is longitudinal and the inner circular; deep to this are the submucous and mucous coats, the latter being lined with ciliated epithelium (*q.v.*) and thrown into longitudinal pleats. Superficially the tube is covered by peritoneum.

The *uterus* or *womb* is a pear-shaped, very thick-walled muscular bag, lying in the pelvis between the bladder and rectum. In the non-pregnant condition it is about three inches long and two in its broadest part, which is above. The upper half or body is somewhat triangular with its base upward, and has an anterior surface which is moderately flat, and a posterior convex. The lower half is the neck or cervix and is cylindrical; it projects into the anterior wall of the vagina, into the cavity of which it opens by the *os uteri externum.* This opening in a uterus which has never been pregnant is a narrow transverse slit, rarely a circular aperture, but in those uteri in which pregnancy has occurred the slit is much wider and its lips are thickened and gaping and often scarred. The interior of the body of the uterus shows

FROM CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 2.—(LEFT) THE UTERUS AND BROAD LIGAMENT SEEN FROM BEHIND: (RIGHT) DIAGRAMMATIC REPRESENTATION OF THE UTERINE CAVITY, OPENED UP FROM IN FRONT

a comparatively small triangular cavity (*see* fig. 6, B), the anterior and posterior walls of which are in contact. The base of the triangle is upward, and at each lateral angle one of the Fallopian tubes opens. The apex leads into the canal of the cervix, but between the two there is a slight constriction known as the *os uteri internum.* The canal of the cervix is about an inch long, and is spindle-shaped when looked at from in front; its anterior and posterior walls are in contact, and its lining mucous membrane is raised into a pattern which, from its likeness to a cypress twig, is called the *arbor vitae.* This arrangement is obliterated after the first pregnancy. On making a mesial vertical section of the uterus the cavity is seen as a mere slit which is bent about its middle to form an angle the opening of which is forward. A normal uterus is therefore bent forward on itself, or anteflexed. In addition to this, its long axis forms a marked angle with that of the vagina, so that the whole uterus is bent forward or anteverted. As a rule, in adults the uterus is more or less on one side of the mesial plane of the body. From each side of the uterus the peritoneum is reflected outward, as a two-layered sheet, to the side wall of the pelvis; this is the *broad ligament,* and between its layers lie several structures of importance. Above, there is the Fallopian tube, already described; below and in front is the round ligament; behind, the ovary projects backward, and just above this, when the broad ligament is stretched out as in fig. 2, are the epoöphoron and paroöphoron with the duct of Gärtner.

The *round ligament* is a cord of unstriped muscle which runs from the lateral angle of its own side of the uterus forward to the internal abdominal ring, and so through the inguinal canal to the upper part of the labium majus.

The *epoöphoron* or *parovarium* is a collection of short tubes which radiate from the upper border of the ovary when the broad ligament is pulled out as in fig. 2. It is best seen in very young children and represents the vasa efferentia in the male. Near the ovary the tubes are closed, but nearer the Fallopian tube they open into another tube which is nearly at right angles to them, and runs toward the uterus, though in the human subject it is generally lost before reaching that organ. It is known as the duct of Gärtner, and is the homologue of the male epididymis and vas deferens. Some of the outermost tubules of the epoöphoron are sometimes distended to form hydatids. Nearer the uterus than the epoöphoron a few scattered tubules (*paroöphoron*) are occasionally found which are looked upon as the homologue of the organ of Giraldès in the male.

The *vagina* is a dilatable muscular passage, lined with mucous membrane, which leads from the uterus to the external generative organs; its direction is, from the uterus, downward and forward, and its anterior and posterior walls are in contact, so that in a horizontal section it appears as a transverse slit. As the orifice is neared the slit becomes H-shaped. Owing to the fact that the neck of the uterus enters the vagina from in front, the anterior wall of that tube is only about 2½in., while the posterior is 3½. The mucous membrane is raised into a series of transverse folds or rugae, and between it and the muscular wall are plexuses of veins forming erectile tissue. The relation of the vagina to the peritoneum is noticed under COELOM AND SEROUS MEMBRANES.

The *vulva* or *pudendum* comprises all the female external generative organs, and consists of the mons Veneris, labia majora and minora, clitoris, urethral orifice, hymen, bulbs of the vestibule, and glands of Bartholin. The *mons Veneris* is the elevation in front of the pubic bones covered by hair in the adult. The *labia majora* are two folds of skin, containing fibro-fatty tissue and covered on their outer surfaces by hair, running down from the mons Veneris to within an inch of the anus and touching one another by their internal surfaces. They are the homologues of the scrotum in the male. The *labia minora* are two folds of skin containing no fat, which are usually hidden by the labia majora and above enclose the clitoris, they are of a pinkish colour and look like mucous membrane.

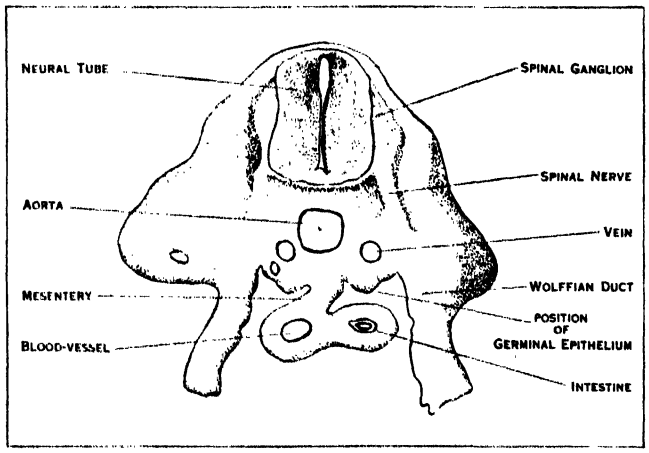
The *clitoris* is the representative of the penis, and consists of two corpora cavernosa which posteriorly diverge to form the crura clitoridis, and are attached to the ischium; the organ is about an inch and a half long, and ends anteriorly in a rudimentary glans which is covered by the junction of the labia minora; this junction forms the prepuce of the clitoris.

The *orifice of the urethra* is about an inch below the glans clitoridis and is slightly puckered.

The *hymen* is a fold of mucous membrane which surrounds the orifice of the vagina and is usually only seen in the virgin. As has been pointed out above, it is represented in the male by the fold at the opening of the uterus masculinus.

The *bulbs of the vestibule* are two masses of erectile tissue

situated one on each side of the vaginal orifice: above they are continued up to the clitoris; they represent the bulb and the corpus spongiosum of the male, split into two, and the fact that they are so divided accounts for the urethra failing to be enclosed in the clitoris as it is in the penis.



The *glands of Bartholin* are two oval bodies about half an inch long, lying on each side of the vagina close to its opening; they represent Cowper's glands in the male, and their ducts open by minute orifices between the hymen and the labia minora.

From the foregoing it will be seen that all the parts of the male external genital organs are represented in the female, though usually in a less developed condition, and that, owing to the orifice of the vagina, they retain their original bi-lateral form.

EMBRYOLOGY

The development of the reproductive organs is so closely interwoven with that of the urinary that some reference from this article to that on the URINARY SYSTEM is necessary. It will here be convenient to take up the development at the stage depicted in the accompanying figure (fig. 3), in which the genital ridge is seen on each side of the attachment of the mesentery; external to this, and forming another slight ridge of its own, is the Wolffian duct, while a little later the Müllerian duct is formed and lies ventral to the Wolffian. The early history of these ducts is indicated in the article on the URINARY SYSTEM. Until the fifth or sixth week the development of the genital ridge is very much the same in the two sexes, and consists of cords of cells growing from the epithelium-covered surface into the mesenchyme, which forms the interior of the ridge. In these cords are some large germ cells which are distinguishable at a very early stage of development. It must, of course, be understood that the germinal epithelium covering the ridge, and the mesenchyme inside it, are both derived from the mesoderm or middle layer of the embryo. About the fifth week of human embryonic life the tunica albuginea appears in the male, from which septa grow to divide the testis into lobules, while the epithelial cords form the seminiferous tubes, though these do not gain a lumen until just before puberty. From the adjacent mesonephros, or perhaps, coelomic epithelium, cords of cells grow into the attached part of the genital ridge, or testis, as it now is, and from these the rete testis is developed.

In the female the same growth of epithelial cords into the mesenchyme of the genital ridge takes place, but each one is

FROM CUNNINGHAM, "TEXT BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 3.—TRANSVERSE SECTION THROUGH A RAT EMBRYO SHOWING POSITION OF GERMINAL EPITHELIUM

distinguished by a bulging toward its middle, in which alone the large germ cells are found. Eventually this bulging part is broken up into a series of small portions, each of which contains one germ cell or ovum and gives rise to a Graafian follicle. Mesonephric cords appear as in the male; they do not enter the ovary, however, but form a transitory network (*rete ovarii*) in the mesovarium. As each genital gland enlarges it remains attached to the rest of the intermediate cell mass by a constricted fold of the coelomic membrane, known as the *mesorchium* in the male, and the *mesovarium* in the female. Lying dorsal to the genital ridge in the intermediate cell mass is the *mesonephros*, consisting of numerous tubules which open into the Wolffian duct. This at first is an important excretory organ, but during development becomes used for other purposes. In the male, as has been shown, it may form the rete testis, and certainly forms the vasa efferentia and globus major of the epididymis: in addition to these, some

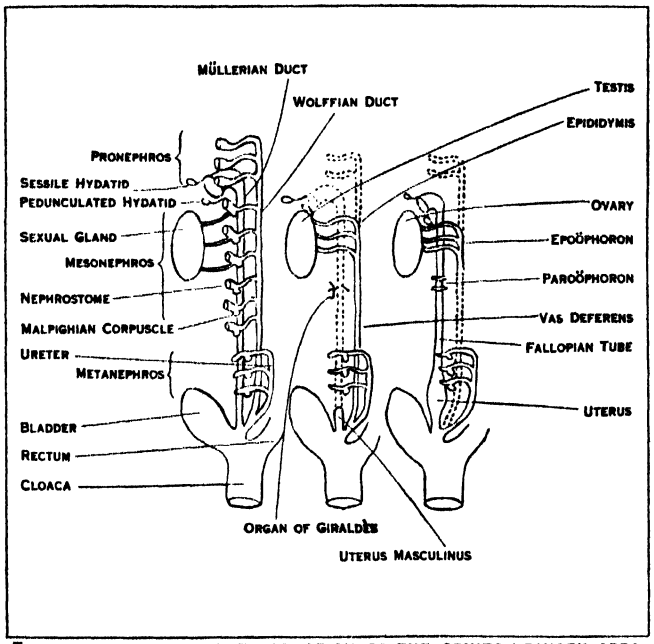


FIG. 4.—DIAGRAM OF THE FORMATION OF THE GENITO-URINARY APPARATUS (SUPPRESSED PARTS ARE DOTTED)

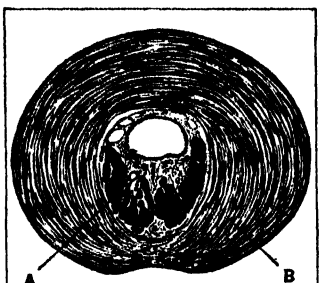

of its separate tubes probably account for the vas aberrans and the organ of Giraldès (*see* fig. 4). In the female the tubules of the epoöphoron represent the main part, while the paroöphoron, like the organ of Giraldès in the male, is probably formed from some separate tubes (*see* fig. 4).

The Wolffian duct, which, in the early embryo, carries the excretion of the mesonephros to the cloaca, forms eventually the body and tail of the epididymis, the vas deferens, and ejaculatory duct in the male, the vesicula seminalis being developed as a pouch in its course. In the female this duct is largely done away with, but remains as the collecting tube of the epoöphoron, and in some mammals as the duct of Gärtner, which runs down the side of the vagina to open into the vestibule.

The Müllerian duct, as it approaches the cloaca, joins its fellow of the opposite side, so that there is only one opening into the ventral cloacal wall. In the male the lower part only of it remains as the uterus masculinus (fig. 4), but in the female the Fallopian tubes, uterus, and probably the vagina, are all formed from it (fig. 4). In both sexes a small hydatid or vesicle is liable to be formed at the beginning of both the Wolffian and Müllerian duct (fig. 4); in the male these are close together in front of the globus major of the epididymis, and are known as the sessile and pedunculated hydatids of Morgagni. In the female there is a hydatid among the fimbriae of the Fallopian tube which of course is Müllerian and corresponds to the sessile hydatid in the male, while another is often found at the beginning of the collecting tube of the epoöphoron and is probably formed by a blocked mesonephric tubule. This is the pedunculated hydatid of the male. The development of the vagina, as Berry Hart (*Journ. Anat. and Phys.* xxxv. 330) has pointed out, is peculiar. Instead of the two Müllerian ducts joining to form the lumen of its lower third, as they do in the case of the uterus and its upper two-thirds, they become obliterated, and their place is taken by two solid cords of cells, which later become canalized and the septum between them is obliterated.

The common chamber, or cloaca, into which the alimentary, urinary and reproductive tubes open in the foetus, has the urinary bladder (the remains of the allantois) opening from its ventral wall (*see* PLACENTA and URINARY SYSTEM).

During development the alimentary or anal part of the cloaca is separated from the urogenital. According to F. Wood Jones, the anal part is completely shut off from the urogenital and ends in a blind pouch which grows toward the surface and meets a new ectodermal depression, the permanent anus, not being part of the original cloacal aperture, but a new perforation. This description is in harmony with the malformations occurring in this region.

FROM WALLACE, "PROSTATIC ENLARGEMENTS" (OXFORD MEDICAL PUBLICATIONS)

FIG. 5.—TRANSVERSE SECTION OF SHEEP'S PROSTATE; (A) PROSTATE GLAND, (B) STRIATED MUSCLE

The external generative organs have at first the same appearance in the two sexes and consist of a swelling, the genital eminence, in the ventral wall of the cloaca. This in the male becomes the penis and in the female the clitoris. Throughout the generative system the male organs depart most from the undifferentiated type and in the case of the genital eminence two folds grow together and enclose the urogenital passage, thus making the urethra perforate the penis, while in the female these two folds remain separate as the labia minora. Sometimes in the male the folds fail to unite completely and then there is an opening into the urethra on the under surface of the penis—a condition known as hypospadias.

In the undifferentiated condition the integument surrounding the genital opening is raised into a horseshoelike swelling with its convexity over the pubic symphysis and its concavity toward the anus; the lateral parts of this remain separate in the female and form the labia majora, but in the male they unite to form the scrotum. The median part forms the mons Veneris or mons Jovis.

It has been shown that the testis is formed in the loin region of the embryo close to the kidney, and it is only in the later months of foetal life that it changes this position for that of the scrotum. In the lower part of the genital ridge a fibro-muscular cord is formed which stretches from the lower part of the testis to the bottom of the scrotum; it is known as the gubernaculum testis, and by its means the testis is directed into the scrotum. Before the testis descends, a pouch of peritoneum called the processus vaginalis passes down in front of the gubernaculum through the opening in the abdominal wall, which afterwards becomes the inguinal canal, into the scrotum, and behind this the testis descends, carrying with it the mesonephros and mesonephric duct. These, as has already been pointed out, form the epididymis and vas deferens. At the sixth month the testis lies opposite the abdominal ring, and at the eighth reaches the bottom of the scrotum and invaginates the processus vaginalis from behind. Soon after birth the communication between that part of the processus vaginalis which now surrounds the testis and the general cavity of the peritoneum disappears, and the part which remains forms the tunica vaginalis. Sometimes the testis fails to pass beyond the inguinal canal, and the term "cryptorchism" is used for such cases.

In the female the ovary undergoes a descent like that of the testis, but it is less marked since the gubernaculum becomes attached to the Müllerian duct where that duct joins its fellow to form the uterus; hence the ovary does not descend lower than the level of the top of the uterus, and the part of the gubernaculum running between it and the uterus remains as the ligament of the ovary, while the part running from the uterus to the labium is the round ligament. In rare cases the ovary may be drawn into the labium just as the testis is drawn into the scrotum.

COMPARATIVE ANATOMY

In the Urochorda, the class to which Salpa, Pyrosoma and the sea squirts (Ascidians) belong, male and female generative glands (*gonads*) are present in the same individual; they are therefore hermaphrodite.

In the Acrania (Amphioxus) there are some twenty-six pairs of gonads arranged segmentally along the side of the pharynx and intestine and bulging into the atrium. Between them and the atrial wall, however, is a rudimentary remnant of the coelom, through which the spermatozoa or ova (for the sexes are distinct) burst into the atrial cavity. There are no genital ducts.

In the Cyclostomata (lampreys and hags) only one median gonad is found, and its contents (spermatozoa or ova) burst into the coelom and then pass through the genital pores into the urogenital sinus and so to the exterior. It is probable that the single gonad is accounted for by the fact that its fellow has been suppressed.

In the Elasmobranchs or cartilaginous fishes there are usually two testes or two ovaries, though in the dogfish one of the latter is suppressed. From each testis, which in fish is popularly known, as the soft roe, vasa efferentia lead into the mesonephros, and the semen is conducted down the vas deferens or mesonephric duct into the urogenital sinus, into which also the ureters open. Sometimes one or more thin-walled diverticula—the sperm sacs—open close to the aperture of the vas deferens. In the female the ova are large, on account of the quantity of yolk, and they burst into the coelom, from which they pass into the large Müllerian ducts or oviducts. In the oviparous forms, such as the common dogfish (Scyllium), there is an oviducal gland which secretes a horny case for the egg after it is fertilized, and these cases have various shapes in different species. Some of the Elasmobranchs, *e.g.*, the spiny dogfish (Acanthias), are viviparous, and in these the lower part of the oviduct is enlarged and acts as a uterus. In male elasmobranchs the anterior part of the Müllerian duct persists. Paired intromittent organs (claspers) are developed on the pelvic fins of the males; these conduct the semen into the cloaca of the female.

In the teleostean and ganoid fishes (Teleostomi) the nephridial ducts are not always used as genital ducts, but special coelomic ducts are formed (*see* COELOM AND SEROUS MEMBRANES).

In the Dipnoi or mudfish long coiled Müllerian ducts are present, but the testes either pour their secretion directly into the coelom or, as in Protopterus, have ducts which are probably coelomic in origin.

In both the Teleostomi and Dipnoi the testes and ovaries are paired.

True hermaphroditism is known among fishes, the hag (Myxine) and the sea perch (Serranus) being examples. In many others it occurs as an abnormality.

In the Amphibia both ovaries and testes are symmetrical. In the snakelike forms which are found in the order Gymnophiona the testes are a series of separate lobules extending for a long distance, one behind the other, and joined by a connecting duct from which vasa efferentia pass into the Malpighian capsules of the kidneys, and so the sperm is conducted to the mesonephric duct, which acts both as vas deferens and ureter. The Müllerian ducts or oviducts are long and often coiled in Amphibia, and usually open separately into the cloaca. There is no penis, but in certain forms, especially the Gymnophiona, the cloaca is protrusible in the male and acts as an intromittent organ. Corpora adiposa or fat bodies are present in all Amphibians, and probably nourish the sexual cells during the hibernating period.

In Reptilia two testes and ovaries are developed, though they are often asymmetrical in position. In Lizards the vas deferens and ureter open into the cloaca by a common orifice; as they do in the human embryo. In these animals there are two penes, which can be protruded and retracted through the vent; but in the higher reptiles (Chelonia and Crocodilia) there is a single median penis rising from the ventral wall of the cloaca, composed of erectile tissue and deeply grooved on its dorsal surface for the passage of the sperm.

In birds the right ovary and oviduct degenerates, and the left alone is functional. In the male the ureter and vas deferens open separately into the cloaca, and in the Ratitae (ostriches) and

Anseres (ducks and geese) a well-developed penis is present in the male. In the ostrich this is fibrous, and bifurcated at its base, suggesting the crura penis of higher forms.

Among the Mammalia the Monotremata (Ornithorhynchus and Echidna) have bird-like affinities. The left ovary is larger than the right, and the oviducts open separately into the cloaca and do not fuse to form a uterus. The testes retain their abdominal position; and the vasa deferentia open into the base of the penis, which lies in a separate sheath in the ventral wall of the cloaca, and shows an advance on that of the reptiles and birds in that the groove is now converted into a complete tunnel. In the female there is a well-developed clitoris, having the same relations as the penis.

In the marsupials the cloaca is very short, and the vagina and rectum open separately into it. The two uteri open separately and three vaginae are formed, two lateral and one median. The two lateral join together below to form a single median lower vagina, and it is by means of these that the spermatozoa pass up into the oviducts. The upper median vagina at first does not open into the lower one, but during parturition a communication is established which in some animals remains permanent (*see* J. P. Hill, *Proc. Linn. Soc. N.S. Wales*, 1899 and 1900). From the marsupials upward the ovarian end of the Fallopian tube has the characteristic fimbriated appearance as in human anatomy.

In some mammals, such as the sow and the cow, the Wolffian duct is persistent in the female and runs along the side of the vagina as the duct of Gärtner. It is possible that the lateral vaginae of the marsupials are of Wolffian origin.

In marsupials the testes descend into the scrotum, which lies in these animals in front of instead of behind the penis. In some mammals, such as the elephant, they never reach the scrotum at all; while in others, *e.g.*, many rodents, they can be drawn up into the abdomen or lowered into the scrotum. The subject of the descent of the testicles is treated by H. Klaatsche, "Ueber den Descensus testiculorum," *Morph. Jahrb.*, Bd. xvi.

The prostate is met with in its most simple form in marsupials, in which it is a mere thickening of the mucous membrane of the urethra; in the sheep it forms a bilateral elongated mass of gland tissue lying behind the urethra and surrounded by a well-developed layer of striped muscle. In the sloth it is said to be altogether absent, while in many of the insectivores and rodents it consists of many lobes which usually show a bilateral arrangement. The vesiculae seminales are usually present in higher mammals, and sometimes, as in the hedgehog, are very large, though they are absent in the Carnivora. Cowper's glands are usually present and functional throughout life. The uterus masculinus is also usually present, but there is grave doubt whether the large organ called by this name in the rabbit should not rather be regarded as homologous with part of the vesiculae seminales. The penis shows many diversities of arrangement; above the marsupials its two crura obtain an attachment to the ischium. In many mammals it is quite hidden by the skin in the flaccid condition, and its external orifice may range from the perineum in the marsupials to the middle of the ventral wall of the abdomen in the ruminants. In the Marsupialia, Rodentia, Chiroptera, Carnivora and some Primates an os penis is developed in connection with the corpora cavernosa.

The clitoris is present in all mammals; sometimes, as in the female hyena, it is very large, and at others, as in the lemur, it is perforated by the urethra.

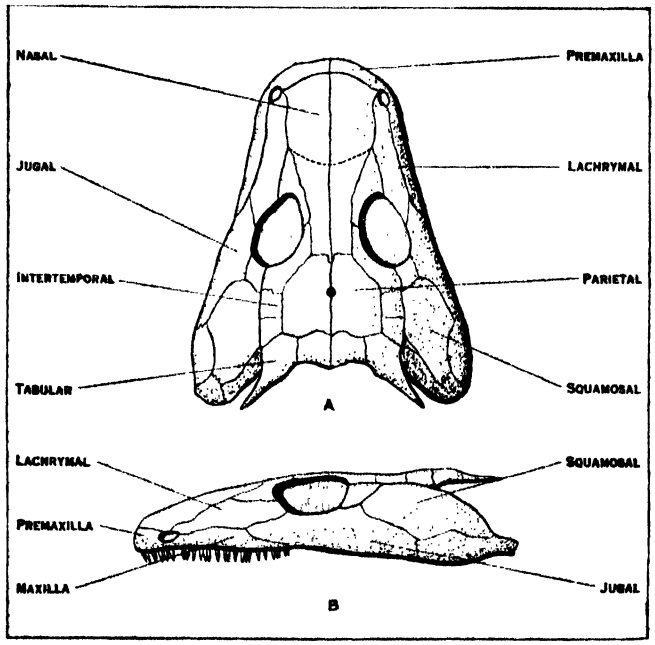
REPTILES (*Reptilia*) is the name given to a class of vertebrates which hold a position in the animal kingdom intermediate between the amphibians and the birds, and the mammals. The group arose, perhaps in Lower Carboniferous times, from the Labyrinthodont Amphibia, and was already varied at the end of the Carboniferous. During Permian times the class branched out into many orders, one of which included the ancestors of the Mammalia, whilst from another the birds, crocodiles, Sphenodon, and perhaps the lizards and snakes arose. The tortoises are the descendants of another early group. In a recent survey by Nopcsa, it is pointed out that, of the 125 families into which he divides the reptiles, only 18 are represented by living forms, whilst of the 19 orders only four are extant. The modern forms fall into the orders Crocodilia, including the crocodiles and alligators; the Squamata, the lizards and snakes; the Rhynchocephalia, represented only by the Tuatera lizard of New Zealand, and the Chelonia, the tortoises and turtles. These living forms are characterized as follows:

(1.) The animal breathes air by lungs.



(2.) The body temperature is variable.

(3.) The skin is covered with horny scales formed by the epidermis.

(4.) Fertilization is internal, and an egg, consisting of a yolk surrounded by albumen and contained in a shell, is usually laid and hatched by the heat of the sun or of decaying vegetation. In some cases reptiles are viviparous.

(5.) In the brain the cerebral hemispheres are comparatively small. Their roof tends to become thinned and may be almost membranous. There is a well-developed hypopallium which becomes assimilated to the corpus striatum, losing the original stratification of the neurones. The mid-brain is relatively large and its roof forms a pair of large optic lobes.

(6.) The olfactory organ has its surface increased by a simple turbinal or concha, and there is a well-developed Jacobson's organ.

FROM PHILOSOPHICAL TRANSACTIONS OF THE ROYAL SOCIETY

FIG. 1.—SKULL OF THE EMBOLOMEROUS AMPHIBIAN PALAEOGYRINUS. (A) FROM ABOVE. (B) FROM THE LEFT SIDE

The posterior nares may be immediately below the external nostrils or may be carried back to the hinder end of the head.

The eyes are usually present, but may be hidden in burrowing forms. The retina normally contains both rods and cones, but may consist exclusively of either type. There is a pecten in the form of a folded sheet projecting into the vitreous humour.

The internal ear shows a more marked separation of *sacculus* and *utriculus* than obtains in Amphibia, a lagena always occurs and is associated with a perilymphatic duct, in some cases so as to form a rudimentary cochlea. The tympanic cavity lies high up and the tympanic membrane is either superficial or lies at the end of a short external auditory meatus. The membrane is con-

nected to that closing the *fenestra ovalis* by a straight rod, whose inner end, the columella, is bony, whilst the outer half, the extra-columella, is often four-rayed, a short dorsal process being connected to the end of the paroccipital process and a ventral process often continued into the hyoid.

(7.) There is a well-developed tongue capable of free movement. The mid-gut has the usual structure; there is a cloaca and an urinary bladder of allantoic origin. The lungs are more elaborate than those of Amphibia and less than those of mammals.

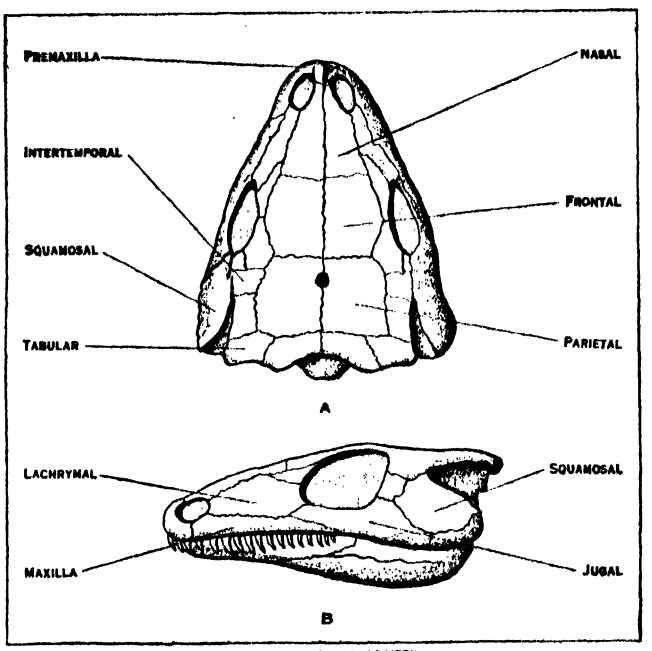
(8.) The heart is three- or four-chambered, there being two auricles and a ventricle more or less completely divided into two. There is no bulbus; three arteries arise from the ventricle; of these one is the right systemic, another the pulmonary, whilst the third is the left systemic and both carotids. The posterior cardinals have both almost disappeared as such, the post-caval vein returning most of the blood from the posterior part of the animal to the heart. There is a coronary circulation.

(9.) The functional kidney in the adult is a metanephros discharging by a ureter into the cloaca. The ovary is often single and the egg always large. The oviduct is provided with glands which secrete albumen and a shell. A copulatory organ is usually present in the male, but is variable in structure.

(10.) The pre-sacral part of the vertebral column is usually less clearly divided into regions than in mammals and birds. There are two sacral vertebrae and a longer or shorter series of caudals. The atlas consists of a pair of neural arches, a single inter centrum and a centrum which forms an odontoid, though it may not be fused to the axis. There is sometimes a pro-atlas. The vertebra of the rest of the column always consists of a neural arch and a centrum with inter-centra forming chevron bones in the tail. Small inter-centra may be present throughout the column. Ribs are usually present on all vertebrae except the posterior caudals; they may be single or double headed. A true sternum is usually present, connected to some of the dorsal ribs by sternal ribs.

The neural cranium is generally incompletely ossified, a good deal of the lateral walls anteriorly being membranous. It is often movably connected to the dermal bones of the skull roof and palate. There is a single occipital condyle, mainly basi-occipital but with contributions from the ex-occipital. A supra-occipital is present and articulates with the parietals. The inner ear lies within the opisthotic, usually fused with the ex-occipital, the pro-otic and the supra-occipital. An ossification in front of the pro-otic, in the side wall of the cranium, is absent in only two orders. There is an ossified basi-sphenoid, but the unossified pre-sphenoid is usually underlain by a para-sphenoid.

The dermal bones of the skull form a roof, which may be very incomplete or, indeed, absent, over the masticatory muscles, whilst the orbit is surrounded by a ring of bones which are continuous with the maxillae and nasals which enclose the anterior end of the head. In the palate the pterygoids are always large bones articulating with the basi-sphenoid and extending back to the quadrate. Pre-vomers and palatines are always present and ectopterygoids usually so. In many forms an epipterygoid is ossified. The lower jaw is complex, it articulates with the quadrate by an articular bone of endochondral origin, and at least five membrane bones contribute to its structure.



Fore and hind limbs are usually present, but either or both may be absent. The shoulder girdle consists of a pair of scapulae and "coracoids," both contributing to the glenoid cavity. There are generally clavicles and an inter-clavicle. The hand and foot are primitively pentadactyl, the fourth digit being the longest.

(11.) Segmentation of the egg is incomplete (meroblastic). No primitive streak is formed and a rudimentary archenteron with both roof and floor may be established. There is an amnion and an allantois, membranes developed for the protection, nutrition and respiration of the embryo.

Amphibian Ancestry.—The Amphibia, which were the ancestors of the reptiles, spent the greater part of their life in water, probably crawling on to land only to pass from one pool to another. They laid small eggs, which were fertilized after they had passed out from the body of the mother. These eggs developed into an aquatic larva which breathed by means of gills; subsequently, when this larva had reached a relatively large size, the gills were absorbed and the animal became dependent on the air for the main bulk of its oxygen. An aquatic animal may have, and in the case of the Amphibia did have, a soft skin which can only remain healthy if it be kept moist. Living Amphibia secure this condition by pouring out mucus and water from glands in their skin, which is therefore slimy. An animal which adopts this method has great difficulty in roaming far from water, the possibility of dying from desiccation being always present. Thus one of the first changes necessary to make an effectively terrestrial animal from an amphibian is to alter the character of its skin in such a way that it becomes water-tight, and has a dry outer surface. Such a change in a vertebrate is most readily achieved by thickening the epidermis and laying down keratin in its outer layers; continuation of this process leads to the formation of the horny scales of reptiles, which are made by localized patches of skin exceptionally active in the production of keratin. As such a skin does not require to be kept moist, glands are very poorly developed in the skin of reptiles.

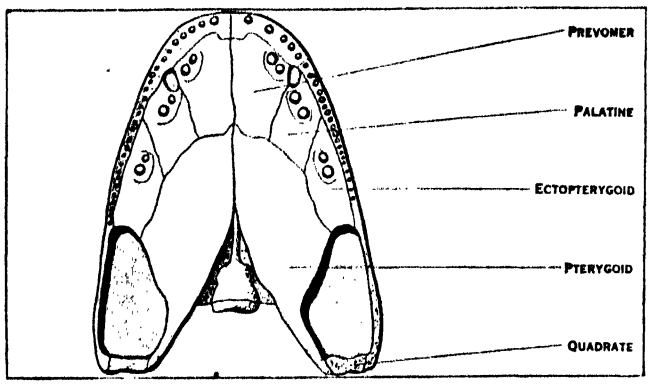
During the transition from water to air the sense organs necessarily undergo great modifications. The olfactory organ, which had become adapted to the relatively large amounts of odorous substances which could come to it in solution in water, had to be made capable of recognizing the much smaller amounts brought to it as vapour through the air. In the intervening stage of the Amphibia the nose becomes double, one part of it, Jacobson's organ, functioning in water, the rest in air. When the reptiles became completely terrestrial, Jacobson's organ took on the new function of smelling the material lying in the mouth, and the rest of the organ became the normal organ of smell.

The eye, adapted for focussing objects under water, has to be so

FROM PHILOSOPHICAL TRANSACTIONS OF THE ROYAL SOCIETY

FIG. 2.—SKULL OF THE COTYOSAUR SEYMOURIA; (A) FROM ABOVE, (B) LEFT SIDE

changed in its proportions as to see its surroundings through air.



That part of the ear whose function is to determine the position of the animal with respect to gravity and to recognize changes in position, can remain unaltered, but the lagena, which, with its associated structures, the columella, middle ear and tympanic membrane, is concerned with hearing in the ordinary sense, necessarily undergoes changes on account of the very different specific gravity of the mediums, water or air, through which sound waves come to it.

Aquatic Amphibia have, in common with fish, a special sense,

whose organ is the lateral line, which is concerned with the recognition of movements in water; with the transition to land this sense is entirely lost.

Any animal living in water is so nearly floating that the proportion of its weight which has to be supported by the limbs is extremely small. As soon as it comes out of water practically the whole of its weight falls on the legs. Thus the skeleton and musculature necessarily become more powerful.

The most serious changes, however, are those in the mode of reproduction. An amphibian which lays its eggs in the water can fertilize them there, but a terrestrial animal can only lay an egg

FROM PHILOSOPHICAL TRANSACTIONS OF THE ROYAL SOCIETY

FIG. 3.—PALATE OF THE EMBOLOMEROUS AMPHIBIAN, BAPHETES

if it be included in a shell which will protect it from mechanical injury and, a matter of more importance, from drying up. Such a shell cannot be perforated by a spermatozoan, so that fertilization must take place within the body of the mother before the shell is formed. The uro-genital organs of both sexes have to be so modified as to allow this to take place, and the oviduct of the female must be provided with the glands that are necessary for the formation of the shell.

The amphibian egg may be comparatively small; it only needs to contain a food supply sufficient to maintain the developing embryo to a stage when it hatches as a small larva capable of feeding on the abundant food present in the water in which the egg was laid. The animal, which hatches from an egg laid on land, must make its appearance at a stage in development when it can maintain itself under conditions similar to those in which its parents live. The time taken in reaching such a stage of development is considerable, and the egg included in its shell has no opportunity of obtaining food or water from outside. Thus, when laid, the egg must contain everything necessary for the development of the embryo up to the time of hatching.

The reptile ovum, the yolk of the egg, contains the great bulk of the food materials, whilst the albumen, the white which surrounds it, is mainly a water store. The egg-shell is porous and transmits gases. The character of the development of the large egg is necessarily modified by its bulk, much of the yolk remaining undivided into cells until it is absorbed and converted into part of the animal's own tissues. Special embryonic membranes, the amnion and allantois, are produced during the development for the protection of the embryo and for its nutrition and respiration, the allantois serving also as a reservoir for the nitrogenous waste products produced by its metabolism.

The great majority of these changes, including all those which are of the greatest importance, cannot be determined from fossil material, and we are driven back for the discrimination between fossil reptiles and fossil amphibians to the use of technical points mainly of little functional importance to the animal. The break between the Amphibia and Reptilia was regarded by Huxley and other early workers as the most important in the vertebrate phylum; such contrasted terms as Ichthyopsida and Sauropsida, Anamniota and Amniota emphasize its importance. None the less we now know an animal, Seymouria, from the lowest Permian of Texas, which is regarded by one group of students as an amphibian and by another as a reptile. As the osteology of this animal is very completely known, the doubt which exists as to its systematic position illustrates vividly the completeness with which the gap between these two divisions has been bridged.

Seymouria is a small animal about 2 ft. in length, with a comparatively small head, no visible neck, a somewhat stumpy body, and a short tail. The limbs were very muscular, but short. The hands and feet were placed far away from the middle line, and the stride was exceedingly small Each limb has five digits.

The skull of Seymouria consists of two parts, which could have easily been separated from one another. These are the brain-case, made of bones which have replaced the cartilage which existed in the embryonic skull, and a superficial coating covering the whole outer surface of the head (except for the nostrils, orbits and pineal foramen), and the roof of the mouth, made of bones which have developed in the lower layers of the skin. The pattern formed by these dermal bones is identical with that which is found in the more primitive Labyrinthodont Amphibia, and is important, because from it the structure of the corresponding parts of the skulls of all other reptiles can be derived, by a process of reduction. The palate of Seymouria is, in essence, identical with that of an Embolomerous Labyrinthodont. The brain case, however, differs somewhat from those of the Amphibia. For example, the single occipital condyle is convex instead of being concave, and there is a large fenestra ovalis leading into the ear which does not exist in the Embolomeri. There are also variations in other details of the structure of the otic region. In the lower jaw, Seymouria is identical with an amphibian, but the vertebral column is very different.

In the amphibian the first vertebra articulates with the condyle by a disc-shaped inter-centrum followed by a disc-shaped centrum, of the same character as those which succeed it. In Seymouria the rounded condyle articulates below with a concavity on an inter-centrum which represents only the lower half of that of the amphibian, and with facets carried on the lower ends of the two halves of the neural arch. The centrum of the atlas is a curious trefoil-shaped bone which fits in between the three elements which articulate with the condyle; this arrangement is completely reptilian. The structure of a vertebra from the middle of the back of Seymouria is quite peculiar. There is a small cylindrical centrum separated from the next by an intercentrum having the shape of half a disc. The neural arch is enormously heavy, it articulates with the centrum alone and the pre- and post-zygopotheses are produced laterally as masses of bone which overhang the much smaller centrum. The articulating faces are quite flat and placed horizontally, so that the back, although free to move from side to side, must have been extremely stiff dorso-ventrally.

Vertebrae of this type are known in no amphibian, but in a less exaggerated form occur in many of the more primitive reptiles. It is reasonable to believe that they were evolved as a clumsy method of giving that stiffness to the back which is necessary to an animal which, living in air, has to support the whole of its weight. The ribs of Seymouria do not differ essentially from those of some Labyrinthodonts. The limb girdles and limbs are of the amphibian pattern except in one or two details, *e.g.*, the occurrence of an ent-epi-condylar foramen piercing the humerus, and the number of the phalanges, which is two, three, four, five, three, the characteristic reptilian number.

Thus it is possible to be in doubt whether an extinct animal whose skeleton is completely known is an amphibian or a reptile, the break between the two being completely bridged so far as the skeleton is concerned. From a skeleton similar to that of Seymouria it is possible to derive those of all later reptiles, and in this way, by sorting out separate evolutionary lines to establish a classification which may express not only differences of structure existing between the animals contained in it, but something of their phylogenetic relationships.

Evolutionary Development.—The reptiles, as a whole, with a few doubtful exceptions, divide into two great branches, the mammal-like reptiles and the rest. The differences between the members of these two groups are to be found mainly in the structure of the brain case and the back of the skull. In all the

mammal-like reptiles the inner ear lies in the lower part of the side wall of the brain-case, the brain extending far above it, whilst in all other reptiles the ear extends throughout the whole of the side wall of the cranium and is not exceeded in height by the brain. In Seymouria the tympanic membrane is stretched across a notch on the outer surface at the back of the skull; in the mammal-like reptiles this notch is destroyed, so that the occipital surface of the skull is flat and the tympanic membrane, if it exists at all, lies ventrally in the neighbourhood of the hinder end of the lower jaw, to one of whose elements it is attached. In the remaining reptiles the tympanic or otic notch is preserved, bounded above by a special process of the squamosal or tabular bone, and by the free distal extremity of the paroccipital. The tympanic membrane, when present, lies high up on the side of the head, far removed from the lower jaw. In the mammal-like reptiles the stapes is attached directly to the quadrate bone, whilst in the others it is continued by an extra columella which is inserted into the tympanic membrane.

It is customary to recognize a primitive group of reptiles, the Cotylosauria, which includes the most primitive members of each division of the reptiles. The animals included in it agree with Seymouria in that the dermal bones of the outer surface of the skull form a continuous sheet, perforated only by the nostrils, orbits and pineal foramen. This group is restricted to Permian and Triassic time, and its members thus possess very primitive limbs and limb-girdles. They are usually devoid of a neck, the shoulder-girdle lying immediately behind the head. The back is short and the vertebrae of which it is composed have very massive neural arches which articulate with one another by horizontal surfaces. The centra are perforated and transmit a continuous notochord. There is usually a series of intercentra throughout the column. The shoulder girdle has three bony elements, the scapula, procoracoid and coracoid in each side of the cartilage girdle; all of them contribute to the glenoid cavity. Cleithra are often present, and clavicles and large inter-clavicles are universal. The fore leg is short and massive, the humerus projecting out at right angles to the animal's body and lying in a plane parallel to the ground. It can only be moved backwards and forwards, and is incapable of rotation. The elbow joint is flexible, so that the fore arm has much freedom of movement. The hand has five fingers, the number of the phalanges being 2, 3, 4, 5, 3, in the digits from 1 to 5. The pelvis consists of an ilium, pubis and ischium on each side, these bones meeting one another in continuous sutures, so that the whole structure is "plate-like." The hind limb projects out laterally and the knee was relatively inflexible; it could be stretched out straight, but, in many cases, could not be closed even to a right angle. The foot has five toes with a digital formula 2, 3, 4, 5, 4.

This super-order can be divided into three sub-groups, as follows:—(A.) Seymouria morpha, primitive forms represented by three genera, Solenodonsaurus, from the Upper Carboniferous of Czechoslovakia; Seymouria, from the basal Permian of Texas, and Kotlassia, from the Upper Permian of Russia, which may not properly belong to the group.

These animals possess skulls which very greatly resemble those of the Embolomerous Amphibia. (*See* AMPHIBIA.) These skulls have a narrow otic notch differing from that of all other reptiles; the neural cranium is peculiar in that the powerful paroccipital processes which arise from the sides of the brain case extend outwards and upwards to support the tabular bones. The basioccipital, together with the exoccipitals, form a rounded condyle. There are well marked basisphenoidal tubera and the basipterygoid processes of the basisphenoid are short, and in Seymouria support the pterygoid, not directly, but through the intervention of the epipterygoid. The parasphenoid is short and narrow. The palate is almost completely roofed with bone, there being small palatal nostrils and sub-temporal fossae in addition to a very conspicuous inter-pterygoid vacuity. The palatine bears a large tusk, the marginal teeth in the upper jaw form a uniform unbroken series and exhibit an indefinite replacement. The lower jaw is built up from nine bones, dentary, splenial, post splenial, angular, sur-angular on the outer surface, the series of three coronoids between the prearticular and dentary, and an articular bone which, unlike that of all contemporary Amphibia, is not a mere part of the sur-angular. With this exception, the jaw is identical with that of a Labyrinthodont.

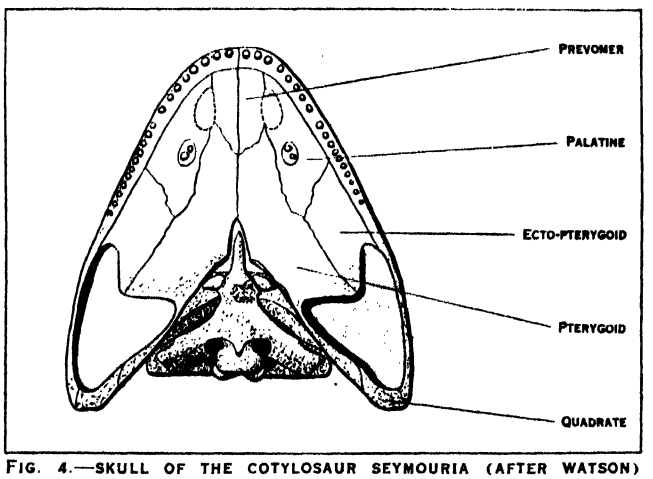
The vertebral column is massive, there is no distinction of neck, trunk, and lumbar region, all the vertebrae from the atlas back to the sacrum bearing two-headed ribs; there is one sacral vertebra. In the shoulder girdle a coracoid is absent, the lower part of the primary structure being ossified entirely as a pre-coracoid. The glenoid cavity has the characteristic screw-shaped form of the early Tetrapod. The humerus is an extraordinary bone, nearly as wide as it is long, whilst the fore arm is short. The hand is short and broad, the five fingers ending in small claws.

The pelvis is plate-like, the pubes and ischia being exceptionally large elements; the femur, short, broad and unusually massive, exactly resembles that of contemporary Amphibia. The fibula is widened distally, and the tarsus is remarkable amongst reptiles in possessing three bones in its proximal row, the intermedium being still separate from the tibiale. The foot is five toed, with the normal formula.

The mammal-like members of the Cotylosauria belong to the group (B.) Captorhinomorpha. This group includes a considerable number of reptiles, all of Lower Permian age, which vary a good deal in their general structure. The most typical are Captorhinus and its descendant, Labidosaurus. These animals are comparatively small, with no neck, rather long bodies and not excessively long tails. They had a straddling gait, the ventral surface touching the ground and the feet being placed well away from the side of the body. The head is pointed, the face in front of the eyes narrow, whilst the temporal region was wide. The skull is completely roofed and there is no trace of an otic notch, the head having a square cut appearance posteriorly. The brain case seems to be high, and is loosely connected with the rest of the skull by the summit of the supraoccipital and the ends of the paroccipital process. The stapes is very massive and extends from the fenestra ovalis, which is placed below the level of the brain, to the quadrate to which it is attached.

The lower jaw differs from that of Seymouria by a lateral compression of its hinder half, and by the reduction of the coronoids to one.

The vertebral column is characterized by the massiveness of the neural arches and the obsolescence of the neural spines. The



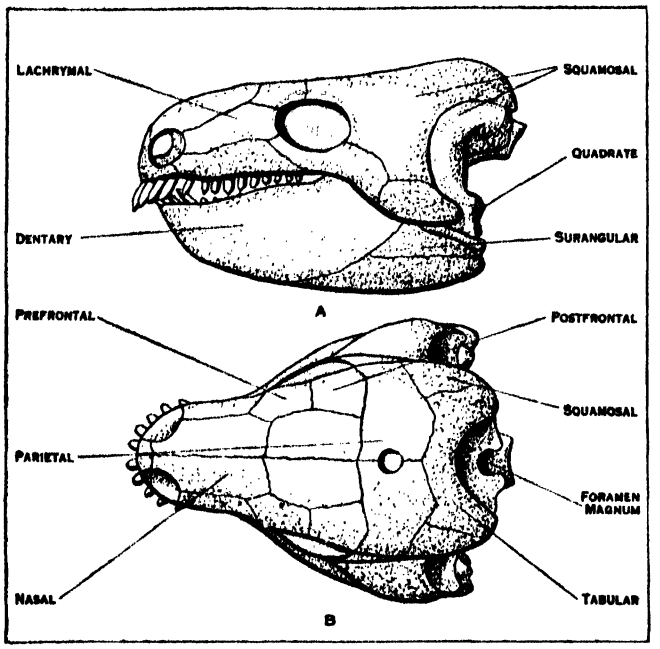


FIG. 4.—SKULL OF THE COTYLOSAUR SEYMOURIA (AFTER WATSON)

centra are small and perforated, the intercentra much reduced. All the ribs are single-headed. The remainder of the skeleton does not differ materially from that of Seymouria, which has been described above.

The earliest and most primitive members of the group of mammal-like reptiles belong to the order (C.) Pelycosauria. The most primitive members of this group, such as Varanosaurus and Mycterosaurus are small, rather slender animals, with elongated pointed heads. They had no visible neck, the shoulder girdle being placed behind the skull. The body was long and the

tail even longer. Their skulls differ from those of the Captorhinomorpha most obviously in that the dermal roof is no longer complete, but is perforated by a large lateral vacuity which is bounded by the jugal, postorbital and squamosal bones. This opening serves to give room for the thickening of the masticatory muscles, which necessarily occurs when they are shortened so as to close the mouth.

Another important difference is that the supraoccipital bone becomes so widened that, with the overlying interparietal and tabular, it forms a plate on the hinder surface of the skull, which reduces the post-temporal fossae to very small proportions.

FROM WILLISTON, "OSTEOLOGY OF REPTILES" (HARVARD UNIVERSITY PRESS)

FIG. 5.—SKULL OF THE CALYLOSAUR, DIADECTES; (A) LEFT SIDE WITH LOWER JAW, (B) FROM ABOVE

The only important changes in the post cranial skeleton are that the neural arches become light and narrow, the neural spines high, and the articulation faces of the zygapophyses are obliquely placed.

From such animals a series of short evolutionary lines arose, which led to the development of some extraordinary forms in which the neural spines from the head to the root of the tail become immensely elongated, and, in some cases, provided with lateral processes like the yard-arm of a ship. These animals, Dimetrodon and Naosaurus, must have been of grotesque appearance, one with a huge head with great piercing teeth, the other with a very small head with crushing dentition, each with a crest, as high as its own length from head to the root of the tail. Animals so specialized naturally had only a short range in time, they only occur in Lower Permian rocks, but the latter ranged from Czechoslovakia to Texas.

More conservative members of the group gave rise to a number of reptilian orders whose remains have been found in the Middle and Upper Permian rocks of Europe and South Africa, and in the Trias of South Africa, Asia and North America. The most important of these orders, the Theriodontia, included the ancestors of the mammals, and its members exhibit a series of stages which seem to bridge the structural gap between a Pelycosaur and a mammal very completely.

Some of these changes are illustrated by a comparison of the skulls of Scymnognathus and Cynognathus.

The skull of Scymnognathus, a Gorgonopsid, differs from that of a primitive Pelycosaur in that in it the whole head is flattened, the temporal vacuity, instead of facing laterally, is directed upward and is greatly increased in size; this change implies that the muscles which close the mouth had changed, an originally rather simple mass splitting up into pterygoidal, temporal and masseter muscles. In order to give room for this powerful development the side of the roof of the skull, formed by the jugal postorbital and squamosal, is bowed out, with the result that the quadrate and quadrato-jugal, being fixed in position by their articulation with the lower jaw, become detached from the side of the head and remain inserted in a depression on the front face of the squamosal, within the temporal vacuity. At the same time they are somewhat reduced in size.

The enlarged masticatory muscles require a more extensive area of attachment on the lower jaw, to provide which the upper and hinder end of the dentary becomes free and grows upward. At the same time, the hinder half of the jaw, composed of the surangular, angular, articular and prearticular bones, become converted into a thin sheet by a lateral compression, and the lower border of the angular is notched, a special lamina of the bone being reflected over the outer surface of its posterior part. To this reflected lamina the lower edge of the tympanic membrane seems to have been attached.

The palate, though it still has the posterior nares placed far forward, is advanced because it is very much vaulted, owing to the downgrowth of the maxillae on each side of it. Posteriorly, the pterygoids, with a parasphenoid held between them, form a narrow girder which connects the basisphenoid with the anterior part of the palate.

The stapes still articulates with the quadrate. The brain case is incompletely ossified in front of the point of exit of the fifth cranial nerve. The branches of that nerve pass on each side of the rod-like epipterygoid, and the cerebral hemispheres are enclosed in a single ossification homologous with the sphenethenoid of a frog.

Cynognathus has advanced beyond Scymnognathus in that the face has become deeper and more rounded, and the nostrils larger. The temporal vacuity has enlarged so that it is bounded above by the parietal, and this bone is drawn up into a deep sagittal crest which allows of longer temporal muscles. The quadrate and quadrato-jugal have become greatly reduced in size, but retain their position and function.

The coronoid process of the dentary has increased enormously, and now overlaps the rest of the lower jaw so greatly that it has nearly, but not quite, acquired an independent articulation on the squamosal.

The hinder part of the lower jaw, though still retaining all its constituent bones, has become so small that it seems inadequate to resist the very great stresses to which it might be subjected during feeding. The reflected lamina of the angular is still present in the form of a slender downturned process.

The palate has changed greatly, the original roof of the median area is still present in part, but it is concealed from view by a secondary palate exactly like that of a mammal, which is formed by ingrowths from the maxillae and palatines. By this change the posterior nares are driven so far backward that they open behind the cheek teeth, and the animal became capable of breathing whilst the mouth was full of food undergoing mastication. The ectopterygoid is greatly reduced, and the posterior part of the pterygoid, the quadrate ramus, has vanished altogether, its place being taken by a process which grows backward from the root of the epipterygoid.

The side walls of the brain case have become bony by a widening of the upper end of the epipterygoid, now recognizable as the homologue of the mammalian alisphenoid. This arrangement involves the inclusion in the cranial cavity of a space, the cavum epiptericum, which in most other reptiles lies outside the cranium. By a continuation of changes in the same direction as those which converted a Gorgonopsid such as Scymnognathus into the Cynodont Cynognathus, a primitive mammalian structure is easily reached.

The face changes little, a disappearance of the internarial processes throws the bony nostrils into one, the prefrontal and postorbital disappear, and the orbit becomes confluent with the temporal fossa.

Further growth of the dentary leads to the development of a new temporo-mandibular joint between that bone and the squa-

mosal, and the quadrate and hinder part of the jaw, freed from any function in connection with the jaw, become available as auditory ossicles. The stapes persists, little changed, the quadrate, further reduced in size, becomes the incus. The articular is the malleus, and the prearticular its processus folianus. The angular, to which the tympanic membrane has been attached for a very long period, becomes the tympanic, and the surangular disappears.

This account of the origin of the mammalian auditory ossicles is confirmed by the mode in which those bones develop in every mammal; indeed, all marsupials are still born in a stage in which the lower jaw still moves on the old reptilian joint between the incus and malleus, and the musculus tensor tympani still functions as a jaw muscle.

The palate of Cynognathus requires very few modifications to become typically mammalian. The already minute ectopterygoid vanishes, the great flanges of the pterygoids, which exist to ensure the accurate closure of the mouth, become unnecessary when the new temporo-mandibular joint is established, and vanish, and the posterior ramus of the alisphenoid becomes the tympanic process.

The skull of Scymnognathus is connected to the complex atlas by a single condyle composed of the basi and exoccipitals, that of Cynognathus has a mammal-like pair of exoccipital condyles.

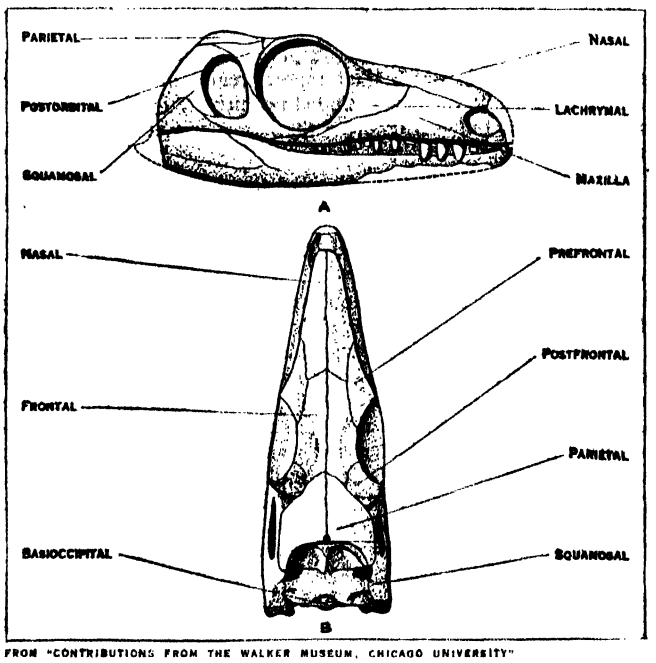
More serious modifications have to be made in the ear region and brain case. The opisthotic and pro-otic of Cynognathus house only part of the inner ear, the summit of that organ lying in the supraoccipital. In mammals, the whole lies in a single bone, the periotic. The mammalian periotic is a much smaller bone than the pro- and opisthotics of a cynodont, and, unlike them, it is comparatively unimportant as a buttress for the squamosal. None the less, it is not impossible to homologize the different regions of the two sets of structures.

The post-cranial skeleton of Cynodonts shows a similar resemblance to that of mammals, some of the more important features of the evolution being discussed in the section *Locomotion* of this article. Thus we know in considerable detail the evolutionary stages which lie between the structure of an embolomerous amphibian and that of a mammal. Unfortunately, we can trace no such ancestry for the birds. We are certain that they sprang from a group of reptiles very remote from the mammal stock, but we are still faced by a considerable gap.

Classification.—The classification of reptiles is necessarily based on skeletal characters, and is still in a state of flux. The existing divergences of view are not very important; they relate to the phylogenetic position of a few orders, and do not seriously affect the main outline.

Class Reptilia.—Tetrapodous vertebrates, which breathe air throughout their life. The body temperature is variable. The heart possesses a sinus venosus, two auricles and a ventricle incompletely or completely divided into two; there is no conus arteriosus. Both systemic arches persist. The red blood corpuscles are nucleated, oval and biconvex. The kidney is a metanephros, and there is an allantoic bladder, in most forms. There is a cloaca, which in living reptiles is divided into a series of regions. The skin is either naked or covered with scales, never with feathers or hair. It includes very few glands, always placed in special situations, and not generally distributed. The skeleton is ossified. The skull comprises a cranium, of cartilage bones, and an extensive series of bones, which, dermal in origin, sink in and become membrane bones in the later forms. The occipital condyle is single or double. The lower jaw articulates with a quadrate bone and is built up of a number of bones. There is a rod-like columella auris. The vertebrae consist mainly of centra and neural arches, intercentra, when present, being small. Ribs occur on all precaudal vertebrae, those in the thoracic region joining to form a sternum in the mid-ventral line.

The pectoral girdle, when fully developed, includes at least a scapula and precoracoid, clavicles and an interclavicle. The pelvic girdle, except in one or two cases, articulates with two or more sacral ribs. The limbs are primitively pentadactyle and the phalangeal formula 2, 3, 4, 5, 3 or 4.



Fertilization is internal, the eggs are large and yolk laden, usually laid, when they are surrounded by a coat of albumen and a shell which is often calcified. Cleavage is meroblastic, a primitive streak is not formed, the embryo is surrounded by an amnion and an allantois is developed.

Super-order. Cotylosauria. Archaic reptiles in which the temporal region of the skull is completely covered by a continuous roof of dermal bones. Stapes either articulating with the quadrate or ending in a tympanic notch. Lower jaw usually with more than one coronoid. Presacral vertebrae (except in Pantylus) with very heavy neural arches with horizontal zygapophysial articular faces. Ribs one or two headed. No ossified sternum. Abdominal ribs sometimes present as fine bony rods. Shoulder girdle with scapula and precoracoid at least, a coracoid usually present in addition. Cleithra usually, clavicles and an interclavicle always present. Humerus with (usually) a screw-shaped head, short and with widely expanded extremities. Pelvis, plate-like, the suture between the pubis and ischium extending from the acetabulum to the middle line.

Order 1. Seymouriamorpha. Cotylosaurs in which the skull greatly resembles in all external features that of the Embolomerous Labyrinthodonts, the dermal bones are sculptured and the otic notch extends far forward below the tabular and supratemporal, so that the quadrate slopes backward. Stapes ending in the otic notch. Fenestra ovalis low down on the cranium, below the level of the base of the brain. Intercentra present and very large, ribs one or two headed. Only one sacral vertebra. Shoulder girdle without coracoid or cleithrum, limbs primitive.

Upper Carboniferous to Upper Permian. Families, *Seymouriidae, Kotlassiidae.*

Order 2. Captorhinomorpha. Cotylosaurs in which the otic notch has been obliterated by a movement backward of the upper end of the quadrate. Dermosupraoccipitals and tabulars, when present, restricted to the occipital surface. Stapes articulating

FROM "CONTRIBUTIONS FROM THE WALKER MUSEUM, CHICAGO UNIVERSITY"

FIG. 6.—SKULL OF PELYIOSAUR MYCTEROSAURUS: (A) RIGHT SIDE WITH LOWER JAW, (B) SKULL FROM ABOVE

distally with the quadrate. Brain case behind the incisura prooticum short and high, fenestra ovalis ventrally situated. Intercentra usually present. One or two sacral vertebrae. Shoulder girdle with both precoracoid and coracoid. Cleithrum present or absent. Limbs primitive, though sometimes slender.

Lower Permian. Families *Captorhinidae, Pantylidae, Limnoscelidae.*

Order 3. Diadectomorpha. Cotylosaurs in which the otic notch is enlarged by a movement forward of the lower end of the quadrate, dermosupra occipitals and tabulars when present on the

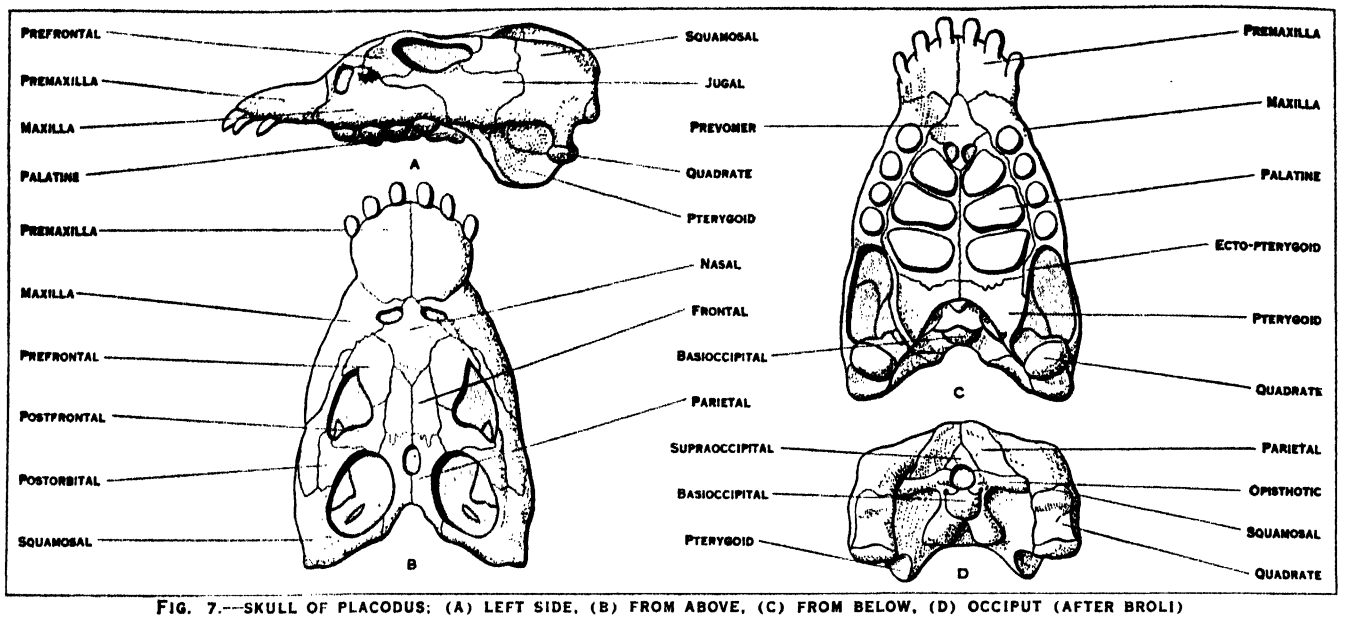


FIG. 7.—SKULL OF PLACODUS: (A) LEFT SIDE, (B) FROM ABOVE, (C) FROM BELOW, (D) OCCIPUT (AFTER BROILI)

upper surface of the skull, the latter overhanging the otic notch. Stapes terminating freely in the otic notch. Brain case long, fenestra ovalis placed at about the middle of its height. Intercentra usually present. Two to four sacral vertebrae. Shoulder girdle with a scapula alone or with three cartilage bones. Cleithrum usually present. Humerus always with expanded ends but often of advanced structure. Ilium sometimes backwardly directed.

Lower Permian to Middle Trias. Families: *Diadectidae, Pariasauridae, Procoelophonidae.*

Super-order Theromorpha (or *Anomodontia*). Mammal-like reptiles. Reptiles in which the temporal region of the skull is perforated by a single vacuity, bounded primitively by the postorbital and squamosal, but enlarging so that the parietal and jugal also enter its borders. Cranium short and high behind the incisura prooticum, fenestra ovalis below the level of the base of the brain. Stapes articulating with the quadrate. The lower jaw, and especially its hinder end, laterally compressed, the angular in all except, perhaps, the most primitive forms, with a notch in its lower border.

A pro-atlas present, the neural arch of the atlas usually a pair of bones, which, with the intercentrum, rest on the anterior end of a trefoil-shaped odontoid. Vertebrae with slender neural arches with oblique articular faces, centra notochordal or deeply amphicoelous. Intercentra usually present, at any rate in the cervical region, ribs always two-headed anteriorly, usually single-headed posteriorly. An ossified sternum sometimes present, abdominal ribs present as slender rods in primitive forms. Pectoral girdle with scapula, precoracoid and coracoid in all forms (except one, Varanops), clavicle with expanded lower end, and interclavicle a wide flat sheet. Cleithra usually present, but small. Pelvis very variable, plate-like in primitive forms, with an obturator foramen in later types. Ilium, directed forwards, vertically, or backward. Two to seven sacral vertebrae. Limbs exhibiting all stages of advance from primitive cotylosaur-like organs to a pro-mammalian condition. Digital formula primitively 2, 3, 4, 5, 3 or 4 reduced to 2, 3, 3, 3, 3 in later forms.

Order 1. Pelycosauria. Primitive Theromorpha in which the pterygoids articulate with the basipterygoid processes of the basisphenoid by a movable joint. The quadrate is relatively large and the quadrato-jugal forms part of the lateral surface of the skull. The shoulder girdle has a screw-shaped glenoid cavity shared by the scapula, coracoid and precoracoid, and the limbs are primitive. The pelvis is plate-like.

Upper Carboniferous and Lower Permian. Families: *Poliosauridae, Aphiacodontidae, Sphenacodontidae, Edaphosauridae, Caseidae, Bolosauridae, Palaeohatteriidae.*

Order 2. Deinocephalia. Theromorpha in which the pterygoids are attached to the basisphenoid by an immovable joint. The basioccipital and basisphenoid are produced downward below the occipital condyle as a thick sheet of bone. The quadrate is unreduced and the quadrato-jugal is on the lateral surface. The shoulder girdle in early forms has the glenoid cavity borne only to a very slight extent on the precoracoid, but it is screw-shaped; in later forms this structure disappears and the glenoid cavity is restricted to the scapula and coracoid. The limbs are of modernized type. The pelvis is plate-like, the ilium being attached to four sacral ribs.

Middle Permian. Families: *Tapinocephalidae, Titanosuchidae.*

Order 3. Dromosauria. Small Theromorpha in which the facial region of the skull is very short, the temporal fossa is bounded above by the postorbital and squamosal and the zygomatic arch; below it is reduced to a narrow rod so that the quadrate and quadrato-jugal project below it. Shoulder girdle with the glenoid cavity on the scapula and coracoid, precoracoid large. No cleithra. Pelvis plate-like. Limbs very long and slender, digital formula 2, 3, 3, 3, 3.

Upper Permian. One family only.

Order 4. Dicynodontia (or *Anomodontia*). Theromorpha in which the preorbital part of the skull is very short, whilst the temporal vacuity is greatly enlarged. The latter is bounded alone by the postorbital and squamosal. The quadrate and quadrato-jugal are reduced, and rest in a recess in the front face of the lower end of the T-shaped squamosal, which is widely expanded laterally so as to form a sheet in the plane of the occipital surface. The pterygoids are rigidly fixed to the basisphenoid, and are not produced into transverse flanges. The premaxillae are fused and toothless, the maxillae may have a large canine or a series of small cheek teeth, or both, or be toothless. A horny beak like that of a tortoise was always present. The articular of the lower jaw always has the unique feature of a convex articular surface. Intercentra are absent except in the atlas and axis. The tail is short. The glenoid cavity is entirely, or almost entirely, restricted to the scapula and to the coracoid. There is an acromium on the scapula which also shows the beginnings of a mammal-like scapular spine.

There is an obturator foramen in the pelvis. The limbs are short and powerful, the trunk wide, and the digital formula 2, 3, 3, 3, 3.

Upper Permian to Middle Trias. Division into families not yet carried out.

Order 5. Theriodontia. Theromorpha in which there is a differentiation of the dentition into incisors, canine and cheek teeth. The face is usually long, the temporal fossa, short in primitive forms,

elongated in the more advanced types, the parietal entering into its border.

Quadrate and quadrato-jugal, fused, much reduced and carried in a recess on the front face of the squamosal.

Pterygoids forming great transverse flanges, behind which they suddenly contract to form a narrow girder extending back to the basisphenoid. Palate at first with the large posterior nares placed anteriorly, becoming vaulted, the air passage being finally cut off from that for the food by a secondary palate. The dentary, always extending above the surangular, in a free coronoid process. Limbs and their girdles variable.

Sub-order 1. Gorgonopsia. Primitive Theriodonts, with the postorbital and squamosal meeting above the temporal fossa. Single occipital condyle: No sub-orbital vacuities. No secondary palate. Scapula without acromion, plate-like pelvis, digital formula (of hand) 2, 3, 4, 5, 3.

Upper Permian.

Sub-order 2. Cynodontia. Advanced Theriodonts, with the parietal entering the temporal fossa. No sub-orbital vacuities. A secondary palate. Pair of exoccipital condyles. Scapula with acromion. Pelvis with an obturator foramen. Limbs modernized, digital formula 2, 3, 3, 3, 3.

Top of the Permian and Lower Trias.

Sub-order 3. Therocephalia. Primitive Theriodonts with large temporal vacuities into whose border the parietal always enters. Large sub-orbital vacuities. No secondary palate or vaulting of the mid line of the anterior part of the palate. Single occipital condyle.

Upper Permian.

Sub-order 4. Bauriamorpha. Advanced Theriodonts, with the parietal forming part of the temporal fossa. Large sub-orbital vacuities, a secondary palate. Single occipital condyle.

Lower to Upper Trias.

Order 6. Thalattosauria. A group of marine reptiles, still incompletely known, but perhaps allied to the Pelycosauria. If so interpreted they may be defined by the following characters:—Skull with a very elongated face formed by the maxillae and premaxillae, nostrils dorsal and immediately in front of the large orbit, nasals small. The large temporal fossa is entirely lateral and is bounded above by the postorbital and squamosal. Quadrate large. A supratemporal present. Parietals short and wide. Vertebrae with biconcave centra which are short cylinders, ribs single-headed. Scapula and coracoid incompletely ossified. Humerus with expanded ends and a twisted shaft. Radius and ulna short flattened bones.

Upper Trias.

Super-order Archosauria (Diaptosauria). Reptiles in which the temporal region of the skull is perforated by two vacuities, the upper of these, the supratemporal fossa is bounded by the parietal, supratemporal, squamosal and postorbital the lower, the infratemporal fossa lies between the postorbital squamosal, quadrato-jugal and jugal bones.

The brain, at any rate in the later forms, is completely enclosed by bone, a pair of latero-sphenoids surrounding the cerebral hemispheres and stretching back to have a suture with the pro-otic. The epipterygoid forms no part of the wall of the cranial cavity. The fenestra ovalis lies half way up the wall of the brain case. There is always a distinct neck, often of eight vertebrae.

The pectoral girdle contains a scapula and precoracoid on each side, the true coracoid never appearing. Cleithra are never present. The sternum usually ossifies from a pair of centres. The limbs are never of the primitive Cotylosaurin character, and are often very highly modified. The digital formula is 2, 3, 4, 5, 4 or 3.

Order 1. Thecodontia. Primitive Archosauria in which a supratemporal, tabular and interparietal may be present in the skull. A preorbital vacuity may be present or absent. The ribs may have one or two heads and a sternum if ossified is paired.

Clavicles and an interclavicle are always present, the pelvis is plate-like, and there are only two sacral vertebrae.

Upper Permian to Upper Trias. Families: *Eosuchuidae, Phytosauridae, Pseudosuchidae, Erythrosuchidae, Erpetosuchidae* and others not yet defined.

This order is, in a sense, artificial, it includes the ancestors, for the greater part unknown, of the remainder of the orders of Archosauria, and in addition contains a number of animals which belong to short-lived unsuccessful side branches.

Order 2. Crocodilia. Archosaurs usually of medium or large size, and adapted more or less completely to an aquatic habit. The skull is characterized most clearly by the fact that the quadrate is very large, and lies at a very low angle with the horizontal. The wedge-shaped otic cavity so formed is closed behind by a downgrowth of the squamosal, which, with the overlapping "exoccipital" reaches the quadrate. The tympanic membrane lies some distance below the outer surface, and the external auditory meatus can be closed by a muscular flap. The elongated face is chiefly formed by the maxillae, the external nostrils, usually confluent in the bony skull lying quite anteriorly. There is always a secondary palate, the choanae lying posteriorly between the palatines or pterygoids. The vertebrae are amphiplatean or procoelous, the ribs double-headed throughout the presacral part of the column, the dorsal ribs articulating entirely with the neural arch. The coracoid is elongated, clavicles are absent; and the sternum is unossified. The ilium is a small bone supported by two sacral ribs, and the pubis is excluded from the acetabulum.

The hand is five-fingered, the foot has the fifth toe reduced to a stump of its metatarsal.

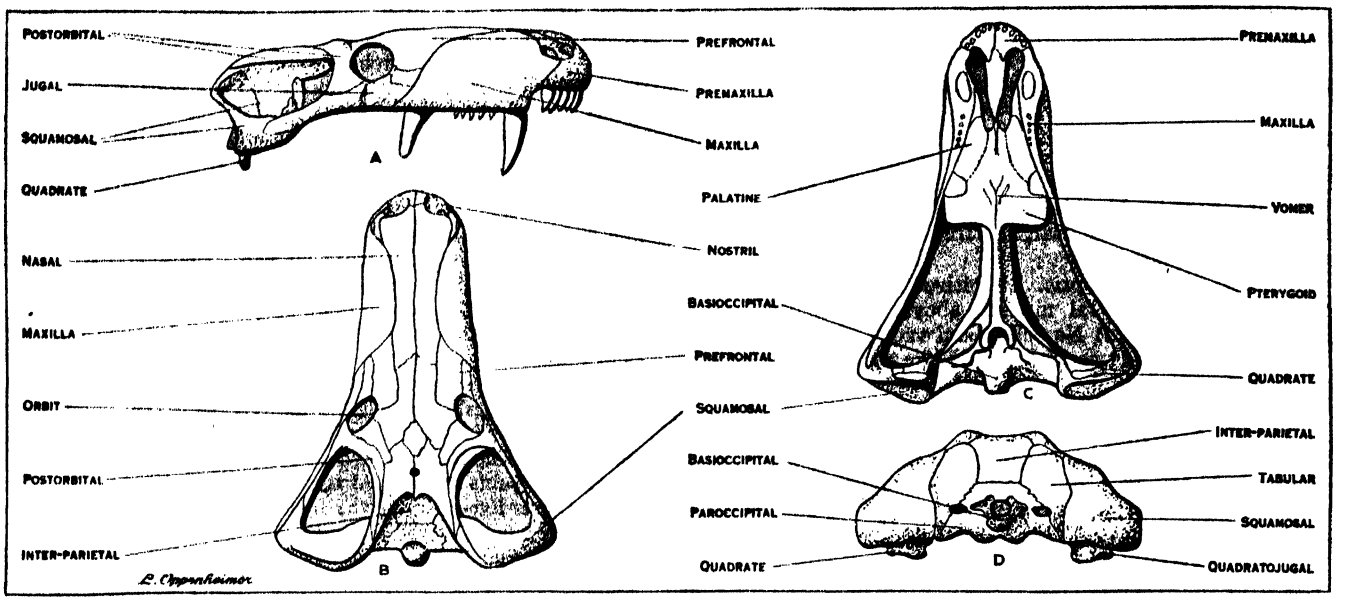
Lower Jurassic (Upper Trias) to Recent. Families *Teleosauriidae, Metriorhynihidae, Dyrosauridae, Goniopholidae, Libycosuchidae, Pholidosauridae, Stomatosuchidae, Gavialidae, Crocodilidae.*

It is not improbable that the Crocodilia sprang from the family *Erpetosuchidae* of the order Thecodontia.

Order 3. Saurischia (Deinosauria parts) Archosauria, with a well-developed preorbital vacuity. The neck is sharply marked off from the trunk. The presacral ribs are two-headed, and the dorsal ribs articulate only with the neural arch. Clavicle and interclavicle are lacking, the coracoid is short. There are three or more sacral vertebrae. The pubis and ischia form diverging rods, primitively the pelvis is plate-like, but the bones separate from one another in later forms. The acetabulum is perforat. The fore limb is shorter than the hind, and the femur moves in a plane parallel to the animal's length. The body is thus held well above the ground, and the animal is often bipedal.

Sub-order Theropoda. Carnivorous Saurischia, in which the dentition consists of a single series of the codont, laterally compressed teeth in the premaxillae and maxillae. The cervical vertebrae may be opisthocoelus. The fore limb is often very much smaller than the hind, and the animals are usually bipedal. The hand tends to be reduced to the first three fingers, which are provided with powerful claws, and the foot becomes functionally tridactyl and symmetrical about the third toe.

Middle Trias to Upper Cretaceous.



Families: *Hallopidae, Podokosauridae, Coeluridae, Compsognathidae, Ornithomimidae, Plateosauridae, Zanclodontidae, Anchisauridae, Megalosauridae, Spinosauridae.*

Sub-order Sauropoda. Herbivorous Saurischia, usually of gigantic size. The skull is extremely small, and the dentition feeble. The cervical and many or all the dorsal vertebrae opisthocoelic, Accessory articulating faces are developed in the neural arch of the dorsal vertebrae. The dorsal centra are excavated laterally, so that they may be reduced to mere shells of bones.

The animals are quadripedal, and walk on the ends of the metapodials, both feet are five toed, but some of the digits have a reduced number of phalanges and most lack claws.

Middle Jurassic to Upper Cretaceous. Families: *Cetrosauridae, Allantosauridae, Camarosauridae, Diplodocidae, Titanosuchidae.*

Order 4. Ornithischia (Deinosauria pars). Archosauria of herbivorous diet. The preorbital fossa is usually small or absent, the nostrils very large. The quadrate, unless secondarily fixed, is movable, a spherical head on its upper extremity resting in a cup in the squamosal. Premaxillae usually toothless, and covered with a horny beak, which opposes a similar structure carried by a special predentary bone in the lower jaw. Posterior end of the dentary raised into an upstanding coronoid process. The pubis bifid, a prepubic process stretching forward along the belly, and a posterior part passing downward and backward parallel to the

BY COURTESY OF THE ZOOLOGICAL SOCIETY OF LONDON

FIG. 8.—SKULL OF THE GORGONOPSID REPTILE, SCYMMOGNATHUS
A. Right side, B. from above, C. from below, D. occiput

ischium. Ilium elongated anteroposteriorly. Acetabulam perforate. Fore leg shorter than the hind, the animal being often bipedal. Hand usually pentadactyl, foot often tridactyl.

Rhaetic to Upper Cretaceous.

Super-family Ornithopodidae. Families: *Hypsilophodontidae, Camptosauridae, Ignanodontidae, Trachodontidae. Super-family Stegosauridae.* Families: *Scelidosauridae, Stegosauridae, Acanthopholidae, Polocanthidae. Super-family Ceratopsidae,* with one family.

Order 5, Pterosauria. Archosauria fully adapted for flight. The vertebrae and many long bones are hollow and, where occupied by air sacs, arising no doubt, like those of birds, by extension of the bronchi. Skull elongated, triangular in plan, and peculiar in that the quadrato-jugal excludes the jugal from the border of the infra temporal fossa. Teeth may extend throughout the jaws, be restricted to their anterior ends, or be absent altogether.

Cervical vertebrae large, procoelous, and very freely movable, head carried nearly at right angles to the neck. Dorsal vertebrae small, sometimes largely fused, sacrum of four to 10 vertebrae, tail either very short or greatly elongated and quite stiff.

Scapula and coracoids elongated slender rods, the latter articulating with a large shield-shaped sternum. Clavicular arch absent. Ilium long, pubis and ischium fused with it and with each other, not meeting in a median symphysis. Prepubic bones present. Fore limb supporting a wing, which is formed by a fold of skin arising from the side of the body and stretched between the upper arm, fore arm and greatly extended fourth finger, and the hind leg. Fingers one to three, present and clawed.

Sub-order Rhamphorhynchoidae. Pterosaurs, with a long tail, wing metacarpal short, fifth toe well developed.

Upper Trias? Lower Lias to Upper Jurassic.

Sub-order Pterodactyloidae. Pterosaurs, with a short tail, wing metacarpal long, and fifth toe reduced or absent.

Upper Jurassic to Upper Cretaceous. Families: *Pterodactylidae, Ornithocheiridae.*

The birds, class Aves, are certainly descendants of Archosaurian reptiles; had the group become extinct in Cretaceous time it would be regarded as an order equivalent to those listed above.

The remaining reptilian orders cannot usefully be grouped into super-orders.

Order Rhynchocephalia. Reptiles in which the temporal region is perforated by two fossae; the supratemporal fossa seems to differ from that of Archosauria in that the post frontal enters into its margin, whilst the infratemporal fossa differs by the exclusion of the quadratojugal.

The preorbital part of the skull is short, and there is no preorbital opening. The fenestra ovalis is placed high in the skull. The dentary bears a single series of acrodont teeth which bite into a groove between the similar teeth on the maxilla and palatine, so that with use they acquire a wedge-shaped section. The vertebrae have amphicoelous centra, and all the ribs are single-headed An unossified sternum is present. The shoulder girdle includes scapulae, precoracoids, clavicles and an interclavicle.

The pelvis has an ilium attached to two sacral vertebrae and directed downward in front. The pubis and ischia are plate-like in primitive forms, but diverge widely in later times. The limbs are pentadactyl, and the fifth metatarsal has a hook-shaped upper extremity.

One group of Rhynchocephalia, the *Champsosauridae,* became highly adapted to an aquatic life in estuaries.

Middle Trias to Recent. Families: *Rhynchosauridae, Sauranodontidae, Sphenodontidae, Champsosauridae.*

Order Squamata. (The following account does not include the characters of the reptile Pleurosaurus, which is, perhaps, a member of the order.)

Reptiles in which the dermal roof of the temporal region is so far reduced that only a single temporal arcade, or none at all, remains. The quadrate is thereby freed so that it can move, its rounded head articulating with one or two bones which are connected with the parietal. If two bones be present the inner is firmly applied to the front face of the posterior wing of the parietal, and rests against and may even be firmly fixed by suture to the front face of the end of the paroccipital process. This bone is either the supratemporal or squamosal, or, very improbably, tabular. The outer bone is fixed to the lateral surface of the inner, often overlapping it on to the parietal; it stretches forward as the hinder part of the temporal arcade, and meets the postorbital and sometimes the jugal. This bone is either the squamosal or quadrato-jugal. In the palate the pterygoid no longer reaches the prevomers, and the whole is often very lightly constructed.

The vertebrae are usually procoelous, but may be amphicoelous; there are two sacrals or none. Ribs are single-headed throughout. The shoulder girdle, if present and fully developed, consists of scapulae and precoracoids, often enlarged and notched or fenestrated, clavicles, an interclavicle and a sternum. The pelvis has a forwardly and downwardly directed ilium, the pubes and ischia are divergent rods. The limbs are pentadactyl primitively, but may be reduced or absent.

Sub-order Lacertilia (Lizards). Squamata in which a temporal arcade is usually present, and in which the two rami of the lower

jaw are connected suturally at the symphysis. An epipterygoid is present in the normal position and the anterior part of the brain case is very little ossified. The pterygoid articulates with the basipterygoid process of the basisphenoid.

Upper Jurassic to Recent.

Division Ascalabota.

Section Gekkota.

Families: *Ardeosauridae, Gekkonidae, Uropiatidae.*

Section Iguania. Families: *Iguanidae,* and *Agamidae.*

Section Rhiptoglossa. Family *Chamaeleonidae.*

Division Antarchoglossa. Section Scincomorpha. Families: *Xantusiidae, Scincidae, Anclytropiidae, Flyliniidae, Dibamidae, Gerrhosauridae, Lacertidae, Tejidae, Amphisbaenidae.* Section Anguimorpha. Families: *Euposauridae, Varaniidae, Dolichosauridae, Aigialosauridae, Mosasauridae, Pygopodidae, Glyptosauridae, Helodermatidae Anguidae, Xenosauridae, Anniellidae, Zonuridae.*

Sub-order Ophidia (Snakes). Squamata in which the temporal arcade has completely vanished, and the quadrate is very freely movable. The pterygoids have lost all connection with the basisphenoid, and the palate has become mobile, connected to the cranium only by ligaments and by its connection with the maxillae and quadrate. Much of the palate and the maxillae may vanish in burrowing forms. The brain case is completely ossified, the epipterygoid being absorbed into it. The two halves of the lower jaw are loosely connected by all extensible ligament.

The vertebral column is extraordinarily long, in one case containing 565 vertebrae. Each vertebra has a procoelous centrum and a heavy neural arch, on which additional articulating faces, the zygosphenes, and zygantra, are developed. The single-headed ribs are long and are very freely movable antero-posteriorly; by such movements they cause the transversely widened ventral scales to catch the ground, and force the animal along. There is never any trace of a fore limb or its girdle. All three elements of the pelvic girdle may be present in one family, the Glauconidae, but in most this limb is entirely absent. Upper Cretaceous to Recent.

Families: *Typhlopidae, Glauconiidae, Ilysiidae, Uropeltidae, Boidae* (boa constrictors), *Xenopeltidae, Colubridae.* As the last family contains nine-tenths of all known snakes it is subdivided into the series Aglypha (harmless snakes), Opisthoglypha (poisonous but little dangerous to man) and Proteroglypha (typical poisonous snakes).

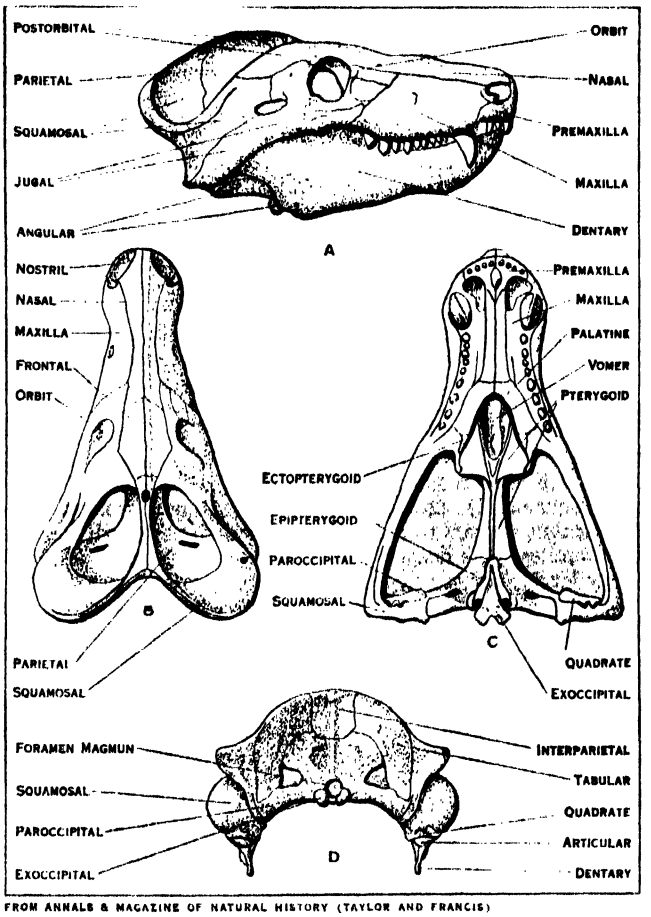
Sub-order Pleurosauria. A small group of extinct reptiles including only one or two genera, which may be related to the Squamata; if so, these are not, as usually held, derived from the Archosauria. Aquatic reptiles with a very long body and lizard-like limbs partially adapted for swimming. Limb girdles of Lacertilian type. Skull elongated and depressed, quadrate short and immovable. There is a single temporal fossa, bounded below by a broad arcade composed of the squamosal, postorbital and jugal. There is no supratemporal, and the outer surface of the quadrate is caused by a quadrato-jugal. Upper Jurassic. One family.

Order Sauropterygia (*Plesiosauria*). Reptiles which show a progressive adaptation to a marine life.

Skull with a single temporal vacuity surrounded by the parietal, squamosal, postorbital and post-frontal, and therefore apparently homologous with the upper temporal vacuity of Rhynchocephalia, and not with the single fossa of Theromorpha and Squamata. The single temporal arcade is formed almost entirely by the squamosal and postorbital, the jugal being a small bone wedged in between the postorbital and the hinder end of the maxilla. A quadrato-jugal is absent. The fenestra ovalis lies high in the side wall of the brain case. The palate is primitive, the posterior nares being anterior, and the pterygoids reaching the prevomers.

Except in Placodonts, the neck is long, often exceedingly so (76 vertebrae in Elasmosaurus), the back is long and the tail short; there are usually three sacral vertebrae, but may be more. The cervical ribs, though double-headed in early forms, articulate only with the centra, the single-headed dorsal ribs being supported entirely by the long transverse process of the neural arch.

The pentadactyl limbs are large, and are more or less completely converted into paddles by a flattening and shortening of the radius and ulna and tibia and fibula, and an increase in the number of phalanges. The shoulder girdle consists of scapulae and coracoids, which meet one another in median suture. Clavicles are probably always present, an interclavicle usually so. The ilium is small, the pubis and ischium, though separated by an obturator foramen, are expanded into flat sheets of bone. A strong plastron of abdominal ribs is always present.



Sub-order 1. Trachelosauria. A single, small reptile, with a long neck consisting of 20 vertebrae whose centra support two-headed ribs. Dorsal ribs single-headed and articulating with the long transverse processes of the dorsal neural arches.

Ilium and femur like those of a land reptile.

Lower Trias.

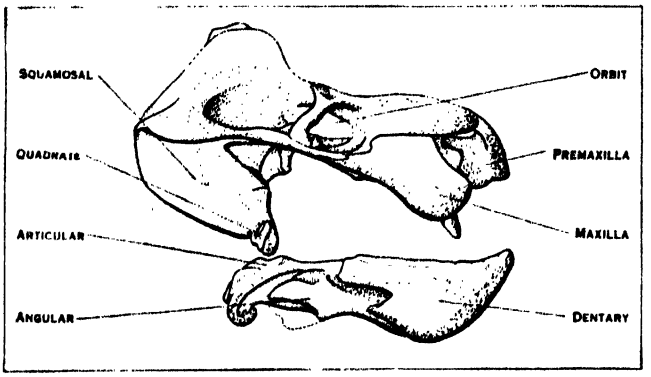
Sub-Order 2. Nothosauria. Sauropterygia in which the limbs are still incompletely converted into paddles, the elbow and knee joints still being flexible. Phalangean formula 2, 3, 4, 5, 3 or 4.

In the skull the opisthotic is enlarged distally, and articulates with the squamosal quadrate and pterygoid, so as to close the middle ear cavity behind. Clavicular arch powerful; coracoids

FROM ANNALS & MAGAZINE OF NATURAL HISTORY (TAYLOR AND FRANCIS)

FIG. 9.—SKULL OF THE CYNODONT, CYNOGNATHUS

A. From the right side, with lower jaw, B. from above, C. from below, D. occiput



meeting in a short symphysis, which lies behind a line joining the glenoid cavities. Ilium articulating with both pubis and ischium.

Middle Trias, perhaps just appearing in the Lower Trias. Families not discriminated.

Sub-Order 3. Pleriosauria. Sauropterygia in which the limbs are completely converted into paddles, with no freedom of movement at any joint; the number of phalanges in the five fingers and toes is increased, reaching 6, 13, 15, 13, 9 or more. The distal end of the opisthotic is slender, resting on the hinder surface of

the squamosal. Clavicular arch, when present, reduced to flat sheets of bone, supported by the greatly enlarged acromia of the scapulae. Coracoids with a symphysis which extends forward between the glenoid cavities. Ilium articulating only with the ischium. Rhaetic to Upper Cretaceous. Families not yet discriminated.

Sub-order 4. Placodontia. Sauropterygia in which the skull has become modified to support great crushing teeth in the maxillae and palatines. Neck with eight vertebrae, the cervical ribs articulating with both centrum and neural arch; dorsal vertebrae with concave articulations, ribs attached solely to the neural arch. Limb girdles essentially like those of Nothosauria, fore limb somewhat paddle-like, but with the primitive number of phalanges, Femur like that of a land animal. A well-developed armour of dermal ossifications both dorsally and ventrally. Middle Trias to Rhaetic.

FROM "PROCEEDINGS" BY COURTESY OF THE ZOOLOGICAL SOCIETY OF LONDON AND DR. PEARSON

FIG. 10.—SKULL AND LOWER JAW OF THE DICYNODONT REPTILE KANNEMEYERIS, RIGHT SIDE

Order Ichthyosauria. Reptiles which are fully adapted for a marine life. The head is elongated, the neck short and the tail very long and powerful, provided with a terminal fin, which is the most important swimming organ.

The limbs are paddles, they are never large, and the hind limbs may become very small. The skull has a single temporal fossa which is surrounded by the parietal, supratemporal (often called squamosal) postfrontal, and sometimes frontal. This opening thus appears to differ in its boundaries from all found in other reptiles. The deep, but usually very short temporal arcade is very largely formed by a bone, often called the supratemporal, which is, perhaps, the true squamosal; it contains also processes of the postfrontal and supratemporal, and a quadrato-jugal. The postorbital and jugal are narrow bones round the enormous orbit.

The nostril lies immediately in front of the orbit, and the long rostrum is built up from the premaxillae and nasals. The biconcave vertebral centra are extremely short, and the neural arches feeble. The ribs are two-headed at least anteriorly, and articulate solely with the centra. There is no sacrum. The hinder part of the tail is downturned very slightly in Triassic forms, nearly at right angles in those from the Upper Jurassic, in order that it may support the lower lobe of a vertical caudal fin whose upper lobe has an unossified skeleton.

The shoulder girdle consists of scapulae and coracoids which meet in a powerful median symphysis between the glenoid cavities, and a rigid clavicular arch. The pelvis has a narrow ilium and pubis and ischia, separated by an obturator foramen, but expanded into great sheets in Triassic forms. In both fore and hind limbs the proximal bone is very short and widened distally, the remainder of the limb, in the later forms, being reduced to an interlocking mass of polygonal bones. The number of fingers is often increased to seven or more, and the phalanges increase to a very great number.

Middle Trias to Upper Cretaceous. Families: *Mixosauridae, Ichthyosauridae.*

Order Chelonia. Reptiles in which the trunk is enclosed in a shell built up from a series of dermal bones, with which the neural arches and ribs become continuous. The limb girdles are unique, in that they lie entirely within the ribs. Skull without any temporal vacuity, but the continuous sheet of bone which, in the primitive forms, overlies the temporal muscles may be emarginated either from the back or from below, or from both, so that in extreme cases the squamosal may be left without connection with any other bones of the skull roof. The powerful vertically-placed quadrate is then only supported by its abutment in the pro-otic opisthotic and pterygoid.

Postfrontals and lachrimals are always, nasals usually absent, and the external nares are confluent. Except in Triassochelys, the jaws are toothless, and they always support a horny beak. There is often a small secondary palate, not homologous with that of mammals or crocodiles, formed by extensions of the palatines and prevomers. The eight cervical vertebrae are so formed that the neck is flexible, bending into a vertical loop in Cryptodeira, and into a horizontal S in Pleurodeira.

The dorsal vertebrae are ten in number, the first being free, or nearly so, from the shell, whilst the rest are fixed immovably by their attachment to the neural plates of the carapace; the two sacral vertebrae are similarly attached. The posterior dorsal vertebrae are peculiar, in that each of their neural arches rests on two centra.

The shoulder girdle consists of a scapula, whose acromian process is produced into a long rod lying horizontally, and approaching its fellow in all forms except Triassochelys, and a coracoid which form a curious pedunculate glenoid cavity. Cleithra are present only in Triassochelys. Clavicles and an interclavicle are entirely detached from the shoulder girdle and form part of the plastron.

The ilium usually articulates, not with the sacral ribs, but with the carapace; the pubis and ischium are lacertilian-like. The limbs are much modified, in order to reach the girdles which lie within the shell, and to allow of their withdrawal in the more primitive forms. The fifth metatarsal is hook shaped. Both feet are pentadactyl, the phalangeal formula never exceeding 2, 3, 3, 3, 3, and being sometimes reduced to 2, 2, 2, 2, 0.

The shell, in its fullest development, consists of a dorsal carapace, built up from a median row of nuchal, preneural, eight neural and two suprapygal bones, and lateral rows, each of eight costals, articulating with the neurals, a variable development of supra marginals may occur secondarily; in their absence the costals articulate with a continuous chain of marginals which connect carapace and plastron.

The plastron consists of three plates anteriorly, the epiplastra which are clavicles, and an entoplastron, the interclavicle; a pair of hyoplastra, two pairs of mesoplastra, one pair of hypoplastra and one of xiphiplastra. The neural bones are co-ossified with the neural spines of the dorsal vertebrae, the costals with the ribs of the second to ninth dorsals.

Sub-order Amphichelydia. Chelonia with no power of completely withdrawing the head within the shell, mesoplastra present, pelvic girdle not fused with the plastron. Families not yet discriminated. Middle Trias to Eocene.

Sub-order Pleurodeira. Chelonia which withdraw the head sideways. Mesoplastra usually present, pelvic girdle fused with the carapace, and usually with the plastron. Families: *Pelomedusidae, Chelyidae, Miolanidae, Plesiochelyidae.* Jurassic to Recent.

Sub-order Cryptodeira. Chelonia which withdraw the head vertically. Mesoplastra absent, pelvic girdle never fused with the plastron. Families: *Thalassemydidae, Chelydridae, Testudinidae, Cinosteriidae, Platysternidae, Chelonidae, Protostegidae, Dermochelyidae, Dermatemydidae, Trionychiidae.* Jurassic to Recent.

There is a considerable number of small Palaeozoic reptiles which do not fall into any of the 19 orders defined above. Of these the more important are: Eosaurus from the Coal Measures of the United States, which may be Cotylosaurian; Eunotosaurus from the Upper Permian of South Africa, which may be an ancestor of the Chelonia; Broomia from the Upper Permian of South Africa, which may be an ancestral lizard; and Araeos-

celis, from the Lower Permian of Texas, which has also been regarded as a lizard ancestor.

The mutual relations of the reptilian orders are illustrated in the phylogenetic tree.

Limbs and Locomotion.—The Lower Permian reptiles of all groups possess limbs which either belong to a definite characteristic type or are clearly simple derivatives of it. In all of them a distinct neck is absent, the body is of circular section, although variable in length, and the tail is usually of considerable size.

The fore limbs were attached to the body immediately behind the head, the upper arm lies parallel to the ground, and was capable of being moved backward and forward only. The elbows were thus pointed directly outward. The forearm lay nearly parallel to the principal plane of the animal, and made a very small angle with the ground. The wrist was large in comparison with the forearm, and the hand possessed five somewhat spreading digits. The hind leg was attached to the body at a considerably higher level than the fore leg. The thigh projected freely from the body, almost at right angles, and the lower leg made a wide angle with it, indeed the stiff knee could not, in many cases, be bent to a right angle. The ankle joint was flexible, and the five toes greatly resemble the fingers of the same animal. As the large head makes the load carried by the fore legs rather larger than that on the hind, the hand is generally larger than the foot.

These animals, like the lizards and salamanders of to-day, threw their backbones into lateral waves as they walked. Their procedure was as follows:—When the animal is standing with its right fore leg advanced to the greatest possible extent, and the right hand on the ground, the head is turned to the left, and the left hand lies near to it but is ready to be lifted. The trunk is thrown over to the right side and the base of the tail to the left. This body flexure implies that the right hind leg is turned somewhat backward and the left hind leg is directed forward. The left hand is then lifted from the ground by movement at the elbow, and carried forward not only by a movement of the upper arm on the shoulder girdle and a straightening of the elbow, but also by a bending of the backbone so that the head becomes directed to the right. This movement of the back involves a corresponding twist of the pelvis, which brings the left hind leg to its backward position, and makes it necessary to lift the right foot from the ground. The right hind leg is then swung forward by motion, mainly at the hip joint, and the foot placed down as far ahead as possible. During these movements the animal, as a whole, has travelled forward and the right hand is ready to be raised. Its movements agree exactly with those of the left, and it is followed in turn by the left hind foot.

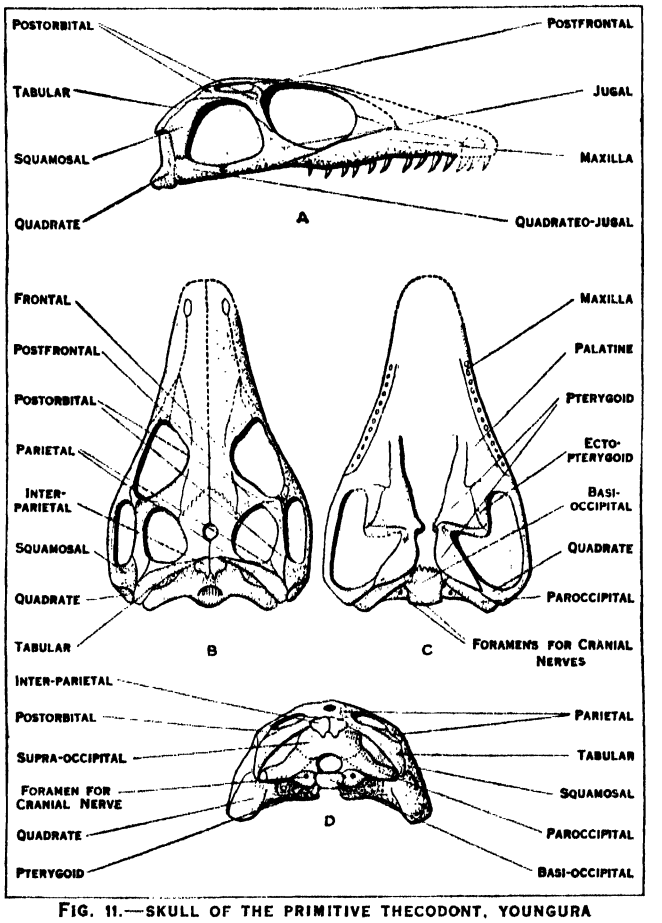
Thus the animal progresses with a waddling gait, the head and body being constantly thrown from side to side of the line along which the animal is moving. The feet are moved one at a time, so that the animal is never standing on less than three of them, and are placed wide apart. This mode of walking must have been extremely slow and clumsy; measurements suggest that a reptile about a yard in length, without the tail, must have made a track 15 in. in width, with a stride of some 6 or 8 inches.

Fossil materials enable us to trace the steps whereby the later reptiles gradually improved their modes of walking, until on one line, they became like the more primitive mammals, walking with their bodies raised high above the ground, the feet brought in towards the middle line and the stride long, whilst along a second course they became bipedal, striding along on their hind legs, with their heads raised high in the air.

The nature of the skeleton and musculature which is associated with the primitive type of locomotion is as follows:—The shoulder girdle consists of the pair of primary elements, each of which is in the most primitive forms, Seymouria and Varanoops, ossified as two bones, the dorsal scapula and ventral precoracoid. The glenoid cavity has a characteristic shape in that its articular surface is a rather narrow screw-shaped strip of a cylinder whose axis is nearly vertical. The glenoid cavity is shared nearly equally by the two bones. The two halves of the primary shoulder girdle do not touch one another in the mid line ventrally; but are held in position with respect to one another by the powerful clavicular arch. This consists of pairs of cleithras and clavicles and an interclavicle. Each cleithrum is firmly attached to the front edge, and sometimes to the upper end of the scapula. The clavicle is firmly attached to the front face of the lower end of the cleithrum and has no contact with the scapula; its lower end is turned inward so as to underlie the thorax, and is usually widened, its lower end underlying the lateral margin of the interclavicle. The interclavicle is usually a thin flat bone, with a widely expanded anterior end, and a narrower shaft projecting posteriorly under the sternum, which is unossified.

The whole girdle was held in position by muscles, the serrati passing from the ribs to the inner surface of the scapula and by others, sternomastoids and cleidomastoids passing from the head to the clavicular arch. Posteriorly, the coracoid is attached to the ventral surface of the abdomen.

The humerus of these reptiles has its extremities very much widened and placed nearly at right angles to one another. The articular surface of the head is screw-shaped, and fits the glenoid cavity so accurately that the bone cannot be rotated, and is restricted to a to-and-fro motion along a definite track. The widened proximal end allows the muscles which pass from the humerus to the ventral part of the animal, the pectoral and coraco-brachials, to have a mechanically favourable insertion. The widened lower end of the humerus similarly secures a



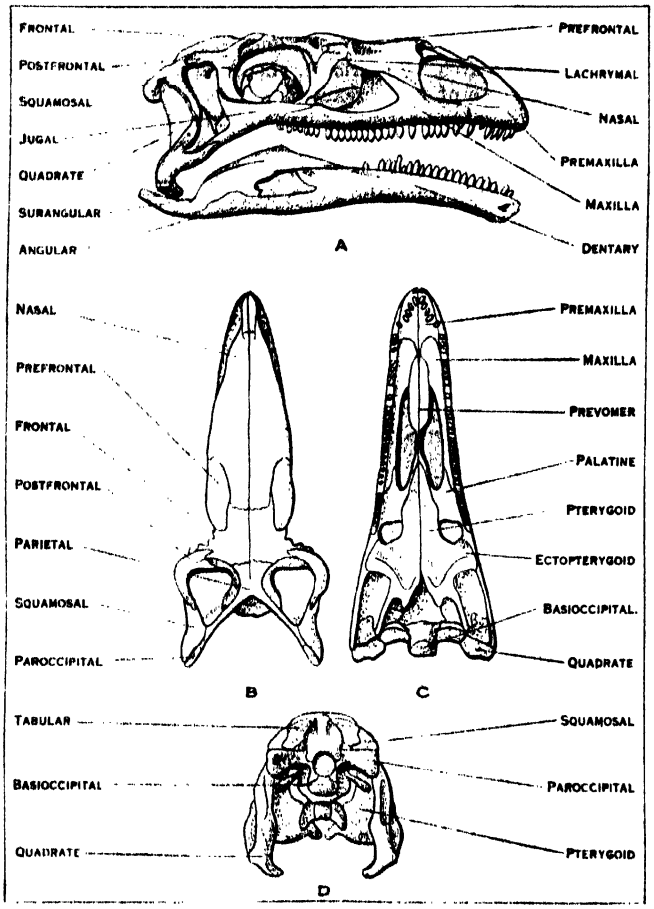


FIG. 11.—SKULL OF THE PRIMITIVE THECODONT, YOUNGURA
A. Right side, B. from above, C. from below, D. occiput

favourable insertion for the flexor muscles which pass from it to the palmar surface of the hand and forearm, and take the whole weight of the anterior part of the body.

The lower end of the humerus bears a hemispherical boss on its front face, with which the head of the radius articulates, and a cylindroid articulation on its end which fits into the sigmoid notch of the ulna. The distal ends of the radius and ulna are widely separated; they articulate with the four bones: radiale, intermedium, ulnare and pisiform, of the proximal row of the carpus. The middle row of the wrist usually consists of only two

bones, the centralia, one of which forms part of the inner border, whilst the other separates the intermedium from the distal row. This consists of five bones, of which the fourth, which articulates with the ulnare, is the largest. The metacarpals articulate directly with the corresponding carpals and the number of phalanges is 2, 3, 4, 5, 3 respectively. This ensures that the ends of the fingers lie in a straight line at right angles to the animal, when the hand is placed on the ground.

The pelvis is attached to the vertebral column by the sacral ribs, which vary in number in Lower Permian reptiles from one

to four. It consists of three pairs of bones, the ilia, pubes and ischia. These meet in a triradiate suture, so that each supports about one-third of the acetabulum, with which the head of the femur articulates. The pubis and ischium of the same side are firmly united by a continuous suture and the two halves of the pelvis articulate continuously, so that the whole structure is usually described as plate-like. The femur is a straight bone, with the articular face of its head placed on the end of the shaft. The condyles at the distal end are only slightly curved, well separated and placed at such an angle as to suggest that the knee could neither be extended into a straight line nor flexed beyond a right angle.

The tibia is a bone with an expanded upper end, and is always shorter than the fibula, which is unusually massed. At their lower ends the two bones are widely separated. The tarsus, in one case (Seymouria) has a proximal row of three bones, the tibiale intermedium and fibulae, corresponding with those of the carpus, but in nearly all other reptiles and their descendants, the mammals and birds, the intermedium is no longer found as an independent bone, even during development, and has fused with the tibiale to form an astragalus. As a result of this fusion the tibia articulates only with the astragalus, whilst the fibula impinges on both astragalus and fibulare or calcaneum. The calcaneum is always in direct contact with the fourth and fifth (if present) distal tarsal, whilst the astragalus is separated from the first three distal tarsals by a row of two or more, usually one, centrale, the mammalian navicular. There are primitively five digits, the fourth being the longest. The phalangeal formula is 2, 3, 4, 5, 4.

The great majority of the changes which take place in the structures of these limbs during the evolution of the reptiles can be explained by a consideration of the mechanics of the structures under modified conditions of locomotion.

In the line of the mammal-like reptiles, and also in some of the other forms, the first change which takes place in the shoulder girdle is the addition of a bone, the coracoid, to the two existing in the primary shoulder girdle. These animals then acquire a pectoral girdle which resembles the pelvis in that the facet for articulating the proximal bone of the limb is carried almost equally on three bones. The glenoid cavity at first retains its screw shape, the humerus being restricted in its motion to an excursion along an arc lying nearly parallel to the ground. Gradually, as an integral part of the whole process whereby these animals acquired a more rapid and less clumsy gait, the plane of this glenoid cavity becomes twisted round, so that the humerus moves freely in a dorso-ventral direction and the elbow is no longer directed outward, but is drawn in toward the side of the body, nearly to the stage in which it exists in the more primitive mammals. This change results in the restriction of the glenoid cavity to the scapula and coracoid alone, the precoracoid no longer contributing to it.

Concurrently with this change, the humerus took up a more vertical position, so that the muscles connecting it with the coracoid could become smaller, in part because the forces they had to exert were actually reduced and, in part, because their insertion became more favourable. Thus the coracoid and precoracoid suffer steady reduction compared with the scapula. Finally, in order to secure a larger surface for its attachment, one muscle, which serves to support the animal's weight and to drive the humerus downwards, migrates on to the inner surface of the scapula, the tendon by which it is attached to the humerus passing over a notch in the front border of the scapula below the point at which the clavicle is attached to that bone. In this way a definite acromium becomes established, and the upper part of the anterior border of the scapula becomes recognizable as the homologue of the spine of a mammalian scapula.

The most important change in the clavicular arch is the gradual reduction and final complete disappearance of the cleithrum. The other bones sink in from their original position in the skin, so that they become surrounded by muscles on all sides, but otherwise they suffer comparatively little change during the evolution of the mammals.

The great changes in the position of the fore limb during the development of the mammal-like reptiles necessitate corresponding modifications of the structure of the humerus and other limb bones. Of these, the most striking is the gradual narrowing of the two ends of the humerus and their rotation until they become nearly parallel.

In the hand, the number of phalanges in the third and fourth fingers is reduced to three, so that the formula becomes that characteristic of mammals, 2, 3, 3, 3, 3. It is evident that this change is associated with a new pose in which the third finger, which becomes the longest, lies parallel to the mid line of the animal and the others are symmetrically placed on each side of it.

In the pelvis, the most important changes are a widening of the upper part of the ilium associated with an increase in the number of vertebrae in the sacrum, and the development of an obturator foramen, a gap lying in the suture between the pubis and ischium.

The femur so changes its shape that it can lie with the knee directed as much forward as outward, and the lower leg become capable of much freer movement. At the same time the astragalus and calcaneum shorten so that the tibia and fibula rest partly on their upper surface, thus forming an ankle joint which is on

the way to a mammalian structure and the phalangeal formula of the foot becomes reduced to 2, 3, 3, 3, 3.

The non-mammal-like reptiles exhibit so many different types of adaptation that a full analysis of the structures of their limbs is impossible; indeed, it has not yet been systematically attempted. Some of the main types of life are here discussed with reference to a particular case.

Nondescript.—The majority of lizards and Rhynchocephalia exhibit a simple modification of the mode of locomotion found in the most primitive reptiles. In them the body and tail are thrown into lateral waves, which pass steadily backward so that each point along the back swings from side to side across the animal's track as the creature moves forward. The hands and feet are widely separated, the body only just raised off the ground, and only one foot is moved at a time. In detail there is much variety; both fore and hind feet may be much everted, so that the first digits point forward and the toes increase in length from one to four, so that when in the natural position their claws end on a straight line at right angles to the body. In some cases, however, the fingers are directed forward and the hand is nearly symmetrical about the third finger, and even the foot is less asymmetrical than in the more primitive forms. Nevertheless, these animals always retain the original phalangeal formula.

These animals have a primary shoulder girdle consisting of a scapula and precoracoid, the glenoid cavity has lost all trace of the screw shape of primitive reptiles and permits considerable freedom of motion. In the larger and more advanced lizards the anterior part of the scapula and coracoid is much enlarged, and these bones are perforated by fenestrae.

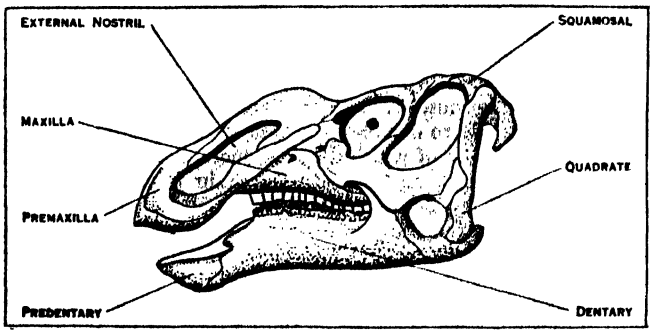
The clavicles have an expanded, and sometimes fenestrated, lower end, and the interclavicle is usually cross-shaped. There is a large sternum, which is usually calcified although not ossified, with whose antero-lateral borders the precoracoids articulate.

The pelvis of these reptiles is of very characteristic pattern, the ilia are narrow rods with an expanded lower end which contributes to the acetabulum. It slopes downward and forward and is firmly held by its articulation with the two sacral ribs. The pubis and ischium are separated by a large obturator foramen which, in many cases in the bony skeleton, is confluent with that of the opposite side. The hind limb presents few features of interest, but it may be noted that a patella is sometimes present, and that most of the motion at the ankle-joint takes place between the two rows of tarsals and not, as in mammal-like reptiles, between the tarsus and lower leg.

One universal and unexplained feature of the hind foot of these reptiles is that the fifth distal tarsal is absent, and that the upper end of the fifth metatarsal has moved up into contact with the calcaneum, and has become much widened so that the whole bone is hook-shaped. As a result, the fifth toe tends to be widely separated from the other four.

This feature occurs in Rhynchocephalia, Thecodontia, Crocodilia, Dinosauria, Squamata, and Chelonia, and has been held to imply a close relationship between these orders.

Cursorial Progression.—The only group of non-mammal-like reptiles which became highly adapted for rapid progress on hard land was the Dinosauria. They arose from Thecodonts whose general body proportions and gait generally resembled those of certain lizards. These animals possessed slender scapulae and small precoracoids, clavicles and interclavicle were present, and there was, in some cases, a sternum with a single pair of ossifications. The fore limb was slender, the hand small and with five fingers. The pelvis had an ilium which was antero-posteriorly extended, but so low that the acetabulum lay on the level of the vertebrae. The pubis and ischium were plate-like, but much elongated and directed largely downward. The hind legs were much longer and more massive than the fore, a condition made possible to a quadripedal animal by the presence of a long tail, which acted as a counterpoise to the body. Although it is certain that these animals had a straddling gait, it is probable that the feet were placed unusually near to the middle line and the feet were not so asymmetrical as those of most lizards.



From such reptiles the Saurischia, the carnivorous dinosaurs arose by an increase in the length of the hind legs, and concurrent reduction of the arms. They became predominantly bipedal, a habit which necessitates the raising of the body so far above the ground that the whole animal balances about the pelvis. This pose can only be attained if the thighs are turned in until they lie parallel to the body of the animal, and the feet are placed on the line which marks the middle of the track. Such an arrangement ensures that the body need no longer be thrown from side to side, as it is in all more primitive reptiles.

A further result is that, as the powerful muscles which are used for propelling the animal forward no longer press the heads of the femora into the acetabula, this depression no longer needs a floor and becomes perforated. At the same time, in order to lengthen the muscles attached to them and thus enable the leg to swing through a larger area, the pubis and ischium, both elongated, stretch downwards and away from one another, meeting only at the acetabulum. The reduction in size of the forelimb, which occurs because it is no longer required to carry the weight of the body, results in a reduction and final loss of the clavicular arch, and in a reduction in size of the precoracoid. Subsequently, certain carnivorous dinosaurs increased greatly in size and became quadripedal again, retaining in many parts of their skeleton features which arose during the bipedal stage in their ancestry.

The long limbs which are necessary for a bipedal cursorial life, involve elongated feet. These are secured by lifting the heel entirely off the ground, so that the animal walks on the ends of the metatarsals, the toes stretching out along the ground as they do in birds. As the foot is placed directly under the body it tends to become symmetrical about the middle third toe, and rapidly becomes either functionally or actually tridactyl. The hand, which serves as a grappling hook for catching the prey, is reduced to three fingers, all provided with claws, that on the thumb becoming very large indeed in the latest forms.

The other group of dinosaurs, the Ornithischia, pursue a somewhat similar course of modifications; they also become bipedal, some of them secondarily returning to a quadripedal life. But in them the extension of the pubis and ischium into long downwardly directed rods, which is necessary to afford suitable muscle attachments, takes place in such a way that the pubis acquires two branches, one directed downward and forward, the other directed backward so that it lies parallel to the ischium. The early stages of this arrangement are not known, but it persists throughout the whole group.

Flight.—One group of lizards, the genus Draco, has the habit of living in trees and of passing from tree to tree by making great

BY COURTESY OF THE GEOLOGICAL SURVEY, DEPARTMENT OF MINES, CANADA

FIG. 13.—SKULL AND LOWER JAW OF THE ORNITHOPODOUS DINOSAUR KRITOSAURUS

leaps, whose length is extended by the presence of a parachute, made by flaps of skin which project from the sides of the body and are supported by the much elongated ribs. Such gliding is scarcely flight in any true sense, it cannot be maintained by any action of the animal whilst in the air, and its extent is limited by the speed acquired at the original jump and by the height of the point of departure. A similar gliding habit, carried out without any elaborate mechanism by a mere concavity of the ventral surface, is exhibited by certain arboreal snakes from Borneo. The only reptiles which have acquired true flight were

the extinct Pterodactyls.

There are two series of the animals, in one of which the tail is extremely short and probably functionless, whilst in the other the tail is a very long stiff rod bearing a horizontal fin at its hinder end. The presence of this fin renders the maintenance of the body on an even keel much easier than it can have been in the tailless forms. The wing of every pterodactyl consists of a fold

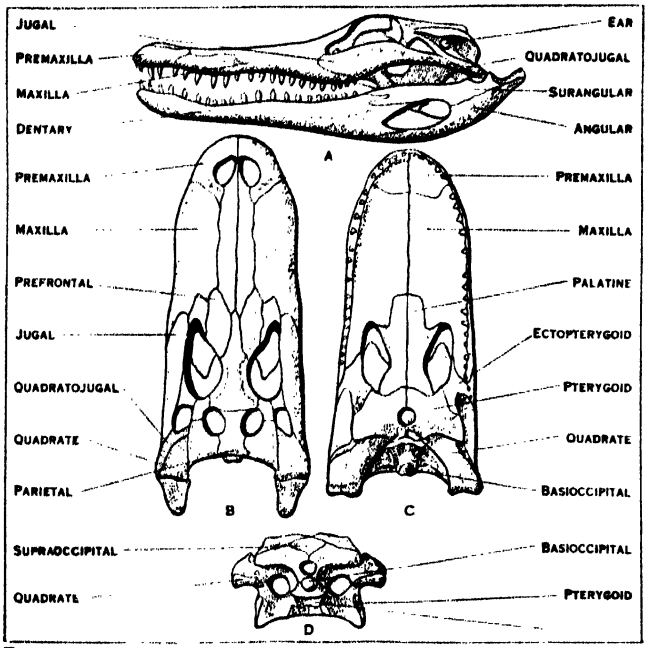


FIG. 14.—SKULL OF A CROCODILIAN, THE ALLIGATOR; (A) LEFT SIDE, WITH LOWER JAW, (B) FROM ABOVE, (C) FROM BELOW, (D) OCCIPUT (AFTER ANDREWS)

of skin which is supported by the greatly extended fourth finger and by the hind leg; it may or may not have connected the hind legs together, either directly or by passing on to the base of the tail. The structure of the fore limbs, which enabled these animals to perform automatically the many carefully-adjusted movements which are necessary for flight, is so strictly determined by mechanical considerations that it is practically uniform in all known species of the group.

In all of them, the scapula is an elongated narrow rod of bone which may articulate with the neural spine of the dorsal vertebrae. Its lower end forms the upper half of the glenoid cavity and is fused with the coracoid. This bone is elongated and straight, its distal end rests in a groove in the front of the large sternum, so that it is enabled to take directly the stresses resulting from the powerful wing muscles. The humerus is short, and the radius and ulna lie parallel to one another. The carpus consists of three bones, with the distal of which the wing metacarpal is articulated, so that it can revolve on its axis. The main joint at which the wing was folded lay between the metacarpal and first phalanx. The movements at the elbow and wrist are inseparably connected, and serve to alter the camber and angle of attack of the wing, thus enabling the animal to fly at varying speeds. It is interesting to note that a successful aeroplane, with an unusual range of flying speed, has been designed on lines suggested by the tailless pterodactyls.

Swimming.—Two extreme modes of swimming are open to a tetrapod. It may convert its limbs into paddles by whose actions it rows itself through the water, or it may use its tail as a propeller, either flattening it and causing waves to pass along its length or producing a fin at the extreme tip, which can be used like a screw propeller. Both types are found in reptiles.

The Chelonia include amongst the fresh water tortoises a number of animals which swim well with limbs which, except for the webbing of the toes, are much like those of a land animal. But in the marine turtles and in the fresh water Carettochelys from New Guinea, the limbs are transformed into paddles, mere bags of skin surrounding the whole of the elongated digits.

The Plesiosaurs carried this principle to its limit; in them each limb is a rigid oar, flattened and widened distally, circular in section where attached to the body. It was feathered when brought forward, then turned so that its broad plane was vertical for the swimming stroke.

The crocodiles, the semi-marine lizard Amblyrhynchus, and the sea snakes are the living exponents of the second mode of swimming. In them the powerful tail is laterally flattened, and is swung from side to side so that a series of waves passes along its length. The limbs are used for steering and for maintaining stability in the water. The only groups of reptiles which have formed a caudal fin are the Ichthyosaurs and the marine crocodiles of the family Metriorhynchidae. In each case the end of the vertebral column is suddenly turned down so that it passes into the lower lobe of a forked fin whose upper lobe is supported only by non-ossified structures. These animals show a reduction of the limbs, the pelvic limb of Ichthyosaurs and the pectoral limb of the crocodiles being reduced to a tiny paddle.

Limblessness.—Many lizards belonging to unrelated families, but chiefly of burrowing or sand living habits, exhibit a reduction of limbs associated with an elongation of the body. The process takes place gradually, all stages being known in one or other form between normally developed limbs and their complete absence. In snakes the reduction is always complete in the case of the fore limbs, whilst the hind limbs may be represented by a claw-like spur on each side of the vent. In some cases all three bones of the pelvis and the femur may be present. Normally, all trace of limbs, except for a rudimentary nerve plexus, is lost.

Skin.—The fact that the reptiles were originally distinguished from the amphibians by their more completely terrestrial habits, implies that in them the skin had become capable of withstanding desiccation, and the serious wear to which it became exposed.

The skin of amphibians is maintained in good condition by a coat of mucus, poured out from glands which lie all over it; that of reptiles is dry and covered by a watertight layer of horn, very well adapted for resisting abrasion. The horny layer, though continuous, is not of the same thickness throughout, but is divided into specially thickened areas, the scales which are connected by flexible regions. The scales may be flat, fitting together like a mosaic or separated widely, or they may be prolonged backwards so that they overlap and are overlapped by others, like slates on a roof. The scales often have a definite arrangement, which is used in the classification of Squamata.

The skin, as in other Amniotes, consists of a compound squamous epithelium which rests on a corium built of connective tissues. The actual scale consists of the keratinized outer layers of the epidermis, its thickness is increased by additions to its inner surface, and it grows in area either all round or at one end. The area of the scale is always raised by a special papilla of the corium, which may project so far that the scale overlaps that behind it. The scale is colourless, its transparency allowing the pigment in the catis to show through.

The outer layer of the keratinized epithelium is worn away in crocodiles and Chelonia, but in the Rhynchocephalia and Squamata it comes away either in flakes or, in some lizards and snakes, in one piece. Such cast skins exhibit perfectly the continuity of the horny skin, which in them even covers the eyes. This process of shedding the skin is facilitated in some or all of these reptiles by a special mechanism which allows the head to be distended with blood. The papilla of the corium which fills the centre of each scale may, in crocodiles, some lizards and many fossil reptiles, be ossified as a bony scute.

The carapace and plastron of the Chelonia consist essentially of such scutes. Each ossifies in the corium, the bone finally occupying nearly the whole thickness of that layer, leaving only a thin sheet of connective tissue to support the peritoneum, and a similar sheet containing pigment cells below the epidermis in which the horny shields are developed. The originally dermal ossifications of the carapace extend so far down into the body of the animal that, in the end, they completely surround the middle parts of the ribs, which first calcify and are then ossified by ex-

tension of membrane bone from the scute.

Most of the glands found in the skin of reptiles are scent glands, which give to these animals their characteristic odour of musk, which has, no doubt, a sexual significance. All these glands are sac-shaped, multicellular structures opening by a pore on the surface, and their secretion is set free by disruption of cells.

The musk glands have the following distribution:—In crocodiles there is a pair which open by longitudinal slits on the inner sides of the lower jaws, and another pair lie within the lips of the cloaca; these are present in both sexes. Crocodiles possess also a row of small sac-like glands without external openings along each side of the back.

In Chelonia there is a pair of inguinal glands opening near the hypoplastra, and sometimes an anterior pair similarly related to the hyoplastra. Sphenodon has a pair of cloacal glands. Lizards have cloacal glands and, in addition, in certain forms there are the so-called femoral pores, which extend along the lower and hinder surface of the thigh to pass on to the belly in front of the cloaca. They are present in both sexes, but best developed in males. Each pore opens in the middle of a scale and leads into a canal which ends in a pocket with many shallow diverticula. The cells of the walls of these become detached, filling up the lumen of the gland and duct, and forming a rod which may project beyond the surface of the skin. It is possible that these structures are of assistance in copulation.

Muscular System.—No useful account of the muscles of reptiles can be given here, the functional effects of those used in locomotion are described in the section *Locomotion*.

Body Cavity.—The body cavity of reptiles is always more or less completely divided into sacs. A completely closed pericardium is always present. In lizards, a post-hepatic septum built up by special folds of the mesentery and suspensory ligament of the liver, may reach the ventral surface and bring about an almost complete division of the peritoneal cavity into two. In snakes, similar folds enclose the two lobes of the liver and the stomach in separate sacs. In Chelonia, the lungs lie above a fold of peritoneum which reaches the liver, excluding them from the general cavity. In crocodiles, there are two pleural cavities and a combination of other folds connected with the liver forms a complete transverse partition separating the pericardium, lungs and liver from the rest of the peritoneal cavity. This sheet is muscular, and probably functions in respiration like the non-homologous mammalian diaphragm.

Digestive System: Teeth.—The teeth of reptiles may be found on the pre-maxillae, maxillae, on all the bones of the palate, and on the dentary and coronoid bones of the lower jaw. Individual teeth are generally simple cones with a conical pulp which produces dentine and an enamel cap. They may be set in sockets (thecodont) or fused to their supporting bone (acrodont or pleurodont). In the majority of reptiles they are shed periodically, and replaced as often as necessary. In reptiles, the marginal teeth of both jaws appear to belong to two series, whose members alternate with one another, and in primitive forms were functional alternately.

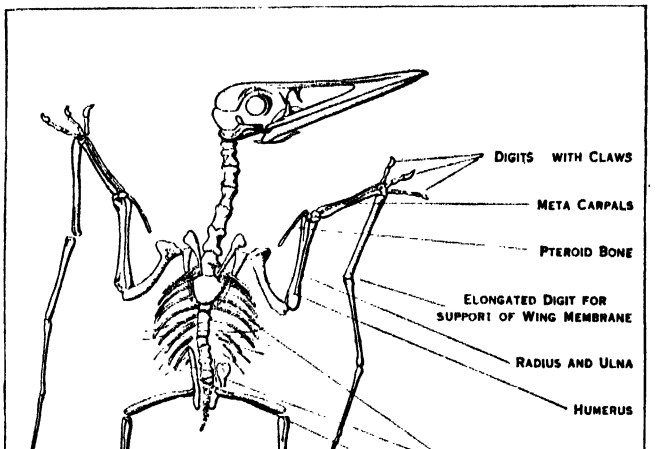
Thus, in these animals two teeth are usually separated by an empty emplacement in which a new tooth will arise, the original pair being shed together when it has grown to its full size. When the original teeth have been shed a new dental papilla passes outward from the lingual side to the empty socket and there produces a new tooth. In crocodiles this process has already happened before the tooth is shed, so that these new tooth crowns may often be found in the pulp cavity of the original tooth. Sphenodon, and some other recent reptiles with acrodont teeth, exhibit no replacement after maturity has been reached. The mammal-like reptiles in their various orders show all stages in the reduction of tooth change from the primitive unlimited replacement of all teeth to a mammalian condition in Cynodonts, where the incisors, canines and pre-molars are replaced once during the animal's life, and the molars, when once formed, are never shed.

The dentition of reptiles is usually homodont, that is, uniform or regularly varying from front to back of the jaw, but the Theriodont dentition is heterodont and mammal-like. The tooth crown may be elaborated into a crushing mechanism, in Placodonts, some Ichthyosaurs, and very effectively in the Trachodont dinosaurs, where several successive series of teeth are in use at one time, forming a splendid triturating surface, in Cotylosaurs, Theromorpha, and even, though imperfectly, in some lizards. The peculiarly specialized fangs of poisonous snakes are described in the article on these animals.

Tongue.—A tongue is present in all reptiles. In crocodiles and Chelonia, it is a short, broad, fleshy structure attached to the floor of the mouth over a large area. In crocodiles, a fold on the hinder margin of the tongue engages with a similar structure of the palate, so as completely to separate the air passage from that for food. In lizards the tongue may be flat, broad and not protrusible; it may be narrow, cylindrical and capable of being extended out of the mouth, or its cylindrical anterior half may telescope into the posterior portion, so that the whole can be projected far in front of the snout. This last type reaches its climax in the chameleon (*q.v.*).

Buccal Glands.—The only salivary gland of universal occurrence in reptiles is a sub-lingual. Upper and lower labial glands occur only in lizards and snakes, where they are arranged in rows between the lips and the teeth. The poison glands of the lizard Heloderma, and of the snakes, are special developments of such upper labial glands. They are described in the article SNAKE.

Gut.—In Chelonia, Sphenodon, lizards and snakes, the oesophagus passes gradually into the stomach, which is, in them, usually spindle-shaped, with its openings widely removed from one another. In crocodiles, the stomach is placed more transversely, the opening of the oesophagus and the pylorus being approximated. This stomach is an oval sac whose proximal portion is very muscular, recalling, in its arrangement, the gizzard of a bird; indeed, it customarily contains pebbles used for triturating food. The pyloric end of the stomach is distinct. The stomach always contains gastric glands.



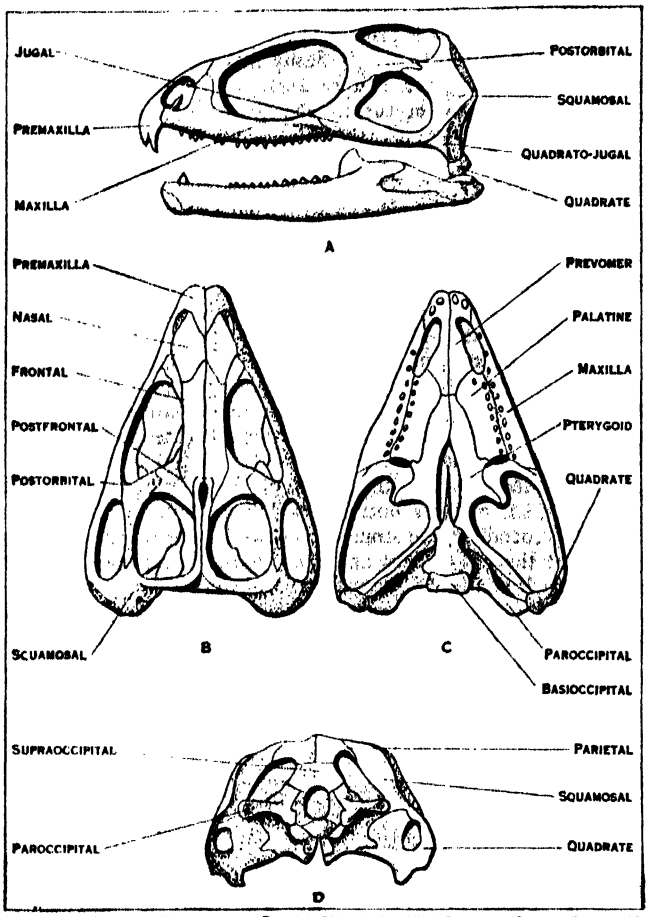


FIG. 15.—PTERODACTYLUS SPECTABILIS FROM THE LITHOGRAPHIC STONE

A pyloric valve usually exists, and the duodenum is not usually sharply marked off from the rest of the small intestine; only in crocodiles does it form a loop round the pancreas as it does in birds and mammals. The walls of the mid gut are usually thrown into folds or ridges, but seem to contain few or no glands. There is usually or always an ilio-colic valve separating the mid from the hind gut; immediately beyond this the latter gives rise to a caecum in some lizards and snakes. The rectum ends in a cloaca which is usually of elaborate structure.

Cloaca.—The cloacal opening leads into a proctodeum, a cham-

ber whose walls give origin to the copulatory organ or organs in the male, and their representative in the female duct to the pair of anal glands; the peritoneal canals when present open into it.

Copulatory organs are absent in Sphenodon, in Squamata they are a pair of papillae capable of being protruded through the lateral ends of the transverse cloacal slit, and of being retracted, being turned inside out by the contraction of special muscles

FROM WILLISTON, "WATER REPTILES OF THE PAST AND PRESENT" (UNIVERSITY OF CHICAGO PRESS)

FIG. 16.—SKULL OF THE RHYNCHOCEPHALIAN, SPHENODON: (A) LEFT SIDE, (B) FROM ABOVE, (C) FROM BELOW, (D) OCCIPUT

derived from the tail musculature. Each has a groove on its lateral surface which extends on the wall of the cloaca nearly to the opening of the vas deferens. In crocodiles and Chelonia, a median unpaired penis arises from the ventral wall of the proctodeum; it can be erected through the activities of corpora cavernosa, and is then extruded through the anterior end of the longitudinal cloacal slit. The dorsal or posterior surface of the penis is furrowed by a deep groove, which is probably converted into a canal during erection. The groove leads backward to the openings of the seminal ducts.

The proctodeum is separated by a ridge which is, in effect, a sphincter, from the urodaeum, into which the ureters, vasa deferentia, oviducts and bladder open. A bladder is found in Sphenodon, Chelonia and most lizards; it is absent in all other reptiles. The urodaeum is partially subdivided in many reptiles; in snakes a dorsal recess receives the ureters and gonoducts; in crocodiles they open into the dorsal side of the urodaeum, whilst in Chelonia they discharge directly into the neck of the bladder. In Sphenodon, lizards and snakes, the oviducts open rather dorsally, in crocodiles and Chelonia ventrally, the vasa deferentia having a similar opening in all forms.

The urodaeum is, in some aquatic Chelonia, produced into a pair of their walled sacs on the dorsal side, which are constantly filled and emptied of water, thus serving as accessory respiratory organs. In all reptiles except crocodiles and Chelonia there is an additional cloacal chamber, the coprodeum, which serves for the storage of faeces.

Urogenital System.—The kidney of an adult reptile is always a metanephros, discharging by a single ureter. The kidney may be elongated and its surface furrowed, or it may be a small compact organ. The urine of Chelonia and Crocodilia is fluid, that which is voided by snakes and lizards contains crystals of insoluble urates, an arrangement which prevents waste of water in these animals, which often live in very arid surroundings.

The ovaries are always paired, and large owing to the size of the yolky eggs. Interstitial tissue is small in amount. The oviducts have independent funnel-shaped ostia, and are usually provided with glandular walls which secrete the albumen and shell. In some viviparous forms they can combine with the faetal membranes to form a placenta. The elongated testes are connected with an epididymis of mesonephric origin.

Respiratory System.—All reptiles breathe by lungs. These are always produced by the elaboration of a median ventral outgrowth of the pharynx. The glottis lies immediately behind the tongue and is sometimes protected by a rudimentary upstanding epiglottis. There is a larynx, supported by arytenoid and cricoid cartilages, there being no thyroid cartilages; muscles passing from the laryngeal cartilages to the "hyoid" enable the glottis to be opened and closed. There are often vocal chords, which give to Sphenodon, crocodiles, some tortoises and lizards a voice, usually a grunt or squeak. The trachea is often long and its cavity is kept open by cartilaginous rings. The bronchi may be very short in Sphenodon or very long in tortoises. The lung is very variable in its structure; it may be almost as primitive as in Amphibia or become comparable to that of a bird.

In Sphenodon and snakes the cavity of the lung is single, but the walls are divided up into a series of cells by upstanding ridges or septa. In some lizards certain of these septa elongate so that the original single sac begins to be cut up into lobes, each with cellular walls. In crocodiles, this process has gone on so far that the lung is definitely divided into a number of chambers each of which receives a number of wide side canals, the parabronchi, in whose walls lie the alveoli. In Chelonia this process has gone so much further that the whole lung is spongy, the alveoli, through whose walls the whole of the respiratory exchange takes place, being connected with an irregularly branched series of bronchial tubes.

Not only is the actual structure of the lung altered in this way, but reptiles show an advance over the Amphibia in an increased size of the lung resulting from the development of a special anterior projection, the prebronchial part, which, very small in Sphenodon, becomes much more extensive in more advanced reptiles. In chameleons, long, hollow non-respiratory process of the lungs pass backward among the viscera; they are important as morphological forerunners of the air sacs of birds and Pterodactyls. In elongated legless reptiles one of the lungs is usually reduced, and may be absent.

The mode of respiration in Reptilia is not well known. In all except the Chelonia, movements of the ribs may be expected to draw air into the lungs, whilst the muscular post-hepatic diaphragm of crocodiles is, no doubt, used as is the comparable structure in mammals. In Chelonia, and probably also in other reptiles, air is actively forced down into the lungs by movements of the floor of the buccal cavity brought about by the hyoid and its musculature. In Chelonia, the protrusion and withdrawal from the shell of the neck and legs gives a pumping action which, by creating a virtual vacuum, draws air into the lungs.

Vascular System.—The heart of reptiles lies in the thoracic region, usually between the lungs. There is a sinus venosus, at least in most, which opens by a valve guarded slit into the right auricle. Right and left auricles are completely separated, and open independently into the ventricle or ventricles. The lower edge of the interauricular septum is expanded laterally into, usually, very large right and left membranous valves, which direct the arterial blood to the left, the venous to the right side of the ventricular cavity. The ventricle is incompletely, or, in Crocodilia, completely divided by an upstanding ridge into right and left

halves. Except for a possible relic in Sphenodon, there is no trace of a conus arteriosus nor of a truncus. Three arteries arise independently from the ventricle, and are then twisted round one another like a rope, so that they cross one another. That vessel whose origin is most to the right is the left systemic arch, the next is the pulmonary arch, and the third is the right systemico-carotid, from which arise both carotids. As a result of this arrangement, in Chelonia the pulmonary arch arises from a partially separated cavum pulmonale, and the two systemics from a cavum venosum, which has to be traversed during systole by the blood from the left auricle, which is originally discharged into the cavum arteriosum on the left side of the ventricle. In crocodiles, the right systemico-carotid alone leaves the left ventricle, whilst both pulmonary arch and left systemic come off from the venous right ventricle: but in them the left and right systemics are connected by a special opening, the foramen of Panizzi at the point where they cross. Although it has been shown by the electrocardiograph that the nature of the contraction of the heart in tortoises is much as in mammals, very little is known of its general physiology.

Arterial System.—The pulmonary arch soon divides into two branches, one to each lung; in Sphenodon and some lizards it gives off a paired laryngotracheal artery which is a relic of a

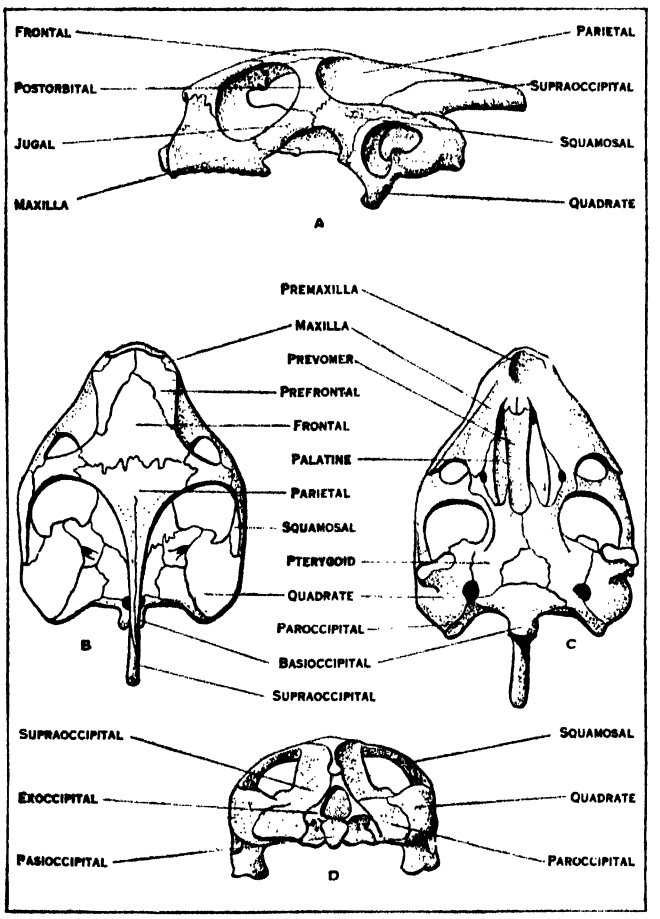

FIG. 17.—SKULL OF A TORTOISE, TESTUDO
A. Left side, B. from above, C. from below, D. occiput

Urodela structure. The systemic arches unite to form the dorsal aorta; from one or both of them arise coronary arteries to the heart. From the right come off both subclavians, and the left usually gives off a coelic branch. The carotids may arise independently from the right systemico-carotid, or may be formed by the branching of a single primary carotid. In snakes the right carotid is usually much reduced or absent.

Venous System.—The venous system is exceedingly complicated, differing in details in the four orders but with a common ground plan. The pulmonary veins pass straight from the lungs into the left auricle.

The venous blood is returned to the heart by the pair of precaval, and single postcaval veins which open into the sinus venosus. The branches of the precavals come from the head and fore limb, the subclavian often receiving an azygous vein from the anterior part of the body wall which represents part of the embryonic posterior cardinal. Nearly the whole of the blood which

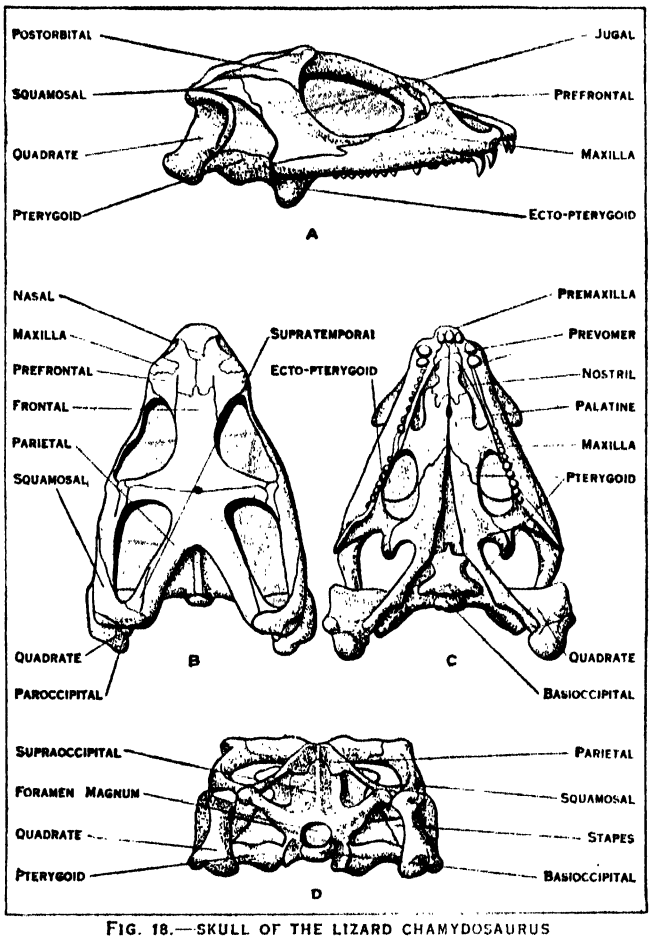

FIG. 18.—SKULL OF THE LIZARD CHAMYDOSAURUS
A. Right side, B. from above, C. from below, D. occiput

enters the heart through the postcaval has previously passed through one of these portal systems.

The renal portal system drains the tail, and part of the hind limbs, the afferent renals arising from the bifurcated anterior end of the caudal vein and the iliacs. The efferent renals open into the postcaval, whose hinder end is formed by them. The supra renal portal system consists of a series of afferent veins which come from the body wall; the efferents discharge with the gonadial veins into the postcaval.

The hepatic portal system includes the series of veins from the gut, which form the true hepatic portal vein and also the median anterior abdominal vein, which is originally formed by a fusion in the middle line of pelvic veins, themselves built up from the iliacs and a series of vessels from the hinder part of the body wall of the abdomen. The anterior abdominal passes along in a mesenteric sheet in the ventral part of the body cavity to enter the liver and there receive the hepatic portal or a branch from it. Finally, the whole of the blood in the liver passes by the hepatic veins into the posterior cardinal.

Lymphatic System.—Definite lymphatic canals are well developed in reptiles; those of the head unite into thoracic ducts which open into the innominate veins. There is a pair of posterior lymph hearts discharging into the iliacs.

Blood.—The red blood corpuscles are oval, biconvex and nucleated; they are larger than those of birds and mammals, smaller than those of Amphibia.

"Ductless Glands."—A spleen is constantly present in reptiles, placed near the stomach or within the loop of the duodenum behind the pancreas. The reptilian thyroid is a median structure placed somewhere on the ventral surface of the trachea.

There are two pairs of thymuses in Sphenodon and lizards, derived from the second and third pharyngeal pouches in the latter. In snakes there are usually two pairs derived from the

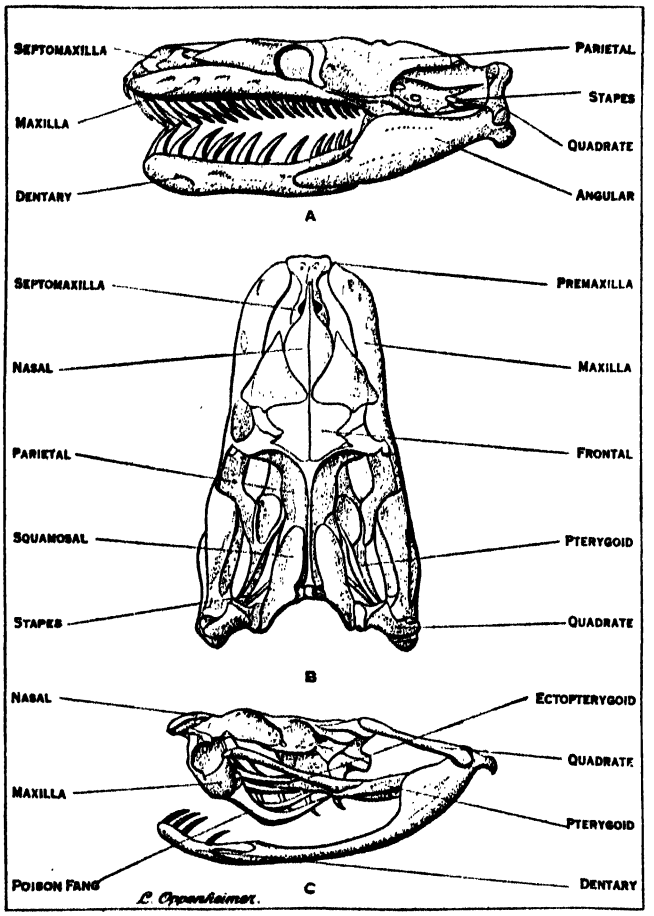

FIG. 19.—(A) SKULL AND LOWER JAW OF PYTHON (NON-POISONOUS). (B) SAME FROM ABOVE. (C) LEFT SIDE OF SKULL AND LOWER JAW OF RATTLESNAKE (POISONOUS)

dorsal extremities of the fourth and fifth pouches. A variable series of epithelial bodies, either dorsal or ventral, is present, and there is an ultimobranchial body of the left side, at any rate, in lizards.

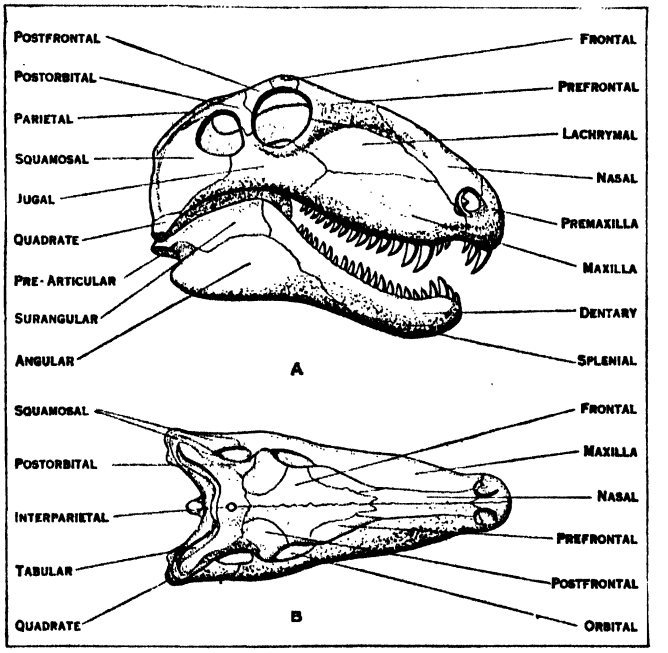
Nervous System: *Sense Organs.*—Skin. Tactile corpuscles are found in the cutis of all reptiles. In crocodiles a group of them lies at the bottom of a pit, filled with non-conified cells near the anterior border of each of the large ventral scales. In Chelonia they lie in the thin layer of connective tissue between the epidermal scutes and the bony shell. In certain Agamids some of the scales of the dorsal surface bear long rod-like projections and are surrounded by nerve endings so that they may function as specialized tactile organs as do some mammalian hairs.

Taste.—It is clear that some sense of taste exists, the taste buds being probably on the tongue.

Smell.—The sense of smell is well developed in all recent reptiles, although it was much reduced or absent in the later Pterodactyls.

The external nostril, often provided with a valve, leads into a short vestibule, which opens out into the true olfactory chamber, whose wall is lined with the sensory epithelium which contain the olfactory cells. The area of the surface of this epithelium is increased by the presence of a ridge, the concha, which stretches into the cavity from the outer side. In crocodiles there is an additional concha, and there are reasons for believing that in Cynodonts, ethmo- and naso-turbinals were developed as in mammals. The nasal cavity finally opens to the palate by the internal nostril, which may be carried far back by the formation of a secondary palate.

Jacobsen's organ is, in Chelonia, a mere diverticulum of the ventral part of the nasal cavity. In Squamata it becomes an independent chamber, separated from the nasal cavity by the septomaxillary bone; it then has a special opening to the palate and may be very highly developed, receiving a large proportion of the olfactory nerve fibres. Its function is clearly to smell food after it has been taken into the mouth.



Jacobsen's organ soon vanishes in crocodiles. A special nasal gland is developed in the concha of reptiles, and the naso-lachrimal duct opens on the lateral wall of the nasal cavity.

Eye.—The eyes of reptiles are normally provided with movable upper and lower eyelids, and a nictitating membrane which is usually transparent and can be drawn across the cornea. The nictitating membrane may vanish in some lizards; in snakes it is permanently drawn across the eye, fuses with the remnant of the upper eyelid, and has a cornified scale on its outer surface, which is shed with the rest at ecdysis.

In some desert lizards the lower eyelid has a transparent window in the middle and is fused with the upper. In chameleons there is no nictitating membrane, and the upper and lower eyelids fuse, leaving only a small hole the size of the pupil. There are Harderian, conjunctival and lachrimal glands, whose secretion is discharged into the nose and palate by the naso-lachrimal duct.

The sclerotic coat of the eye ball often contains a ring of supporting ossicles, the cornea is convex. The crystalline lens is supported in a capsule by ciliary muscles, and accommodation can be carried out over a wide range.

The iris is usually brightly-coloured, and the pupil can contract either to a circular or a slit-like condition. The pupilary reflex to light is usually difficult to evoke. The retina is built up of

FROM "CONTRIBUTIONS FROM THE WALKER MUSEUM, CHICAGO UNIVERSITY"

FIG. 20.—SKULL OF THE PELYIOSAUR, SPHENACODON: (A) RIGHT SIDE, WITH LOWER JAW, (B) FROM ABOVE

small elements, both rods and cones being present in some forms, rods or cones alone in others. The retina, like that of birds, often contains pigmented oil granules, yellow, red, green, and, in Chelonia, blue and violet. Nutrition of the contents of the eye ball is secured, in many reptiles, by the presence of a pecten, a pigmented vascular projection, at first conical and when more highly developed fanshaped which arises from the fundus. A pecten is absent in Sphenodon and rudimentary in Chelonia. In snakes its place is taken functionally by a vascularization of the choroid. In chameleon there is a macula and fossa like that of

birds or primates. The eyes of reptiles are always laterally directed, but can be moved through a small arc of about 20°. They possess the normal series of six eye muscles and a retractor bulbi in addition. Reptiles appear to possess a colour sense, but accurate observations are lacking.

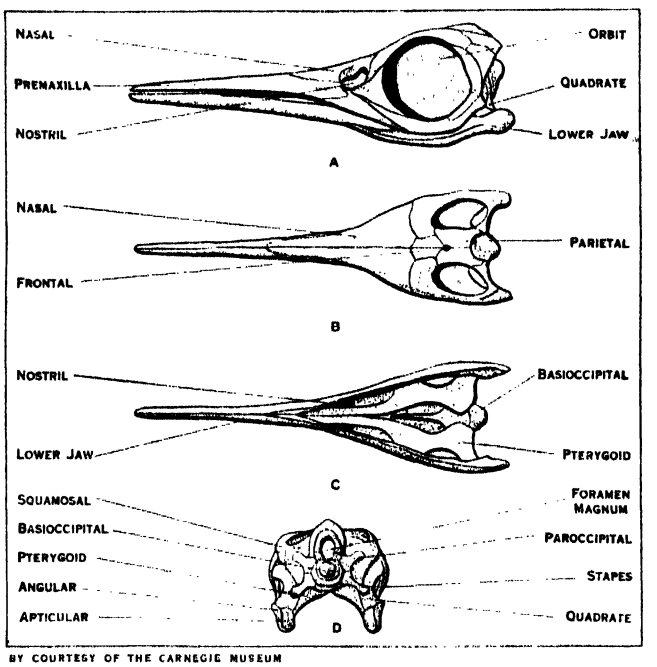
Pineal Eye.—In Sphenodon and lizards the epiphysis of the brain lies in a foramen between the parietal bones, and is covered by a transparent scale. It ends in a vesicle whose outer wall is lens-shaped, whilst the lower surface is a pigmented retina. It appears to exhibit no perception of light. The immense size of the pineal foramen in some fossil reptiles suggests that the pineal eye was functional in them.

Ear.—All reptiles have an inner and middle ear, an outer ear being present in crocodiles and the extinct Cynodonts. The inner ear is more advanced than that of Amphibia in that the utriculus is connected to the swollen sacculus by a duct from which the endolymphatic duct rises. There is a lagena which, in crocodiles, becomes much elongated and provided with a rudimentary organ of Corti seated on a basilar membrane.

The endolymphatic duct ends blindly, usually within the skull, but in Geckos is extended into à sac under the skin of the neck. There is a special perilymphatic duct which forms a closed tube definitely associated with the lagena. In crocodiles this begins to form definite scalae comparable to those of the mammalian cochlea.

The cavity of the middle ear is formed by an upgrowth from the first visceral pouch; in Sphenodon and lizards the cavity communicates with the pharynx by a wide opening, in Chelonia by a narrow Eustachian tube. In crocodiles the Eustachian tubes of the two ears meet and form a duct running in a special canal between the basisphenoid and basioccipital to open in the middle line just behind the choanae; lateral branches from the duct pass in canals between the basisphenoid and the pterygoids up into the supraoccipital and cranial roof, there enlarging into air spaces which again communicate with the tympanic cavities. Finally, a tube rising from each cavity leads air down into the quadrate and lower jaw. The history of this elaborate arrangement can be made out from fossil materials. In snakes, the tympanic cavity is totally obliterated. The outer wall of the tympanic cavity is the tympanic membrane, which, in crocodiles and most lizards, is a thin sheet sunk below the surface of the head at the lower end of an external auditory meatus. In Sphenodon and Chelonia it lies flush with the surface, and its outer surface is indistinguishable from that of the neck. In snakes and chameleons it is absent.

The tympanic membrane is connected with the fenestra ovalis by a rod, whose inner end is an ossified columella or stapes, whilst the unossified outer end is the extra columella. This is small and simple in Chelonia, absent in snakes, where the end of the stapes articulates with the quadrate, and in Amphisbaenans. In lizards, the extra columella has a dorsal process attached to the end of the paroccipital process, and often detached, a ventral process applied to the quadrate, and a plate for insertion in the tympanic membrane. The whole structure is of hyoidean origin, and the hyoid articulates with the end of the paroccipital process. In Sphenodon it fuses with the end of the extra columella, and in crocodiles it arises from its shaft to pass down the air canal to the lower jaw and become continuous with Meckel's cartilage.



Most or all reptiles are capable of hearing, but we know nothing of their ability to discriminate musical notes.

Peripheral Nervous System.—The spinal nerves of reptiles agree in all important characters with those of other Tetrapods, the only interesting peculiarity being the presence in snakes of rudimentary pectoral and pelvic plexuses, relics of the limbs of their ancestors.

The sympathetic system presents an advance over that of most Amphibia in that many of the ganglia in the thoracic region are fused into a single large ganglion, and that the cervical sympathetic is separated into deep and superficial portions, each running continuously from the ganglion of the vagus to the thorax, the details varying in different orders. This arrangement is derived from that of Urodeles and leads directly to birds.

The cranial nerves of reptiles differ from those of living Amphibia in the absence of all trace of the lateral line system, except the auditory nerve, in the presence of a spinal accessory nerve XI. and in the fact that the hypoglossal nerve XII. passes out through the exoccipital bone.

Brain.—The reptilian brain is larger proportionately than that of an amphibian of the same size. The cerebral hemispheres

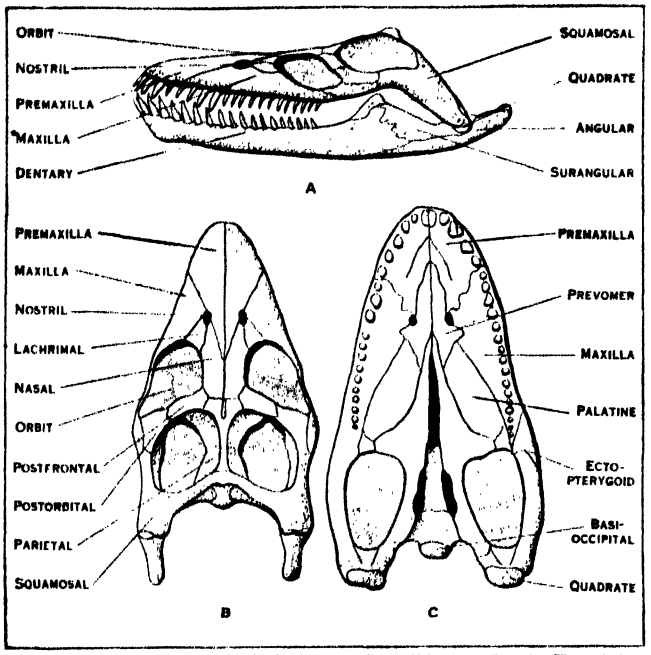
BY COURTESY OF THE CARNEGIE MUSEUM

FIG. 21.—SKULL AND LOWER JAW OF THE ICHTHYOSAUR OPHTHALMOSAURUS; (A) LEFT SIDE, (B) FROM ABOVE, (C) FROM BELOW

are pointed and usually pass gradually into the olfactory lobes. Their hinder ends are free and often project posteriorly so as to conceal the diencephalon.

In Sphenodon and in Chelonia the whole of the upper surface of the hemisphere, from the hippocampus on the inner surface to the lateral face, is covered by a pallium, devoted to the sense of smell. This layer of cells then turns inward from the surface, and lies on the top of the corpus striatum, forming a hypopallium. In lizards, and especially in crocodiles, the dorsal surface of the hemisphere becomes less and less nervous until, in birds, it is a mere membrane playing no part in the functioning of the brain. In these reptiles the hypopallium becomes broken up by a penetration of nerve fibres, loses its pallial appearance and becomes assimilated to the corpus striatum. Thus, presumably in these animals, and certainly in birds, behaviour is controlled and memory exercised by a part of the brain quite different from that which fulfils these functions in mammals. In some reptiles, at any rate, the first trace of the neopallium, which is the important and developing part of the brain in mammals, is represented by a small cortical area in which alone other senses than smell gain a direct representation.

The mid brain of reptiles has its roof thickened and raised into a pair of optic lobes, which not only receive the endings of the optic nerves from the retina but are the motor area, stimulation of which brings about movements of the body.



The cerebellum of reptiles is always larger and better developed than that of Amphibia, though in living forms it is not externally divided into regions, as is that of a bird or mammal.

The brain of the extinct pterodactyls is interesting because, in the reduction of the olfactory lobe, the large size of the cerebellum and the lateral position of the optic lobes, it exactly resembles that of a bird, is indeed more like that of recent birds than is the brain of Archaeopteryx, which is the most primitive member of that class.

Reproduction.—Fertilization of the reptilian egg always takes place internally, in contrast to the condition in many Amphibia.

The egg is always large and provided with so large a store of food materials in the form of yolk that the growing embryo, without any additional materials, can hatch in a form capable of fending for itself, and is, indeed, usually a miniature copy of its parents.

This ovum is surrounded by a semi-fluid layer of albumen, and enclosed in a membranous shell which may be calcified as is

FROM THE CATALOGUE OF MARINE REPTILES OF THE OXFORD CLAY, BY COURTESY OF THE BRITISH MUSEUM

FIG. 22.—SKULL OF THE PLESIOSAUR, MURAENOSAURUS
A. From the left side, B. from above, C. from below

that of a bird. Usually the egg is laid before development has gone far, but in some cases it is retained within the oviduct until the foetus is ready to be born. These animals, including many lizards and snakes, are thus viviparous. In their case the egg shell is thin, and food materials may pass through it; indeed, in some cases it is practically absent, and the little lizard secures nourishment from its mother through a special placenta.

Cleavage is meroblastic, resulting only in the formation of a primitive plate of cells. Gastrulation involves an actual invagination, resulting in the formation of an archenteron which has both floor and roof. The process is, indeed, similar in principle to that in the Gymnophionan Amphibia. No primitive streak is formed behind the blastopore in Chelonia, Sphenodon, lizards or snakes.

The later development much resembles that of birds or monotremes. A headfold is formed, followed by tail and lateral folds, which gradually raise the embryo from the yolk and extra-embryonic structures. An amnion arises from the extra embryonic somatoplear joint, as in birds, and an allantois is formed later by a ventral outpushing of the hind gut. It serves not only as a reservoir for the excretory products of the embryo, but also as a respiratory organ. The embryo breaks its way out of the shell by the aid either of an egg-tooth, placed mesially on its nose or of a caruncula on its head.

Further details will be found in the article VERTEBRATE EMBRYOLOGY.

Mode of Life.—No general statements can be made about the habits of reptiles. If the extinct forms be taken into account it will be found that they have occupied all the habitats which are to-day filled with mammals, except that they are excluded from polar regions by the impossibility of hatching their eggs there, and in extreme cases of achieving a sufficiently high rate of metabolism. The temperature of the body of reptiles, like that of Amphibia, and unlike that of the birds and mammals, is determined by that of their surroundings, rising when the animal is in a warm place, and sometimes becoming very high in bright sunlight, and falling at night, perhaps to freezing point. The animal's muscular activity always keeps it a very few degrees above the air temperature. Some idea of the variety of habit of reptiles may be gathered from the section on *Locomotion* in this article, and further facts from the articles: LIZARD, TORTOISE, CROCODILE, SNAKE and SPHENODON.

Geographical Distribution.—Apart from the limitation imposed by temperature, no general statements can be made about reptilian distribution; any useful account would occupy much space, and involve a discussion of the interrelationships of the families of lizards and snakes, a disputed field.

Geological Distribution.—The earliest bone which has been referred to a reptile is an isolated femur from the Lower Carboniferous of Scotland. Eosauravus, from the Upper Carboniferous (Middle Coal Measures) of Ohio, is probably a reptile, and Solenodonsaurus, from the top of the Upper Carboniferous of Czechoslovakia is certainly one.

The evolution of the reptiles was rapid, nearly all orders being fully established by the end of Triassic times. Several important orders became extinct at the end of the Trias, but the reptiles were the dominant group of verfebrates to the end of the Mesozoic, when, within a short period though not simultaneously, many orders became extinct, leaving only the four which still survive.

Economic Importance.—Reptiles are of slight importance to man. Poisonous snakes are responsible for many deaths of man and domesticated animals in all tropical and some temperate regions.

The marine turtle, *Chelone midas*, found in tropical waters of the Atlantic, Indian and Pacific oceans, provides the best of all soups; several other forms found in fresh water are often eaten, the most familiar of these being the terrapins, of the genus *Chrysemys*. The eggs of various species are also eaten by uncivilized peoples.

The skins of crocodiles, and of certain of the larger lizards and snakes, are tanned and used as leather. This consists only of the cutis, the horny epidermis being removed. This leather is extraordinarily tough and wear resisting, and the presence in it of the papillae which underlie the scales gives it a most attractive surface. The pigment, or at any rate such of it as

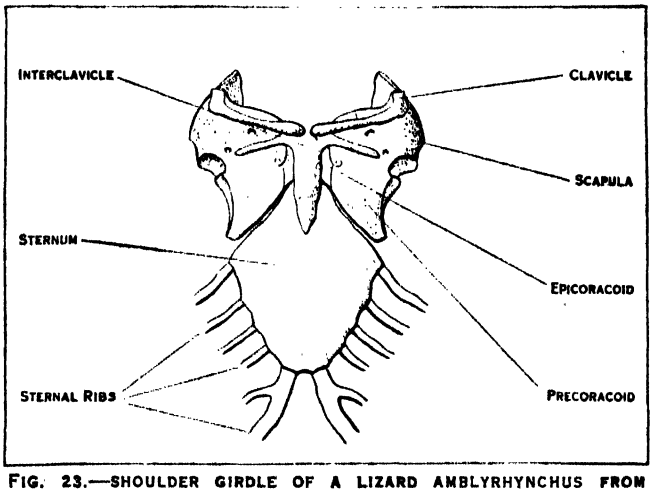


FIG. 23.—SHOULDER GIRDLE OF A LIZARD AMBLYRHYNCHUS FROM BELOW, SHOWING THE RELATIONS OF THE CLAVICLES, INTERCLAVICLE PRECORACOID AND STERNUM TO ONE ANOTHER

is melanine, may remain in the leather and give it characteristic patterns. The use of reptilian leathers for ladies' shoes and handbags has become popular and led to the destruction of many of these animals. That of alligators, however, is derived in part from animals bred for the purpose.

Further information about reptiles will be found in the separate articles: CROCODILE, DINOSAURIA, LIZARD, SNAKE, SPHENODON, ICHTHYOSAURUS, PLESIOSAURUS, PTERODACTYL, TORTOISE, etc., and in the general articles, EMBRYOLOGY, ANATOMY, PHYSIOLOGY, NEUROLOGY, ZOOLOGICAL DISTRIBUTION, etc. (D. M. S. W.)

REPTON, a village in Derbyshire, England, 8 m. S.W. of Derby, on the L.M.S. railway. Pop. (1921) 1,929. Its famous school was founded in 1557 by Sir John Port. Its modern buildings incorporate considerable portions of an Augustinian priory established in 1172. There was an ecclesiastical establishment on this site in the 7th century, the first bishop of Mercia being established here. The existing parish church of St. Wystan retains pre-Conquest work in the chancel.

REPUBLIC, a state in which the supreme power rests in the people, or in officers elected by them, to whom the people have delegated powers sufficient to enable them to perform the duties required of them. In the small republics of antiquity the people usually expressed their preferences directly, but in the larger republics of modern times representatives are elected to sit in law-making bodies. The head of the state is usually elected directly, and in modern usage this fact distinguishes a republic from a monarchy in which the head is hereditary.

In the ancient world of Greece and Rome the franchise was in the hands of a minority, who were surrounded by, and who governed, a majority composed of men personally free but not possessed of the franchise, and of slaves. Modern writers have often used the literal translation of the Latin *respublica*, as meaning only the state, even when the head was an absolute king, provided that he held his place according to law and ruled by law. "Republic," to quote one example only of many, was so used by Jean Bodin, whose treatise, commonly known by its Latin name *De Republica Libri Sex,* first appeared in French in 1577. Englishmen of the middle ages habitually spoke of the commonwealth of England, though they had no conception that they could be governed except by a king with hereditary right. The coins of Napoleon bear the inscription *"République française, Napoléon Empereur."* Except as an arbitrary term of art, or as a rhetorical expression, "republic" has, however, always been understood to mean a state in which the head holds his place by the choice of his subjects. Poland was a republic because its king had in earlier times to be accepted, and in later times was chosen by a democracy composed of gentry. Venice was a republic, though after the "closing of the great council" the franchise was confined to a strictly limited aristocracy, which was itself in practice dominated by a small oligarchy. The seven states which formed the confederation of the United Netherlands were republics from the time they renounced their allegiance to Philip II., though they chose to be governed by a stadtholder to whom they delegated large powers, and though the choice of the stadtholder was made by a small body of burghers who alone had the franchise. The varieties are many. What, however, is emphatically not a republic is a state in which the ruler can truly tell his subjects that the sovereignty resides in his royal person, and that he is king, or tsar, "pure and absolute," by the grace of God, even though he may hasten to add that "absolute" is not "despotic," which means government without regard to law. The case of Great Britain, where the king reigns theoretically by the grace of God, but in fact by a parliamentary title and under the Act of Settlement, is, like the whole British constitution, unique.

There is in fact a fundamental incompatibility between the conceptions of a government as a commonwealth and as an institution based upon a right superior to the people's will. Where these two views endeavor to live together either the ruler will confiscate the rights of the community to himself or the community, acting through some representative body, will confine the head of the government to defined functions.

The conception of a republic in which all males, who do not belong to an inferior and barbarous race, share in the suffrage is one which would never have been accepted in the ancient or mediaeval world, for it is based on a foundation of which they knew nothing,—the political rights of man. When the Scottish reformer John Knox based his claim to speak on the government of the realm on the fact that he was "a subject born within the same" he advanced a pretension very new to his generation. But it was one which was fated to achieve a great fortune. The right of the subject, simply as a member of the community, to a voice in the community in which he was born, and on which his happiness depended, implied all "the rights of man" as they were to be stated by the American Declaration of Independence, and again by the French in 1789. They could be vindicated only by revolt against monarchical governments in the old world and the new. They were incompatible with all the convictions which make monarchy possible as they embodied themselves in the modern democratic republics of Europe and America. It is a form of government not much more like the republic of antiquity and the middle ages than the French *sansculottes* was like Harmodius and Aristogeiton, whom he admired for being what they most decidedly were not—believers in equality and fraternity. But it does, subject to the imperfections of human nature, set up a government in which all, theoretically at least, have a voice in what concerns all.

One of the major results of the World War was the discrediting of monarchical government in many European States. There swept over Europe a desire on the part of people for self-government which led to the adoption of republican forms of government by a number of previously monarchical states. As early as March 12, 1917, when the Emperor Nicholas II. abdicated, the Russian people began the conferences that led to the formation of the U.S.S.R. For analysis of this form of government *see* the articles UNION OF SOCIALIST SOVIET REPUBLICS and RUSSIA.

Germany became a republic on Nov. 9, 1918, on the announcement of the abdication of the Emperor William II. The president is elected by direct vote of all the citizens over 20 years of age regardless of sex, and the members of the legislature are chosen by universal suffrage on the proportional system. (*See* GERMANY.) Three days later the Austrian Republic was declared, and on Nov. 10, 1920, the new Constitution drawn up by the National Constitional Assembly went into effect. (*See* AUSTRIA.)

On Nov. 14, 1918, the National Assembly of Czechoslovakia proclaimed the republican Czechoslovak State. The constitution passed Feb. 29, 1920, provided a Senate elected by a vote of all citizens over 26 years of age and a Chamber of Deputies elected by vote of all citizens over 21 years of age. (*See* CZECHOSLOVAKIA.) Between 1918 and 1925, in the order named, Finland, Estonia, Poland, Latvia, Lithuania, Turkey and Greece declared themselves to be republics. For details of franchise and representation *see* under separate articles.

REPUBLICAN PARTY, THE, in the United States was organized in 1854. In 1860, it elected its first president, Abraham Lincoln, and since that time, in a very large measure, has directed the political history of the country. In the 68 years (1861–1929) a Republican president has been in office all but 16 years, and in Congress the party has been in the majority in the Senate all but 12 years and in the House all but 22 years. The Republican Party has emphasized *nationalism*, first as against the doctrine of sectionalism and possible secession, later as against what is generally termed *internationalism*. A cardinal principle of its creed is the protective tariff. To the credit of its leadership are the first trans-continental railway and the Panama canal; the acquisition of all U.S. possessions abroad; promulgation of the "open door" oriental policy; the maintenance of financial stability. It opposed entrance into the League of Nations, and opposes adherence to any form of super-government. Since the World War, under its leadership, the United States has established a record for payment of national debt unequalled by any country in the world's history, and for rigorous economy in governmental management.

Origin.—Intense opposition in non-slave States to the further extension of the slavery system, and the breakdown of the compromise policy of Clay, with the Kansas-Nebraska bill and repeal of the Missouri Compromise as the incidental causes, brought the Party into being. The first actual meeting was possibly the one at Ripon, Wis., Feb. 28, 1854. The first convention was held at Jackson, Mich., July 6, 1854. All opposed to slavery extension were welcome. An informal gathering, national in scope, meeting in Pittsburgh Feb. 22, 1856 planned the first national convention which assembled in Philadelphia, June 17. The chairman, E. D. Morgan of New York, declared the party's purpose to be to determine "not whether the South is to rule or the North . . . but whether the broad national policy our fathers established, cherished and maintained is to be permitted

to descend to her sons." Opposition to slavery extension and to polygamy, the imperative necessity of a railroad to the Pacific ocean, and approval of Congressional appropriations for improvement of rivers and harbours, were the platform subjects. Gen. John C. Frémont, of California, and William L. Dayton were the nominees, but were defeated after a vigorous campaign. Many events rapidly consolidated and intensified the anti-slavery movement, and on May 16, 1860, probably the most historic of all Republican national conventions assembled in the "wigwam" at Chicago. It established a majority rule for nominations in contrast to the Democratic two-thirds. Threats of secession were denounced by the platform, which favoured restriction of slavery, opposed re-opening the slave trade, and favoured a protective tariff. Abraham Lincoln was elected president, Hannibal Hamlin vice-president. The story of the Lincoln administration is very largely the story of the Civil War. Preservation of the Union at any cost was Lincoln's policy, and emancipation and other policies were largely incidental. In the midst of war, however, the party found time to establish in 1862 a national currency through a national banking system; to pass a high tariff law and internal revenue acts; and to begin construction of the first transcontinental railway. Despite earlier doubts, due to opposition to the extent of the war and its terrific cost in life, President Lincoln was re-nominated by acclamation and re-elected in 1864, Andrew Johnson, of Tennessee, being selected as vice-president to secure the border States' support. The war was continued to a successful conclusion, but the assassination of Lincoln on April 14, 1865, quickly terminated the celebrations of victory.

Reconstruction.—Johnson's outstanding problems, and those of the two following administrations, had to do with the so-called "reconstruction" of the seceded States. A marked difference of opinion as to the treatment to be accorded these States developed. Johnson's policy was not rigorous to the extent demanded by powerful Congressional leaders. The result was a contest between the Executive and Congress, culminating in Johnson's impeachment and acquittal by one vote. Before he went out of office, Congress submitted the 14th and 15th amendments.

"Let us have peace" was the slogan under which Gen. Ulysses S. Grant was elected president in 1868, with Schuyler Colfax of Indiana as vice-president. The problems of reconstruction, enactment of bills designed to enforce provisions of the 14th amendment and paving the way for a national civil service, together with the Senate's refusal to ratify a treaty to annex Santo Domingo, were outstanding features of Grant's administration. In 1872, certain Republicans opposed Grant's re-election, and a liberal Republican party nominated Horace Greeley to run against him. The Democratic national convention endorsed Greeley, but only six States were carried by the fusion ticket. Despite two troublesome years, with panic and scandal, there was much of credit in constructive achievement and the U.S. foreign policies won especial respect abroad. In 1874, President Grant vetoed an inflation bill and a year later approved the resumption of specie payments. Economy and lower taxes were emphasized.

Making capital out of scandals and with the slogan, "Turn the rascals out," the Democratic party won the House in 1874 and almost won the presidential election of 1876. Rutherford B. Hayes, of Ohio, Republican nominee for president, won after an electoral commission, especially created, had decided one of the most bitter political contests. William A. Wheeler, of New York, became vice-president. President Hayes completed "reconstruction" in the South by withdrawing Federal troops, a policy which brought him Northern criticism because immediately after the troops were withdrawn Democratic leaders in Southern States inaugurated the policy of negro disfranchisement. Specie payments were resumed. Chinese immigration was restricted.

Domestic Questions.—James A. Garfield, of Ohio, was elected president in 1880, and upon his assassination in 1881, Chester A. Arthur, of New York, succeeded. A further extension of civil service laws, establishment of the Department of Labour, two-cent first class postage rates, the beginnings of a new navy and steps looking toward an inter-oceanic canal were brought about. The campaign of 1884 was most bitter in personal recriminations, both nominees, James G. Blaine, Republican, and Grover Cleveland, Democratic, suffering unparalleled attacks. Certain Republican elements refused to support Blaine, and at the end, one famous sentence, "Rum, Romanism and Rebellion," lost for him the State of New York by 1,149 votes and so lost the electoral college. In 1888, Benjamin Harrison, of Indiana, defeated Cleveland, and Levi P. Morton, of New York, became vice-president. The tariff was a chief issue, but enactment of a higher rate bill, known as the McKinley Act, was delayed until just before the election of 1890. As a result, the country did not have time to correctly appraise its effects and an overwhelming Republican defeat followed. The Harrison administration was noted for enactment of the Sherman anti-trust laws, additional coinage of silver, admission of several new States, among them Wyoming with the first provision for woman suffrage, and the famous Reed enforcement of new rules in the House designed to prevent minority obstruction. Personal dislike of the president by certain prominent leaders was a large factor in bringing about Harrison's defeat for re-election in 1892, when Cleveland was returned to office with his party in control of both Houses of Congress for the first time since the Civil War. A drastically lower tariff bill was enacted; one of the worst panics and unemployment periods in U.S. history occurred. This made the tariff a major issue for the campaign of 1896, but as this battle approached, much greater prominence was given the question of the coinage of silver in relation to gold. William McKinley, of Ohio, was nominated by the Republicans on a gold standard platform, with Garrett A. Hobart, of New Jersey, vice-president. William Jennings Bryan, of Nebraska, won the Democratic nomination and stood upon the issue of the free coinage of silver at the ratio of sixteen to one. McKinley won. Soon after he took office, enactment of higher protective rates in the Dingley bill was followed by a tremendous revival of business and general prosperity.

Expansion Abroad.—The outstanding event of the McKinley administration, however, was the war with Spain over Cuban liberation. Resulting from this, the United States acquired the Philippines, Porto Rico, Guam and other possessions; Hawaii was annexed. The policy of continental isolation necessarily came to an end with this expansion, and citizens of the United States began to take an interest in problems abroad. With McKinley's assassination, after his re-election, Theodore Roosevelt, of New York, became president, and he was also the successful candidate in 1904. One of the most popular and vigorous men ever in the presidency, Roosevelt's administration was characterized by the policies: strong emphasis on conservation of national resources; beginning of the Panama canal; enactment of pure food and meat inspection legislation; legislation enlarging the functions of the interstate commerce commission so it could regulate railway rates against discriminatory practices; settlement of the anthracite coal strike; intervention to bring peace in the Russian-Japanese war; creation of a monetary commission; sending the American fleet around the world. Seldom has a president or an administration had a hand in so many issues that appealed so generally to the people.

William Howard Taft, of Ohio, was elected president in 1908, and James S. Sherman, of New York, vice-president. A new tariff law failed to appeal to the people as making good party pledges for lower rates, and a Democratic House was elected in 1910. The House was the scene of a so-called war against Cannonism, with modified powers for the speaker resulting. The 16th amendment to the Constitution, making possible a national income tax law, was submitted, and the parcel post system established. A division of the party came between the followers of Roosevelt and Taft in 1912, and the formation of the Progressive party with Roosevelt as leader brought about the election of Woodrow Wilson, Democratic candidate for president in 1912. His party won control of both houses of Congress and retained it for four years for the first time since 1860. A lower tariff bill

was enacted and new banking laws creating the Federal Reserve system.

The World War.—The World War occupied the attention of the world 1914 to 1918. The rallying cry, "he kept us out of war" proved sufficient to re-elect Wilson in 1916, but soon thereafter it was apparent that this campaign slogan was not prophetic, as the people had believed. The Republicans, while losing the presidency in 1916, won the House, but when President Wilson asked for the participation of the United States in the war in 1917, Republicans vied with Democrats in support of the war programme. An appeal by the President for a Democratic Congress in 1918 startled and angered the country, resulting in Republican control of both Houses by large majorities in the 66th Congress. The President did not appear to regard this as a rebuke of his personal leadership but went abroad and participated in the treaty negotiations at Versailles, his influence incorporating in the treaty provisions for a League of Nations. The Covenant of the League was considered by numerous leaders, some Republicans, some Democrats, as failing to protect American interests, but proposed clarifying reservations were refused by President Wilson. A long fight resulted, and the issue was projected into the campaign of 1920. The result was a great Republican victory, electing Warren G. Harding, of Ohio, president, and Calvin Coolidge, of Massachusetts, vice-president.

President Harding's administration made a separate treaty of peace with Germany and Austria, summoned a naval arms conference resulting in an international agreement limiting naval construction, made vast reductions in government personnel, established the budget system, and placed strong emphasis on the utmost national economy. Loans were made to relieve farm depression. A debt commission was appointed to adjust World War loans to foreign nations. Higher tariff legislation was enacted. President Harding made the first visit to Alaska ever made by an American president in Aug. 1923, but died very suddenly on his return. Calvin Coolidge succeeded him, and in 1924 was nominated and elected, with Charles G. Dawes, of Illinois, as vice-president. This administration was especially noted for its insistence upon rigid economy and payment of the national debt. There was widespread business development, which had been fostered and encouraged by the administration's policy. The president's proposal for adherence to the World Court was approved, but the United States has not become a member, as reservations insisted upon by Congress have not been accepted by the Court. The party was the victim of unfortunate scandals, in connection with what are known as the Tea Pot Dome oil leases, carried out by Albert B. Fall, secretary of the interior under President Harding. President Coolidge enjoyed the widespread confidence of his countrymen, but when urged to run for re-election in 1928, he announced that he "did not choose to run for President in 1928." When efforts to "draft Coolidge" failed there was a widespread movement toward Herbert Hoover, secretary of Commerce in the Coolidge administration, a movement which the president approved of although he made no actual pronouncement to that effect previous to the meeting of the Republican Convention. Hoover was nominated and carried the party to victory by an electoral majority unprecedented in Republican history. For the first time since the Civil War, Virginia, North Carolina, Florida and Texas, of the hitherto solidly Democratic South, were found in the Republican column. Hoover entered office on March 4, 1929.

REQUEST, LETTERS OF. The legal terms "letters rogatory," or "of request" (*commission rogatoire*), express a request made by one judge for the assistance of another in serving a citation, taking the deposition of a witness, executing a judgment, or the doing of any other judicial act. The only trace of such a practice to be found in England or the United States, independent of statutory enactment, is in the admiralty doctrine that the sentence of a foreign court of admiralty may be executed on letters of request from the foreign judge or on a libel by a party for its execution. *See* the authorities collected by Sir R. Phillimore in *The City of Mecca*, 5 P.D. 28. The British and United States courts issue commissions to private persons, generally, however, to consular officers, but sometimes to foreign judges in their private capacities, for the purpose of taking the depositions of witnesses. Many countries object to this process and require letters of request, which have to be forwarded through diplomatic channels (see *Rules of the Supreme Court*, O.37). In ecclesiastical law, letters of request are issued for the purpose of sending causes from one court to another. Letters of request are also issued for other purposes: to examine witnesses who are out of the jurisdiction, to enforce a monition, etc.

REQUESTS, COURT OF, originally a committee of the king's council in England. Petitions of poor persons were heard by the justices in eyre and on the fall of the eyre were referred by the council to the chancery. By an Order in Council of 1390 these petitions were transferred to a committee of the council and the lord privy seal became its president. At first the court followed the king, but about 1516 Wolsey assigned to it a permanent seat in Whitehall, when it became known as the court of Whitehall or the court of poor men's causes. Lastly, it obtained its official title of the court of requests. The judges were at first those privy councillors who happened to be present, together with judges and masters as assessors. Eventually four privy councillors, known as masters of requests, were appointed at fixed salaries.

See I. S. Leadam, *Select Cases in the Court of Requests* (Selden Society, 1898).

REQUISITION OF SHIPPING: *see* SHIPPING, MINISTRY OF; SHIPPING CONTROL COMMITTEE.

REREDOS (rēr'dŏs), an ornamental screen of stone or wood built up, or forming a facing to the wall behind an altar in a church. Reredoses are frequently decorated with representations of the Passion, niches containing statues of saints, and the like. In small churches the reredos is usually replaced by a hanging or parament behind the altar, known as a dossal or dorsal. (*See* also ALTAR.) For the legality of images on reredoses in the Church of England, *see* IMAGE.

RESACA DE LA PALMA, a battlefield of the War between Mexico and the United States (1846–48), about 4 m. N. of Brownsville, Texas. On the morning of May 9, 1846, the day after the battle of Palo Alto, which had been indecisive, the United States' troops under Brig. Gen. Zachary Taylor, ready to renew the conflict, were surprised to see the column under the Mexican Gen. Arista disappearing through the *chaparral* toward Matamoras. Unable to pursue with more than a few hundred men, because he must first put his wagon train in a state of defence, Taylor was slow in following his adversary. The latter had entered a dense growth that continued interruptedly to the Rio Grande, 7 m. to the south.

After having marched about half-way through the thickets, Arista disposed his command behind an old river channel which crossed the road at right angles. The bed (Resaca de Guerrero) was full of ponds and mud, impassable in many places. The Americans, about 1,700, came upon the Mexican guns planted in the road and almost immediately thereafter there was a collision. The dense growth of mesquite and cactus made it impossible for companies to see each other and it was difficult for Taylor's artillery to operate. His soldiers, losing touch with one another, floundered and hacked their way toward their enemy. Although there was little direction or plan to the encounter, the discipline and training of his subordinates kept them pressing forward. The vigour of the U.S. troops in their assault dismayed the Mexicans. When one of Arista's flanks was accidentally turned, a panic seized his whole force. It is estimated that about 4,000 out of some 5,000 succeeded in reaching the river where many were drowned in crossing. The American loss was comparatively small.

RESCHEN SCHEIDECK. This Alpine pass is in a way the pendant of the Brenner Pass, but leads from the lower Engadine to the upper valley of the Adige. Near the summit (4,902 ft.) is the hamlet of Reschen, while some way below is the former hospice of St. Valentin auf der Haid, mentioned as early as 1140. Starting from Landeck, the motor road runs up the Inn valley to Pfunds, whence it mounts above the gorge of Finstermünz to the village of Nauders (27½ m.) joining the road from the Swiss Engadine (53½ m. from St. Moritz). Thence it mounts gently to the pass, and then descends, with the Adige, to Mals (15½ m.), whence the pass is sometimes wrongly named Malserheide. The road now descends the upper Adige valley, or Vintschgau, past Meran (37½ m.) to Botzen (20 m. from Meran) where the Brenner route is joined.

RESEARCH, INDUSTRIAL. Industrial research aims at applying to industry the truths wrested from nature by workers in science. In 1893 Sir W. Anderson wrote "The days are past when an engineer can acquit himself respectably by the aid of mother wit alone or of those constructive instincts which in the past led our predecessors to such brilliant results." Each year makes the truth of his words more manifest; industrial research is one important stone in the foundation of our modern civilization.

But appreciation of this truth has been slow of growth, at any rate in England. In Germany during the later years of the 19th century the Reichsanstalt and the Materials Prüfungs Amt were founded, and their work, along with investigations at technical institutes, had no small effect on German industry. The beginning of the 20th century saw the establishment of the National Physical Laboratory in Great Britain, followed almost immediately by that of the Bureau of Standards at Washington, while in Paris there was the Laboratoire Central d'Électricité and much renewed activity at the Laboratoire d'Essais in the Conservatoire des Arts et Métiers. But it needed the shock given by the World War before the truth of Sir W. Anderson's words was fully grasped.

Industrial research does not necessarily differ from so-called pure research in its methods; it is the object with which the investigation is made that constitutes the difference; and of course much work is necessary before the laboratory discovery, or the brilliant intuition of the inventor, verified by striking experiments, can be translated into the practice.

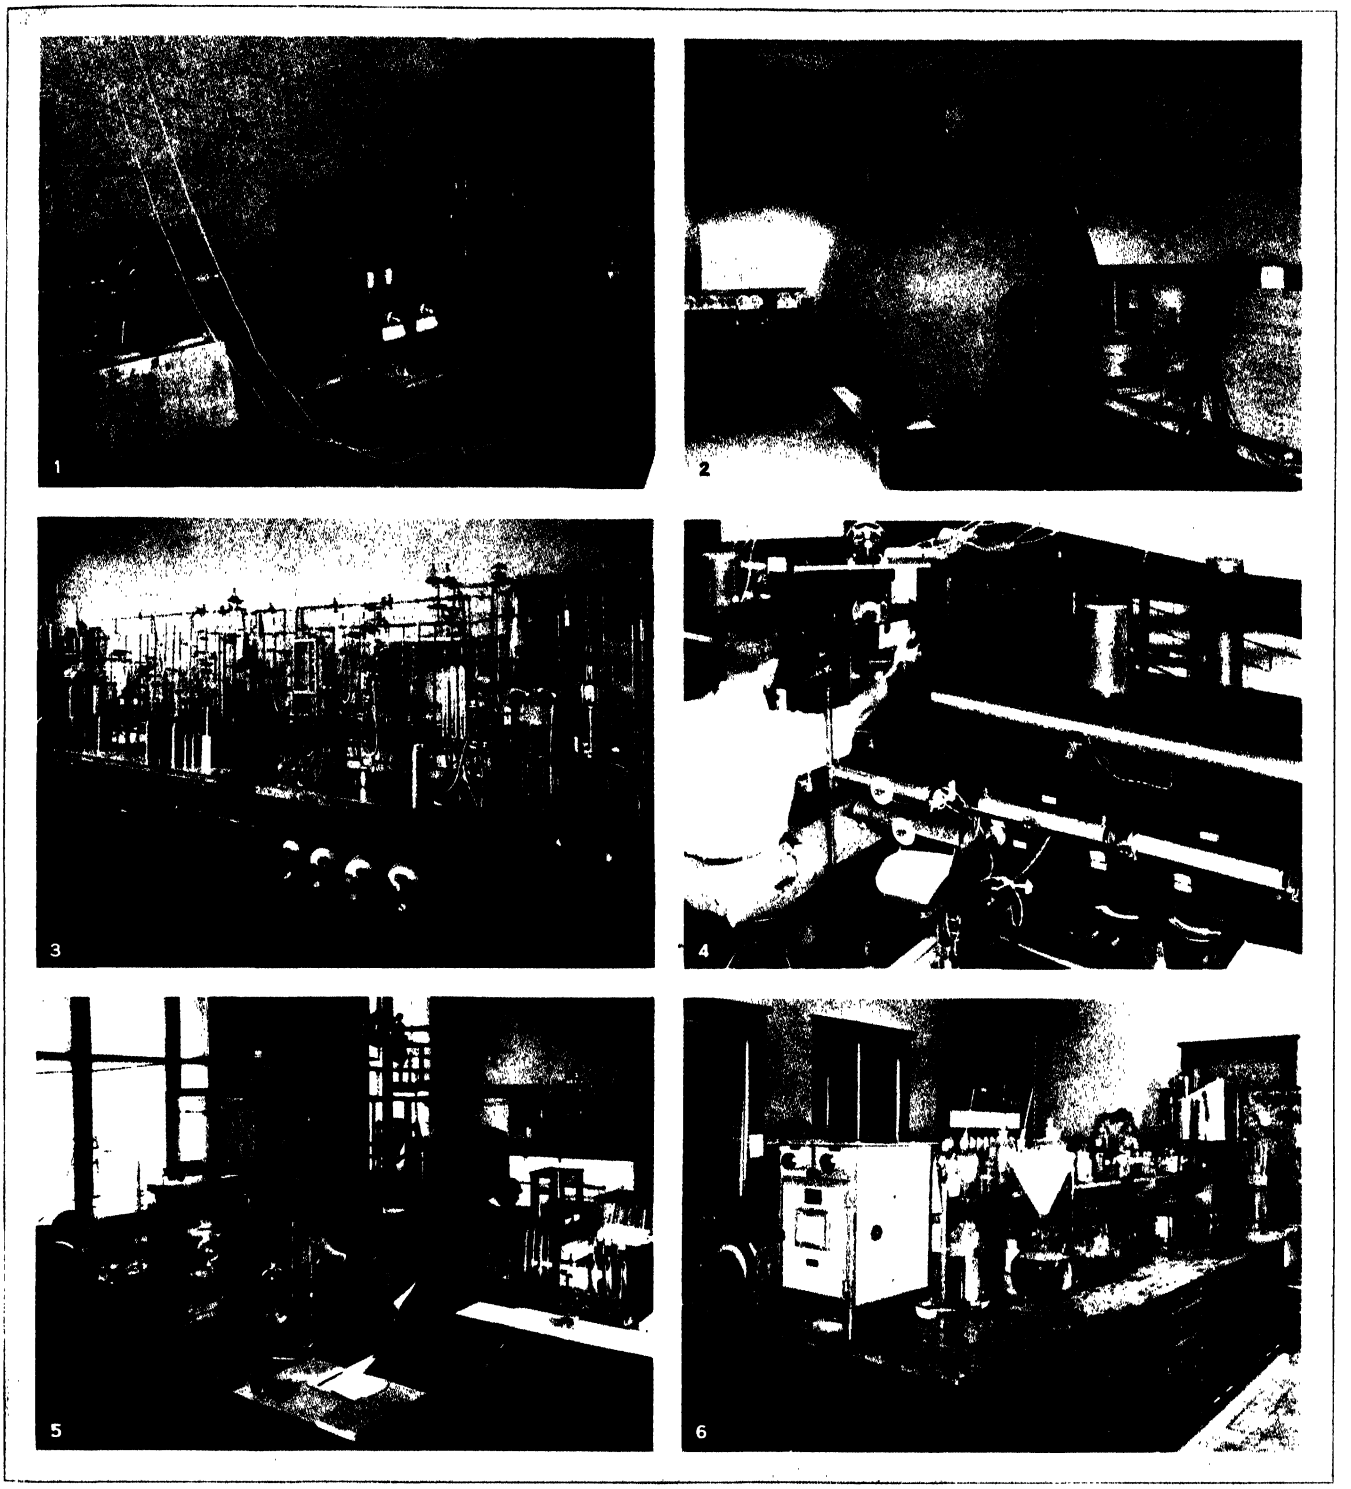
Mendel's Work.—It was the desire for knowledge, pure and simple, that led the Abbé Mendel in his monastery at Brünn to unravel some of the laws of heredity (*q.v.*) by crossing various kinds of peas. When, at an agricultural institute, the laws that he discovered and the methods he employed are utilized to improve the breed of cattle or to produce new and more valuable forms of wheat, the research has become industrial.

The Structure of Matter.—At present physicists in many countries are investigating the properties of matter by X-ray analysis, determining the forms of lattice in which the atoms which constitute the substance are arranged and endeavouring to draw conclusions applicable to all matter; this is a great work of pure research. The metallurgist employed in some works or industrial research laboratory seeks to use the results of the physicist and the methods which have been devised to enable him to learn, for example, why steel is hardened by quenching, what is the cause of the deleterious effect of phosphorus on copper, or why cast metal which is brittle can be made soft and ductile by heat treatment and mechanical work. This is industrial research. Such a worker must carry his investigations further in order that they may be of use to industry. In his laboratory some method devised for making and treating a new and valuable alloy works perfectly or some instrument designed to register the course of a factory process appears foolproof and without a fault; in the factory the alloy cannot be worked or the instrument fails under the first real test; it is his business to find out why; to make the advances of science—advances due in part to his own researches—available for industrial purposes.

Here a distinction should be drawn between the research laboratory of a works and the works laboratory; where both exist there may well be close co-operation, and possibly joint control but the spheres are distinct. In any modern factory a works laboratory of some sort is essential, to check the purity of the materials employed and to ensure that the product is up to standard an engineering works will have its chemical laboratory for this and similar purposes, its testing laboratory where the strength and character of its manufactures are sampled before they are put upon the market; but such work is not research; though it often may indicate where research is necessary, and lead up to original investigations of high value to the firm.

The works manager knows that for success the temperature at some point in a complicated process must be kept within narrow limits, whereas during other operations large variations of temperature have little effect. Samples which fail come to the works laboratory for examination, and inquiry shows that the temperature limits at this critical stage have been exceeded. Such an occurrence naturally leads a competent chemist to inquire what is the nature of the action which takes place at this critical temperature; how does the product produced, when the temperature limits are over-stepped, differ from the proper article? This inquiry may lead to a long and intricate investigation with results of the utmost importance to the firm. It may be found, for example, that a slight change in the composition of the material will render the close limits unnecessary and will reduce greatly the care and attention required for the manufacture. The problem has become one for industrial research, not merely for routine testing, and the consequences of that research have proved to be simplification of manufacture and cheapening of the product.

In Great Britain nearly 50,000,000 people must be supplied with food, mostly brought from beyond the seas, and this food must be paid for with the products of industry at home, by the goods manufactured in great part from materials purchased from abroad but dependent on the coal and iron of English mines and by the knowledge and skill of English manufacturers. It is of the utmost importance that the high quality of those goods should be maintained, the methods of their manufacture improved and the costs of production reduced. In the words of a recent report: "Scientific and industrial research is an essential factor in the national effort on which the continued maintenance of our present population unquestionably depends." And these words, though used here for England, apply to the other nations of the world as well.



And now we come to consider the means taken to promote industrial research and its present position and work in various lands.

These means are various; the state in a number of instances has organized research laboratories devoted mainly to industrial problems; large private firms have established similar laboratories under their own control, while attempts have been made by the formation of research associations to combine the efforts of a number of firms concerned in the same industry. The universities too, and technical colleges have aided the endeavour by organizing more fully the teaching of science and giving facilities for the training of research workers.

Germany.—It needed a catastrophe to produce the results which have been attained. The Reichsanstalt in Berlin was a direct outcome of the war of 1870. Established in two divisions, the one devoted to pure science, the other to its applications, its founders realised the close interdependence of the two, and while the first division dealt to a large extent in questions bearing on the fundamental units and standards of measurement whether in heat, electricity, light or any other branch of physics, the second division was concerned mostly in the application of the principles which resulted from these investigations to the advancement of German industry and manufacture.

At the same time technical colleges were established in a number of centres; of these, perhaps the colleges at Charlottenburg and Darmstadt were the most important, and from their professors and students came a stream of scientific facts and discoveries, many of great value to industry, which were eagerly seized upon and assimilated by men at the head of great industrial concerns who had realised that science was the foundation of their success.

In their own factories these men were no less active and far

SCENES IN SOME OF THE RESEARCH LABORATORIES OF THE UNITED STATES

1. One of the huge wind tunnels used for aeronautical research at Massachusetts Institute of Technology. The tunnel is 80 ft. long and 7 ft. in diameter at centre sections. Model planes are tested under artificial wind velocities up to 90 m. per hour. 2. Scale model of an airplane underground airport test in one of the big wind tunnels at Massachusetts Institute of Technology. The various wire cables leading up from the models are connected with instruments which register the pressure on various parts of the plane. A 14-ft. propeller at end of tunnel generates the gales in which models are tested. 3. World's largest testing machine, at the Bureau of Standards, Washington, D.C.; capable of exerting a force of 10,000,000 lb. in compression. 4. Liquid air experiments at the General Electric Research Laboratory. The white cloud is due to the condensation and freezing of water vapor and carbon dioxide of the air at the extremely low temperature of the liquid. 5. Experimenting with mercury arc rectifiers, the function of which is to connect alternating current to direct current. 6. An X-ray research laboratory in the Department of Physics at the Massachusetts Institute of Technology. 7. Apparatus used to measure the gravitation constant at the Bureau of Standards. 8. An individual physics research laboratory in the Department of Physics at the Massachusetts Institute of Technology

seeing. Charlottenburg and the Materials Prüfungs Amt at Gross Lichterfelde which developed from it taught the engineer and the metallurgist the value of research. Its professors devised delicate instruments for use in investigating the properties of materials; the Martens Extensometer is an example. Sorby, of Sheffield, in 1864 was the first to investigate the structure of metals and alloys by the aid of the microscope, but his work was not pursued until, at a later date, Osmond in France and Martens in Germany took up the study independently and showed its importance to the industrialist.

In electrical science, also, the work of the Reichsanstalt had a marked effect and the great electrical firms—the Allgemeine Elektricitäts Gesellschaft, Siemens and Halske and others—established research laboratories to develop for their own purposes and private benefit the results of scientific investigations.

Nor should the great chemical firms be forgotten. Perkin, in England, was the founder of the modern dye industry, but it was in Germany that this teaching first bore practical results. The Badische Anilin Fabric and other similar works were founded and huge sums were spent in developing new methods and inventing new dyes. Artificial indigo took the place of the natural product, with the inevitable result to the Indian industry. Germany had learned the lesson, and industrial research promised, unless other countries woke up, to give her the leading position among the manufacturing nations of the world.

Great Britain.—In England, until towards the end of the 19th century, the danger was hardly appreciated. At meetings of the British Association and elsewhere Sir O. Lodge and others had pointed out the value of the Reichsanstalt to Germany, the need that England should have a similar institution. In 1900 the National Physical Laboratory began in a small way—the expenditure during the first year was £5,479—in the old buildings of the Kew Observatory at Richmond. In 1901 the work was transferred to Bushy House, Teddington, with a staff of eight scientific assistants and six attendants in addition to the director. The scientific character of its work was secured by placing the ultimate control in the hands of the Royal Society, while a close connection with industry was maintained by having representatives of the great engineering societies on its governing body. The laboratory, at the time the only public institution in the country devoted to the application of science to industry—to industrial research—grew slowly and prospered for the next 12 or 14 years, and when the World War came, it was in a position to be of material service to the country.

About the same time, the British Engineering Standards Committee was founded, chiefly at the instance of Sir John Wolfe Barry, who had realised the loss caused by the infinite number of standards used by engineers and the advantages to be gained by a system based on accurate measurement and a careful investigation of the properties of the materials employed in constructures. In this work the National Physical Laboratory co-operated very fully. Meanwhile at an earlier date industrial research of importance had gone on in a few laboratories attached to firms in Sheffield and elsewhere. The work of Sorby on the micrographic structure of metals has already been referred to and at a later date Roberts Austen of the Mint utilized this method of inquiry in his investigation of a broken rail which had led to a serious accident on the Great Northern Railway. Manganese steel was produced from the laboratory of Sir Robert Hadfield in 1882 as an outcome of a scientific inquiry into the properties of alloys; many results of high value have since come from the same source.

France.—In France, work of value was being done in various places; the Laboratoire d'Essais and the Laboratoire Central d'Électricité both contributed. The metallurgical work of Osmond and Le Chatellier was of marked importance, while the discovery of the special properties of Invar—an alloy of nickel steel—by Gulleaume has proved of value in many industries.

International Standards.—One of the marked consequences of industrial research has been the realisation of the importance of international standards of measurement, and as a result international co-operation between the standardizing laboratories in various countries and other bodies concerned with standards has become necessary. From this need arose the Bureau International des Poids et Mesures at Sèvres and various international associations such as the International Electrotechnical Association or the Association for Testing Material. In 1908 the British Government summoned an International Congress in London at which the system of electrical units, now universal throughout the world, was adopted.

War Problems.—This is not the place to give any account of the influence of science on war; experience showed it to be vital and the phrase that Science won the War, interpreted to mean that without science the War would have been lost, only expresses the truth. In the Allied countries on both sides of the Atlantic, men and women were at work solving problems of vital importance. Facilities for research were open to them, funds undreamed of in peace time were at their disposal, and the results of their endeavours contributed to a more general acceptance of the view that in peace time industry would benefit in the same way from scientific inquiries wisely guided and pursued.

Department of Scientific and Industrial Research.—And so, in Great Britain as elsewhere, a movement was started to organize in some more definite way the connection between science and industry. The establishment of the Department of Scientific and Industrial Research was the outcome of this movement. This was announced by Lord Crewe, Lord President of the Council, at the end of 1916 in reply to a deputation from the Joint Board of Scientific Societies headed by Sir Joseph J. Thomson, P.R.S. An advisory council of scientific men was established and the sum of £1,000,000 was placed at the disposal of the department to be used in the application of science to industry.

The financial responsibility for the National Physical Laboratory, with a staff which before the end of the War had grown to 600, was transferred to the department; boards were set up for fuel research, food investigation, building research and various other subjects, while a number of co-ordinating bodies were established to deal with researches of importance to Government departments, especially those bearing on industry. These researches are carried on either in special laboratories or at one or other of the national laboratories; the Geological Survey and Museum became one of the activities of the new department, which thus undertook the task of guiding and supervising the various official agencies for making the advances of science of service to national progress. The department also aids the work of the Aeronautical Research Committee which—at first as the advisory committee for aeronautics—has contributed in no small degree to the science of aviation.

Co-operative Research.—But the department has done more than this. In Germany and America many of the great industrial firms have their own research laboratories; reference has already been made to some of the results on German industry. But research laboratories are costly; in many industries in England the firms concerned are small, a private research laboratory is too expensive to be contemplated, besides a number would produce wasteful overlapping. Hence the attempt was made to introduce a system of co-operative research. In an effort to lead manufacturers to rely more on scientific results, research associations have been set up. Each of these consists of a body of men engaged in the same industry who associate themselves for the purposes of research bearing on their industry. Each association has its own director of research, or similar official, under whose guidance the work planned by its council is carried on either in their private laboratory or by arrangement at the National Physical Laboratory or in the laboratories of some university or technical college.

The work is financed in part by the associated firms, in part from the million fund, usually on a pound to pound basis guaranteed under certain conditions for five years and with a limit of £5,000 a year to its amount. In 1927 there were 24 such associations in existence; the balance in the million fund is now £352,292; a substantial part of this is required to complete the payments already promised. In a number of cases the first five years for which the grant was made have elapsed and the department, with a view to determining its future course, has arranged for a report from some independent body on the work and progress in each

case. In a recent report to the committee of the Privy Council responsible for the work of the department, the advisory council writes of the associations:

"We have no doubt that they have already produced results of financial value far greater than their whole expenditure and have been instrumental in introducing scientific methods and encouraging scientific spirit in industry."

It is clear from the general tenor of these reports that 5 years is insufficiently long even under the most favourable conditions to set a research association on its feet and make it independent of government assistance. To devise a programme, collect an efficient staff and obtain results all take time. Besides, there is much educational work to be done; half-hearted supporters need to be converted by results before they will contribute freely; trade rivalries tend to prevent complete co-operation; trade has been bad and returns barely sufficient to keep old ventures going; there has been little to spare towards an expenditure of whose value the manufacturer is only half convinced. And so the department has now under consideration the steps that can be taken to maintain the work for some years to come and, in the case of some important associations, has already settled the terms of future grants (*see* report of the Department for 1925–6).

Training of Workers.—But there are other ways in which official support is being given to industrial research, and among these the schemes for training research workers is most important. Under this scheme young graduates are assisted to carry out researches under the guidance of some competent professor, while, in a number of cases, funds have been granted to prominent workers to enable them to pursue inquiries of importance.

The royal commission for the exhibition of 1851 administers for the advancement of education and research funds arising from the balance left when the exhibition closed. For many years past its scholarships and studentships have been of great value. The commission has inaugurated a number of Industrial bursaries given on the recommendations of the universities and technical schools to men trained in science who were prepared to enter, as apprentices or students, engineering or other works. In this way, a stream of trained workers in science is provided for industry.

Private Research Laboratories.—Before concluding, reference should be made again to the research laboratories of prominent firms; in England, the laboratory of the General Electric Co. at Wembley occupies a leading place; but it is to Germany and America that we turn for striking examples of what a works research laboratory can do (*see* below). (R. T. GL.)

THE UNITED STATES

The history of American technology reveals plainly that within the past four or five decades, and mostly within the last 25 years, manufacturing practice has progressed vastly more than in any previous era. In all the important branches of industry empiricism has been supplanted by industrial research. It was estimated in 1927 that there were at least 16,000 scientists and engineers engaged in research on behalf of the industries of the United States. Assuming this figure to be approximately correct, as it undoubtedly is, over $100,000,000, probably $110,000,000, is being expended annually in supporting industrial research. About half of this amount is spent on chemical laboratory investigations, most of which are conducted by companies in their own plant laboratories.

Industrial Research by Companies.—The largest research establishment in the United States is the Bell Telephone Laboratories, Inc., in New York City, which employs about 2,000 physicists, chemists and engineers for original investigation and development of new forms and improvement of existing forms of apparatus and equipment for electrical communication. Next in collective size are the five laboratories and the main-office chemical organizations of E. I. du Pont de Nemours and Co., Wilmington, Del., wherein over 850 chemists and engineers are studying problems of the heavy chemical, paint, lacquer, solvent, dye, rubber and explosive industries. Other great laboratories are operated by the International Harvester Company of America, Chicago, Ill.; the General Electric Co., Schenectady, N.Y., Lynn and Pittsfield, Mass., and Cleveland, O.; the Goodyear Tire and Rubber Co., Akron, O.; the General Motors Corporation, Detroit, Mich.; Thomas A. Edison, Orange, N.J.; the B. F. Goodrich Co., Akron, O.; the Westinghouse Lamp Co., Bloomfield, N.J.; the New York Edison Co., New York city; the United States Rubber Co., New York city and Detroit, Mich.; the Eastman Kodak Co., Rochester, N.Y.; and the National Carbon Co., Inc., Cleveland, O.

In the last 20 years numerous companies have taken advantage of the *industrial fellowship system* of Mellon Institute of Industrial Research (*q.v.*) as a means of solving problems in manufacturing practice. In 1928, 53 fellowships were being sustained by as many different companies, largely chemical manufacturers, while 12 more fellowships were being supported by trade associations.

About 70 individual companies in the field of chemical industry are making research grants to educational institutions. Chief among them in 1928 are E. I. du Pont de Nemours and Co., supporting 20 fellowships, and the Grasselli Chemical Co., which sustains five university researches. The American Petroleum Institute is administering a research contribution of $100,000 annually for five years from John D. Rockefeller and the Universal Oil Products Co. The fund is distributed among selected institutions to support investigations of basic problems in petroleum technology.

There are at least 190 college laboratories that are used not only for purposes of instruction, but also to a considerable extent for industrial research work and for commercial testing.

A considerable number of companies, mostly small concerns that have no laboratories of their own, or larger companies that encounter few problems or are engaging in research for the first time, are regular or occasional clients of consulting laboratories. There are about 300 of these commercial laboratories in the country, and some of them are strongly staffed and excellently equipped for scientific investigation, particularly in specific industries. For example, a Western firm of consultants, which has a main laboratory and also three branches in other cities, employs 180 scientists and their assistants for varied research. Another firm operates nine laboratories. Most of these commercial organizations do testing as well as research work.

Trade Association Research.—The U.S. Department of Commerce has expressed the opinion that "among constructive activities of trade associations none is more fitting nor more profitable than scientific research." The study of production and distribution problems to evolve more efficient and more economical methods has in fact become a leading association activity. We shall describe here associative industrial or technological research, and not commercial or economic investigations, which, while entirely different in nature, are often related to the former.

Five different procedures are being applied with success in conducting associative industrial research. (1) A number of associations are co-operating with Government departments and bureaus in accordance with the *research associate plan.* (2) Other associations are sustaining scientific investigations in Mellon Institute of Industrial Research at Pittsburgh, according to the *industrial fellowship system* of this institution. (3) Some associations are supporting fellowships or scholarships in educational institutions. (4) Still other associations are carrying on research in commercial establishments, such as the laboratories of professional consultants. (5) A few associations have founded their own laboratories.

The Research Associate Plan.—For about 35 years the scientific and technical research facilities of various Governmental departments have been available, by legislative enactment, to duly qualified workers (Supp. Rev. Stat., 2, 71–2, 1532; Stat. L., *27*, 1010; Bureau of Standards Circular No. 296). This plan has been developed especially in the National Bureau of Standards, where there were in 1928 over 100 research associates employed by 63 associations or specific groups. Each associate is subject to the bureau's regulations and has most of the rights and privileges of the members of the bureau staff. The investigational results are immediately accessible to the industry concerned and are published by the bureau. The bureau's staff of specialists may be consulted by the association and its research worker, and the latter

is also permitted to use the scientific equipment, special laboratories and shops of the institution.

In general, this flexible, closely co-operative plan has been successfully applied. There are in fact several notable instances of economic savings to technology from research in the bureau. It is reported (Department of Commerce, Domestic Commerce Series No. 20, "Trade Association Activities," 1927) that $15,000,000 is being annually saved to industry and the public from the bureau's brake-lining research, that the annual savings from its tire investigations amount to $40,000,000, and that the motor-fuel studies are saving $100,000,000 each year. Research in the bureau also eventuated in the founding of a dextrose industry in the United States. The following are among the outstanding investigations in progress in 1928: portland cement, paper, headlighting, welded rail joints, metal roofing, textiles, elevator safety equipment, gas appliances, gypsum, tile, steam, terra cotta, and fuels.

The Bureau of Chemistry and Soils and the Forest Products Laboratory of the Department of Agriculture and the Bureau of Mines of the Department of Commerce have also advanced technology by researches on behalf of various industries. The Bureau of Mines is conducting various investigations in mining, metallurgy, health and safety, and on the economics of the production, preparation and utilization of minerals. The research laboratory of the American Society of Heating and Ventilating Engineers is located in the Pittsburgh station of this bureau. The American Gas Association and also 28 companies representing the electrical, mining and metallurgical industries are supporting jointly ten research studies in mining and metallurgy at Carnegie Institute of Technology in co-operation with the Bureau of Mines. Certain researches of the Public Health Service of the Department of the Treasury—particularly the investigations of dusty trades, illumination of buildings, and motor fuels—have likewise benefited industry.

The Industrial Fellowship System.—About 23% of the research of Mellon Institute (in 1928) is sustained by associations of manufacturers, according to the institution's industrial fellowship system (*see* MELLON INSTITUTE OF INDUSTRIAL RESEARCH). These association fellowships pertain to hat technology, sewer pipe, garment renovation, insecticides, refractories, laundering, pine products, alcohol denaturation, fur, iodine and stearic acid. The Laundryowners' National Association, constituted of 2,000 members, has been supporting extensive investigation in the institute since 1915. Its fellows have contributed much to the knowledge of the properties of textiles and of the uses and effects of laundry supplies; they have eliminated defects in laundering practise, have worked out washroom procedures that are now standard, and have drawn purchase specifications for soaps, sodas, bleaches, starches and blues. The American Refractories Institute's multiple industrial fellowship has been in continuous operation since 1917. Its incumbents have enriched both refractories technology and metallurgy by their broad studies of the evaluation of refractories for specific purposes and by the improvements that they have made in manufacturing and testing methods.

An association fellowship of this type enables direct research service to a number of industrial concerns instead of to an individual company. Its activities also give rise to stable relations of co-operation among the members of the association by the exchange of technical experience and research results. An association fellowship usually acts as a clearing-house of information for the sustaining organization, and gives technical assistance and scientific advice to the company-members. One of the prominent advantages of association research is that it enables a small manufacturer, who cannot afford to have a research laboratory of his own, to profit from the investigational work in the same way as a larger manufacturer. Association research reduces the cost factor to a minimum and thus promotes the welfare of manufacturers in the field concerned, without respect to size. Moreover, problems may be studied that require more time and expense than should be borne by a single manufacturer or company, in view of the wider application of the results. The correlation of research effort, such as is done in the fellowships supported by associations, prevents unnecessary duplication in scientific inquiries.

Association Fellowships in Educational Institutions.—This class of research has become important in many industrial fields. It serves to train technical specialists as well as to aid in solving production problems. Columbia university, Iowa State college, and the universities of Illinois, Michigan, Wisconsin, Minnesota, Chicago, Cincinnati and Pittsburgh are in the fore of the institutions that are encouraging industrial research by associations and also by individual companies.

Association Owned Laboratories.—Industrial research is not conducted in any set type of laboratory or in accordance with any fixed plan. The nature of the problems, the financial support available and the uses to which the research findings are to be put mainly determine the method. If the problems are extensive and the association members are so appreciative of the value of research that they will contribute to the building and maintenance of a laboratory, it is often advisable for an association to do its own research.

Co-operating Agencies.—The National Research Council serves as a general clearing-house of information regarding research work undertaken throughout the country. Its division of engineering and industrial research endeavours to co-ordinate the scientific resources of the nation as regards engineering and secures the co-operation of engineering agencies in which investigational facilities are available. It works in co-operation with the Engineering Foundation (*q.v.*) and the various national engineering and technical societies. Associations or companies undertaking research may ascertain from the council what work has already been done or is in progress along similar lines, thus avoiding duplication of effort.

The American Engineering Standards Committee, the American Society for Testing Materials and the American Engineering Council are some of the organizations whose effectiveness depends in many cases on the collaboration that they receive from trade associations as well as individual concerns that carry on research.

(W. A. HA.)

RESEDACEAE, in botany, the mignonette family, dicotyledonous plants, mostly xerophytic herbs. There are six genera and about 60 species. *Reseda odorata* is the mignonette (*q.v.*); *R. lutea* is dyer's woad. (*See* WOAD.)

RESENDE, ANDRÉ DE (1498–1573), the father of archaeology in Portugal, began life as a Dominican friar, but about 1540 passed over to the ranks of the secular clergy. He travelled in Spain, France and Belgium, where he corresponded with Erasmus and other learned men. He was also intimate with King John III. and his sons, and acted as tutor to the Infante D. Duarte. In Portuguese he wrote: (1) *Historia da antiguidade da cidade de Evora* (1553); (2) *Vida do Infante D. Duarte* (1789). His chief Latin work is the *De Antiquitatibus Lusitaniae* (Evora, 1593).

See the Life in Farinha's *Collecção das antiguidades de Evora* (1785).

RESENDE, GARCIA DE (1470–1536), Portuguese poet and editor, was born at Evora, and began to serve John II. as a page at the age of ten, becoming his private secretary in 1491. He was present at his death at Alvor on Oct. 25, 1495. He continued to enjoy the same favour with King Manoel, whom he accompanied to Castile in 1498, and from whom he obtained a knighthood of the Order of Christ. In 1514 Resende went to Rome with Tristão da Cunha, as secretary and treasurer of the famous embassy sent by the king to offer the tribute of the East at the feet of Pope Leo X. In 1516 he was given the rank of a nobleman of the royal household, and became *escrivão de fazenda* to Prince John, afterwards King John III., from whom he received further pensions in 1525. Resende built a chapel in the monastery of Espinheiro near Evora, the pantheon of the Alemtejo nobility, where he was buried.

Resende collected the best court verse of the time in the *Cancioneiro Geral,* probably begun in 1483 though not printed until 1516.

The *Cancioneiro* is redeemed from complete insipidity by Resende himself, and his fine verses on the death of D. Ignez de Castro inspired the great episode in the *Lusiads* of Camoens (*q.v.*). Resende is the compiler of a gossiping chronicle of his

patron John II., which, though plagiarized from the chronicle by Ruy de Pina (*q.v.*), has a value of its own. Resende's *Miscellanea*, a rhymed commentary on the most notable events of his time, which is annexed to his *Chronicle*, is a document full of historical interest, and as a poem not without merit.

His *Cancioneiro* appeared in 1516, and was reprinted by Kausler at Stuttgart (3 vols., 1846–52). A new edition was published by the Hispanic Society of America in 1904. The editions of his *Chronicle* are those of 1545, 1554, 1596, 1607, 1622, 1752 and 1798. For a critical study of his work, *see* Antonio de Castilho, *Excerptos, seguidos de uma noticia sobre sua vida e obras, um juizo critico, apreciação de bellezas e defeitos e estudo da lingua* (Paris, 1865). Also Anselmo Braamcamp, *As sepulturas do Espinheiro* (1901) *passim*, especially pp. 67–80, where the salient dates in Resende's life are set out from documents recently discovered; and Dr. Sousa Viterbo, *Diccionario dos Architectos . . . Portuguezes*, ii. 361–74.

RESERVE: *see* ARMY and the sections "Defence" of FRANCE, GERMANY, UNITED STATES and other countries.

RESERVES: *see* BANKING AND CREDIT.

RESERVES, NATURAL: *see* PHYSICAL RESOURCES.

RESERVOIRS. These may be divided into two classes, "impounding reservoirs" and "service reservoirs," the latter being concerned with the distribution of water (*see* WATER SUPPLY).

Impounding Reservoirs.—Owing to the fact that the flow of streams and rivers varies greatly throughout the year, it is necessary to provide works to store water if any substantial use is to be made of the annual discharge. Such works are known as impounding reservoirs, their function being to store water when the stream flow is ample for the purpose of augmenting the natural flow in dry weather.

The urgency for the construction of such reservoirs must have become apparent in very early times in countries where the climatic conditions were such that the streams ran dry for a portion of the year, and records exist of one being made in Ceylon as early as 504 B.C. Anciently reservoirs were formed by an embankment across the valley through which a stream flowed, and were sometimes of vast extent, the Padavil-Colan Tank in Ceylon, for instance, having an embankment 11 m. long and, in parts, 70 ft. high.

Storage.—Having selected a catchment area capable of yielding sufficient water, the capacity of the reservoir has next to be determined. This will depend upon the incidence and intensity of the rainfall and the loss by evaporation and absorption, conditions which vary within wide limits. In countries subject to long periods of drought, the necessary capacity will be greater than in those enjoying a temperate climate, and in India, for instance, where the rain falls only during monsoon periods, two years' storage of the daily quantity may be necessary.

Few records exist of the flow of streams in the British Isles taken over a sufficiently lengthy period to be of service, and recourse has generally to be made to the annual rainfall records, from which the annual discharge of the stream is deduced. Long period rainfall gaugings show that the rainfall of the driest year is about two-thirds, the mean fall of the two driest years about three-quarters, and the rainfall of the three driest consecutive years about four-fifths, of the average annual rainfall. Notwithstanding the wide variation of climatic conditions, these proportions hold fairly well over a large portion of the land surface of the globe (*see* "The Variations of Rainfall," by A. R. Binnie, *Proc. Inst. C.E.*, vol. 109).

As storage increases in relation to the average flow of a stream, the maintainable yield increases in a decreasing ratio until a maximum is reached where there would be little advantage in further increase, and in the British Isles the economic limit is generally taken as that capacity which would be sufficient to equalize the flow of the three driest consecutive years.

The average annual rainfall of the three driest consecutive years, being approximately four-fifths of the average annual rainfall; and the average annual loss by evaporation and absorption being about 14 inches; the average annual discharge of the stream during the three driest consecutive years would be that due to $\frac{4}{5}$ average rainfall—14 inches running off the catchment area, which may be denoted by f. The formula known, from its author, as the Hawksley Formula gives the number of days storage which should be provided to maintain this flow $=\frac{1000}{\sqrt{f}}$.

In many cases it is not necessary to provide so large a storage, as some quantity may be required which is less than the average flow of the stream during the three driest consecutive years.

Fig. 1 gives the relation between the maintainable yield and the capacity to be provided for catchment areas in the British

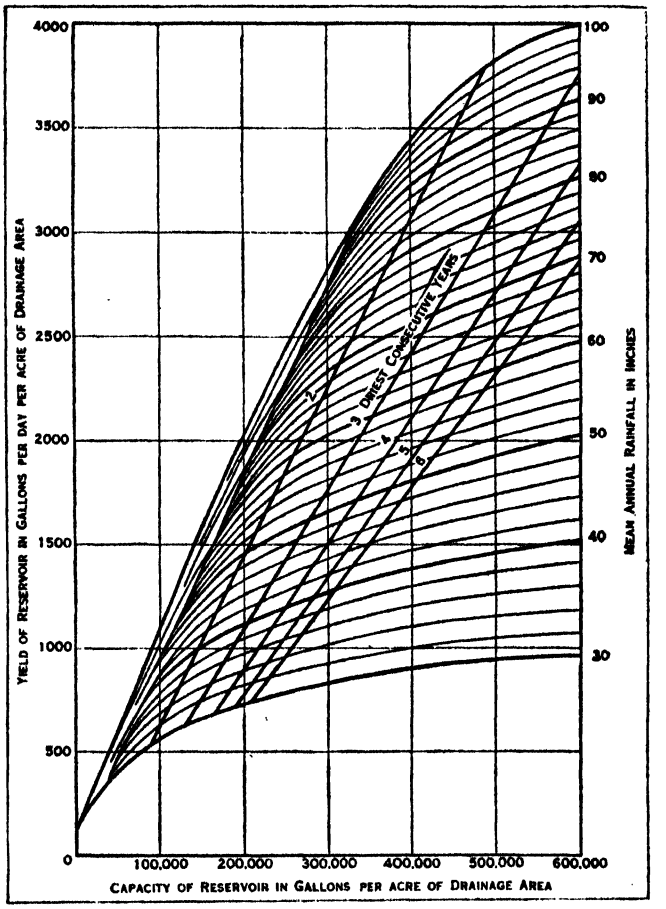

FIG. 1

Isles having a mean annual rainfall varying from 100 to 30 in., and is due to the investigations of Dr. G. F. Deacon. The capacity of the reservoir in gal. per ac. of catchment area is shown on the base line, and the yield of the reservoir in gal. per ac. per diem is given by the length of the vertical line between that capacity and the curve of average rainfall, the yield in gal. per ac. per diem being read from the vertical scale at the left-hand side. The storage required for any particular average rainfall to balance the average stream discharge during different series of consecutive dry years, is given by the diagonal lines which intersect the curve of rainfall on the diagram.

The diagram gives the capacity above the lowest draw-off level of the reservoir, and as it is undesirable to abstract muddy water for supply, this level should be well above the bottom of the reservoir. The loss by evaporation from a water surface is greater than the loss on the catchment area, and in the British Isles the depth of the reservoir should be about 6 in. more than would be required to give the gross storage, whereas in tropical countries the allowance may be as much as 6 ft.

TYPES OF DAMS

Dams may be divided into two classes, masonry or embankments; and the selection of the particular type will depend upon the nature of the materials on which they will rest, and which are available for construction.

Where good sound rock exists at no great depth from the surface, a masonry dam is to be preferred, but where the rock can

only be reached at a considerable depth, the cost is prohibitive.

Masonry Dams.—Masonry dams should be arched in plan concave to the water face where the length of the dam is not too great, as such a form adds to the stability, and the pressure of the water tends to close temperature or contraction cracks at right angles to the axis of the dam. It is desirable to slope the foundations towards the water face, especially where the depth below the surface is moderate, as this reduces the tendency to slide on the foundations and the possibility of overturning due to the uplifting pressure of water penetrating between the masonry and the rock. The design should avoid the development of tension in the masonry, tending to rupture the dam on a horizontal plane; and the maximum pressure at any point in the masonry should be limited to 10–15 tons per sq.ft., depending on the materials used for construction and the nature of the underlying rock. Prof. Rankine pointed out the importance of avoiding tension, and evolved the theory on which most modern dams have been designed, viz.: that the resultant pressure due to the weight of the masonry and the water thrust must fall within the inner third of the dam if tension is to be avoided. Any fissure developing at the water face due to tension tends to increase owing to the water pressure, and may ultimately lead to the failure of the dam (*see* Prof. Unwin, *Proc. Inst. C.E.*, vol. 126, and E. P. Hill, vol. 129).

The masonry of a dam is not isotropic as horizontal planes of weakness, where new work is superimposed upon that which has set, are difficult to avoid. It is advisable therefore to step the masonry at the water face so as to avoid the construction of a horizontal joint between old and new work.

The arched form of dam is economical when the radius of curvature is comparatively small, as the sectional area can be decreased by designing the dam as a horizontal arch transmitting the water thrust to its abutments. For reasons of economy modifications of the simple type of masonry dam have been introduced; these dams are of ferro-concrete construction, the pressure of the water being transmitted to buttresses by means of steel reinforced slabs or arches.

Earth Embankments.—The profile of the embankment requires careful study of the materials of which it will be composed, and slips have frequently occurred, leading to the complete or partial failure of banks, due to lack of local study and the adoption of a design which was unstable. Light sandy soils will stand at a high angle of repose, but clays or plastic materials require flatter slopes, the inclination decreasing as the base of the embankment is approached. On fig. 2 the inner line profile would apply to good banking material, and the outer line to clay or plastic material.

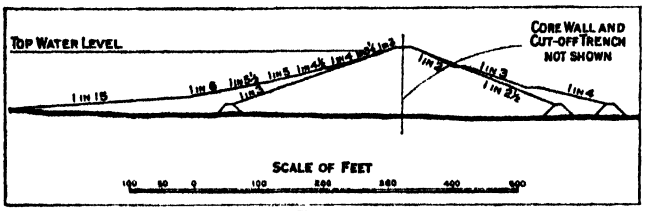

FIG. 2

Care must be exercised to prevent the saturation of the outer slope of the bank, and when possible it should be composed of freely draining material. When such materials are not available, the outer portion should rest on a layer of stone terminating in a stone toe, vertical drains of dry stone being carried up through the bank at intervals.

Cut-off Trench.—In order to prevent percolation below the bottom of the embankment, a trench is first excavated across the valley bottom, carried down—if possible—to an impermeable substratum and continued into the hillsides, so as to cut off any percolation below top water level. This is filled with impermeable material, preferably concrete, so as to form a barrier to percolation below the bank; and an impermeable core wall is brought up in continuity with this barrier to prevent percolation through the bank.

Core Walls.—Puddle is the material generally used in the British Isles to form the core wall, and reinforced concrete in America. Puddle is not an absolutely impermeable material, and the thickness of a puddle core wall must be much greater than that of a concrete core wall. The use of concrete core walls has been limited in the British Isles owing to the apprehension that such walls would crack under pressure due to unequal settlement of the embankment. That such fears are unfounded is proved by the numerous successful examples of such construction in America.

The very greatest care must be exercised in the construction of a puddle core wall to prevent the occurrence of any layer through which water could pass owing to the erosion which may take place, causing the formation of a cavity and the failure of the bank; whereas no erosion of the concrete would take place, and a crack would soon be sealed by earth carried in suspension by the water.

Tunnel Outlets.—It is necessary to divert the stream during construction, and for this purpose it is advisable to construct a tunnel round one end of the bank through which the stream may flow, and through which the supply pipe can ultimately be laid from the Valve Tower. A cheaper form of construction is to build a culvert under the bank, but many cases of whole or partial failure of such culverts have occurred due to the varying earth pressure. (*See* C. J. Wood, "Tunnel Outlets," *Proc. Inst. C.E.*, vol. 59.)

Flood Works.—When a reservoir formed by a masonry dam overflows, water passes harmlessly over the top of the masonry into the stream below. It is obvious, however, that water cannot be allowed to overflow an earth embankment, as the material would rapidly erode, leading to the failure of the bank. It is therefore necessary to allow for the escape of flood water in such a way that the water level can never rise to a height that would endanger the bank.

The usual flood escape is provided by a weir of such a length and placed at such a level below the top of the bank as will ensure that the water in the reservoir can never rise above it, the weir discharging into a masonry channel placed in the hillside at one end of the bank. Another and more economical escape consists of a vertical shaft communicating below with the tunnel through which the stream was diverted during construction and terminating above in a bell-mouthed opening, the periphery of which forms the overflow weir.

Flood Intensity.—The maximum intensity of the flood discharge over the weir will depend on the extent of the catchment area, the maximum intensity of rainfall during a period bearing relationship to that area, and many other factors, such as the inclination of the valley, the steepness of the slopes, the permeability of the surface, and the presence of lakes or obstructions which would delay the discharge. It is impossible to determine the exact effect of many of these factors, and therefore recourse must be made to actual records of the maximum discharge from catchments of different areas.

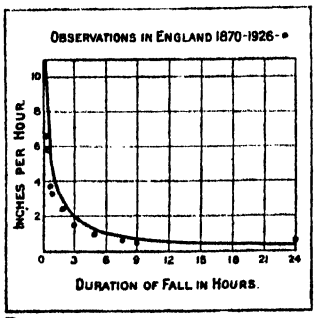

FIG. 3.—MAXIMUM RAINFALLS OF RARE INTENSITY

The main factor in determining the maximum intensity of a flood must obviously be the amount of rain which fell in a given period, a condition which varies so widely in different parts of the globe, that records of flood discharge in one country would not be applicable to another.

The curve on fig. 3 shows the relationship between rainfall and period, and is derived from the formula determined by Prof. Talbot as applicable to the Eastern United States for maximum rainfalls during different periods. The small circles show actual observations made in the British Isles, from which it appears that Talbot's curve fits British conditions fairly well. This fact is of importance as indicating that records of floods in the Eastern

States are of assistance in arriving at the maximum intensity of discharge from different catchment areas in the British Isles. The larger the catchment, the smaller is the flood discharge per unit of area.

Unfortunately, the estimates of maximum flood discharges from small catchment areas, are scanty and not very reliable. Most reservoirs are placed at comparatively high altitudes, where the catchment area is small, in order to impound water free from pollution and to furnish water to the district of supply by gravity. Failures of such reservoirs, due to insufficient provision for the discharge of flood water, are not infrequent, and demand serious consideration owing to the consequent loss of life and property.

The formula $Q=750/\sqrt[3]{M}$, where Q denotes the maximum flood intensity in cu.ft. per sec. per sq.m. and M the drainage area in sq.m., agrees fairly well with the records of maximum flood intensity in Great Britain. (*See* also WATER SUPPLY; DAM; CATCHMENT AREA.) (W. J. E. B.)

RESHT, the capital of the province of Gilan in Persia, in 37° 17′ N., and 49° 36′ E., on the left bank of the Siah Rud which is a branch of the Safid Rud and flows into the *murdab* or lagoon of Pahlavi (Enzeli). The population in 1928 exceeded 70,000, chiefly Gilakis, with a few merchants and officials, known locally as Iraqis. During the Bolshevik invasion in 1920 about 8,000 refugees left the town, but have since returned; and a large part of the bazaar was burnt. The town is situated in low malarious ground and was originally buried in jungle, but the Russians during their occupation of the place in 1723–24, cleared most of the jungle and it is now surrounded by rice fields. The summer climate is damp, sultry and unhealthy, with an average minimum temperature of 84·5° in August and a rainfall of 32 to 59 inches. The houses are red-tiled or thatched, and raised from the ground, with broad verandahs and overhanging eaves. Most of the streets are paved with cobble stones, an improvement which was begun in 1910; and Resht is almost unique in Persia in having the nucleus of a sewerage system running from the bazaar to the river. There are many caravanserais.

Resht is the centre of important roads in Gilan. The metalled road from Tehran (226 m. distant) via Kazvin to Pahlavi skirts the town on the east, upon which a regular motor transport service is in operation. There is a similar road to Pir i Bazar (4 m. up the river of the same name which runs into the lagoon), whence there is a regular daily service of flat-bottomed sailing boats to Pahlavi. Launches also run between the bar at the mouth of the Pir i Bazar river and Pahlavi. A narrow gauge railway runs alongside the Resht-Pir i Bazar road. A carriageable road also runs laterally from Kasma through Resht to Lahijan, Langarud and Rud-i-Sar on the Caspian sea, following in great part a raised causeway through rice fields, with innumerable wooden bridges over irrigation canals. Resht is a centre of the rice trade and of the activities of the silk industry of Gilan, but the principal centre of the latter is Lahijan. There is a town telephone service with trunk lines to Pahlavi, to Rud-i-Sar, to Pir i Bazar and to Kasma. The Imperial bank of Persia has a branch at Resht and the town is lit by electric light.

Resht suffered a good deal during the World War, first from the Russian army and, afterwards in 1918, when the Dunsterville force had to fight its way to Pahlavi, strongly opposed by Kuchak Khan.

RESIDENCE, in general, a place of abode. In law, it usually means continuance in a place. The ordinary meaning of the word has been defined as "the place where an individual eats, drinks and sleeps, or where his family or his servants eat, drink and sleep" (*R.* v. *North Curry,* 1825, 4 B. & C. 959). For certain purposes, however, a man may be said to have his residence not only where he sleeps, but also at his place of business. (*See* ABODE; DOMICIL.)

RESIDENT, a political agent or officer representing the Indian government in certain native states in India; he resides in the state and advises on all matters of government, legislative or executive. In certain other dependencies or protectorates of the British Empire the representative of the government is termed a resident or political agent, notably in Nepāl, Aden, Sarawak, British North Borneo, etc. In general, where the state to which a resident is attached is not an independent one, he exercises consular and magisterial functions.

For "Resident" as the title of a diplomatic agent *see* DIPLOMACY.

RESINS. A natural resin is a sticky substance exuded in brown gummy drops by trees (Greek ῥέειν, to flow), especially pines and firs. These drops gradually harden in the air and form what most people recognize as a resin. Rosin, the commonest type of resin, is well known as a material for treating violin bows. Resins of industrial importance are obtained from trees of varied types growing in different parts of the world. Varnishes contain resin as an important constituent, and the long established connection between resins and varnishes is seen in the derivation of the word varnish, which has been considered to originate from *Berenice,* the golden-haired queen of Cyrene (mediaeval Latin, *verenice* and *vernis*) whose name the Greeks applied to the golden-coloured amber, a resin now mainly employed for beads and decorative ware, but used in earlier times for varnish.

I. NATURAL RESINS

The natural resins are mostly obtained by collecting the gummy substance which exudes from cuts made in the bark of the tree; some are fossil in origin, being found in a hard condition buried in the ground; shellac is distinct in being formed as a secretion by insects feeding on certain trees. There are also other sticky secretions of trees known particularly as *gums.* True gums, as distinct from resins, are soluble in water, as, for example, *gum arabic* (*q.v.*) used for making adhesives. The term resin is technically restricted to products which are insoluble in water but which will dissolve in liquids like methylated spirit, or which by special treatment will dissolve in oils, like linseed oil and turpentine, to form varnishes. To differentiate clearly between such resins (which are also spoken of as "gums" by the varnish maker) and the water-soluble gums, the former are often referred to more definitely as varnish resins.

Properties and Classification.—Varnish resins are to be recognized by their transparency and translucency, their brittleness and glass-like fracture, and the brown or yellow colour. They possess as a rule no taste or smell in the solid condition; on heating, they melt or soften and finally burn with a smoky flame giving an aromatic odour. Solutions of such resins can be made in methylated spirit, turpentine and other essential oils. In using resins with oils, such as linseed oil, a special treatment of the resin, known as "running," is usually necessary in order to make it soluble; this involves heating in the molten condition for some time, when some decomposition and loss of weight occurs, and the resin is considered to assume a simpler molecular structure, undergoing what is known as a depolymerizing process, thus becoming more readily soluble in the oil.

Solubility and hardness are the chief criteria used technically in classifying a resin, and on these lines resins may be divided into:—

Spirit-soluble resins which are (1) soft, such as the balsams and Burgundy pitch; (2) medium, such as mastic; (3) hard, such as damar, sandarac and shellac.

Oil-soluble resins which are (1) soft, such as some Manila copals; (2) medium, such as Kauri copal; (3) hard, such as Zanzibar copal and amber.

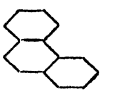
Much overlapping necessarily occurs in such a classification.

The Spirit-soluble Resins.—As the name *balsam,* or balm, suggests, these resins, of a fluid character, are of chief use as healing preparations in pharmacy. They are also called oleo-resins, containing a large proportion of volatile essential oil which usually consists of esters of cinnamic or benzoic acid. A hard

resin can as a rule be obtained from balsams by evaporating the essential oil. Turpentine, for example, as obtained from the tree, is an oleo-resin which yields solid rosin by evaporating or distilling away the essential oil of turpentine. Burgundy pitch, from Bordeaux turpentine, is used in medical plasters. Elemi is a fluid or semi-solid balsam, in a condition approaching that of an ordinary solid resin; it is sometimes used in special spirit varnishes.

A medium resin, such as *mastic*, is still of a soft nature but not fluid like the oleo-resins. It is mainly used in the preparation of high-grade varnishes of pale colour for the protection of paintings. It is obtained from one of the islands in the Grecian archipelago, from a tree of the Pistachia genus. A solution of mastic in turpentine, with linseed oil added, produces the artist's medium known as "megilp." Mastic is soluble in alcohol to the extent of about 90%, and melts at about 95° C. *Acaroid* or gum accroides, melting at about 100° C, is obtained from the Australian grass tree as a yellow or red resin. It contains phenolic compounds which give it medicinal value as a tincture suitable for treating affections of the mucous membrane. The crimson-red resin known as *Dragon's Blood* exudes from the fruits of the rattan palm, growing in the East Indies. It was used as a varnish by Italian violin makers.

Among the hard resins, *damar* is usually met with in the form of clear pale yellow nodules (melting point about 140° C), although varieties of various colours are collected. It is obtained from coniferous trees of the Dipterocarpaceae family in the Malay States. Damar varnish is prepared as a solution in turpentine, in which about 30% of the resin dissolves. It can be used as a paper varnish on account of its lustre and pale colour. North African and Australian cypress pines are the source of *sandarac*, a hard resin from which a colourless spirit varnish can be produced, suitable for coating paper labels, leather, wood and metals. It melts between 135° C and 145° C, after previous softening at about 100° C. It is completely soluble in ether and methylated spirit, but only slightly soluble in turpentine, benzene and petrol.



Shellac requires an animal intermediary for its production, thus differentiating this resin from other natural resins. Insects (*Tachardia lacca*), belonging to the Coccidae or scale insects, attach themselves for feeding purposes to certain Indian trees of the acacia family, and produce a scaly covering consisting of an amber-like material, which is the basis of lac or shellac. This resinous secretion is ground, washed and filtered, by squeezing while hot and molten through a cotton bag, on to hot plates or water-cooled rollers from which it is removed in the familiar flaky form. Lac is one of the most widely used resins in industry, providing an electrical insulating material, a stiffening agent for felt hats, etc., a preservative coating for wood and metal, and a binding agent for moulding compositions. The gramophone record industry absorbs about 60% of the output of shellac. It is marketed in various grades and under various descriptions, *e.g.*, stick lac, seed lac, button lac and garnet lac. The bulk of the shellac manufactured bears the mark "T.N.," a term the origin of which is lost in antiquity, although presumably the letters are the initials of an early manufacturer. The melting point lies between 77° C and 82° C. Chemically, shellac consists largely of esters of aleuritic acid, $HO{\cdot}CH_2{\cdot}(CH_2)_5{\cdot}CH(OH){\cdot}CH(OH){\cdot}(CH_2)_7{\cdot}COOH$, together with a red colouring matter, wax and moisture. It dissolves in methylated spirit forming a cloudy solution which clarifies on standing. For hat-stiffening, shellac is dissolved in a water solution of borax. A white shellac can be obtained by a bleaching process, from which colourless transparent lacquers can be made.

The Oil-soluble Resins.—Useful varnishes can be made with *rosin* and China wood oil, an oil of somewhat similar character to linseed oil. Soap and paper-making are also responsible for the consumption of considerable quantities of rosin. Compounds of rosin with certain metals known as resinates provide the important ingredients in paint and varnish called "driers" (*see* VARNISH). Rosin as the sole resin basis of a varnish is not desirable on account of its susceptibility to the action of air and moisture. It is used as a flux in melting the harder resins and preparing them for use in varnishes.

French rosin is obtained from the *Pinus maritima*. The flow of oleo-resin is stimulated by cutting the bark in a manner systematically controlled as to size of incision, position on the tree trunk, and season at which the cutting takes place. One tree can be made to yield rosin for three or four years, after which several years' rest are given. The annual production in France of rosin is about 100,000 tons, and turpentine 25,000 tons. American products are obtained from various kinds of pine grown in the south-eastern portions of the United States. The long leaf pine, *Pinus palustris*, is the most important.

Rosin remains in the still after removing, by distillation (*q.v.*) in the presence of water, the turpentine spirit or essential oil of turpentine from the oleo-resin exudation. The vapours liberated are condensed into two layers, one of turpentine and the other of water. The best grade of French rosin is clear and of a pale amber colour. American grades vary from WW (water white), WG (window-glass), through brown to black. The specific gravity of rosin lies between 1·070 and 1·080. Good qualities melt at 120°–135° C, and dissolve in all the usual solvents, except water.

Abietic acid, $C_{20}H_{30}O_2$, melting at 166° C, is the chief constituent of rosin, together with certain inert substances known as *resenes*. Current chemical opinion attributes a phenanthrene

nucleus (*see* CHEMISTRY: *Organic*, "Homocyclic Division") to resin acids of the abietic acid type. The properties of rosin as a varnish resin may be modified by heating with metallic oxides, such as lime or zinc oxide, or with glycerine, the products being known respectively as hardened rosin or ester gum. Rosin modified in these ways is present in spar, boat and other varnishes.

The *copals* form an important group of varnish resins (Spanish, from Mexican *copalli*, incense). They vary from soft to hard according to their age. Soft Manila copal collected direct from the tree is easily soluble in methylated spirit and oils, whilst the hard fossil varieties such as Pontianak require heat treatment before they can be mixed with linseed oil. Oil varnishes containing Manila resin are used for interior work. Kauri copal, melting at about 150° C, a valuable varnish resin from a New Zealand pine, is usually obtained as a fossil about 4 ft. underground, but sometimes is found buried as deep as 20 feet. The cheaper Congo copal, also a fossil resin, melting at about 200° C, is becoming a rival of Kauri. Sierra Leone copal, obtained by tapping the tree, and consequently not so hard as the fossil Congo copal, finds a use in making good pale-coloured varnishes. Zanzibar copal is one of the hardest resins used by the varnish maker, and is dug up now mostly from the mainland opposite the island of Zanzibar. Nodules of this resin, marked with distinctive "goose-flesh" markings, are found as a rule about 3 ft. in the ground. The melting point may be as high as 360° C.

Amber, the hardest resin known, is little used in the varnish industry. It is found in the ground in East Prussia, in the Baltic region, and efforts are being made in Germany to develop more fully the uses of this natural product.

Japanese and Chinese lacquer are obtained chiefly from the *Rhus vernicifera* (Urushi No-ki or Tsi-chou, varnish tree). The sap collected is a grey-brown viscous fluid, darkening in the air and forming a tough skin. A remarkably protective coating is obtained by using this fluid as a varnish. It is peculiar in requiring a moist atmosphere to enable the hardening process to take place. Chemically, the lacquer contains compounds of a phenolic character, of which urishiol $C_6H_3\begin{cases}OH(1)\\OH(2)\\C_{17}H_{37}(4)\end{cases}$, is the chief.

II. SYNTHETIC RESINS

Synthetic or artificial resins possess most of the physical characteristics of natural resins, and in addition may have, in certain types, the unique property of becoming infusible and insoluble after heat treatment. Chemically, a certain degree of resemblance is traceable between the phenolic synthetic resins and Japan lacquer and acaroid among natural resins, compounds of phenolic

character having been shown to be present in the latter products. Although produced by the chemical interaction of substances of definite composition, synthetic resins are usually of complicated and indeterminate composition. They are of industrial interest as substitutes for natural resins in the varnish industry, as insulating material in the electrical industry, and as a basis for the production of moulded articles for decorative purposes, such as umbrella handles, buttons, beads, brush backs, door-plates, knobs, etc.

Physical Classification.—It is possible to group synthetic resins according to solubility. There are resins which always remain soluble and those which are initially soluble but become finally insoluble under the action of heat, so called "heat-hardening" resins. The resins from formaldehyde and phenol, such as Bakelite, are of the latter class. Resins in the permanently soluble class may be further divided into (*a*) alcohol- or spirit-soluble resins, and (*b*) benzene- and oil-soluble resins.

The resins suitable for varnishes are either spirit-soluble (chiefly of formaldehyde-phenolic type), forming substitutes for shellac and the softer varnish resins; or oil-soluble (chiefly the coumarone type, and also modified formaldehyde-phenolic types), forming substitutes for hard natural resins. The modified oil-soluble formaldehyde-phenolic types referred to are produced from the spirit-soluble phenolic resins, by a process of melting with a natural resin akin to the "running" process adopted with natural resins.

Moulded Compositions.—Artificial resins are used extensively in preparing moulding compositions. Moulding resins, usually of heat-hardening phenolic type, are used either as pure unmixed resin, producing as a rule transparent mouldings, or incorporated with some inert "filling" material, such as sawdust, asbestos or clay, and pressed in heated moulds; or they may be used for impregnating paper or woven fabrics. By submitting these preparations to a process of pressing in heated moulds, highly durable mouldings in almost any desired form can be obtained. In order to give them maximum resistance to heat, chemical action and electrical forces, the mouldings, on removal from the moulds, are baked further, thus completing the chemical reaction in the resin. A material of considerable value for insulating purposes in the electrical industry is thereby obtained. The electrical properties are somewhat similar to those of ebonite.

Moulding compositions can also be prepared in a form suitable for the production of domestic articles, cups and saucers, bowls and plates, and the like. Textile materials can be decorated with beads made from artificial resin. Numerous other decorative uses are continually being found for artificial resins.

Chemical Classification.—Two main classes may be distinguished, (*a*) condensation resins, such as those of the formaldehyde-phenolic type, condensation being, in its simplest form, the chemical process whereby molecules unite, with elimination of water; (*b*) polymerization resins, such as those of the coumarone type. Polymerization is the chemical process in which relatively simple molecules of a compound become complex by combination amongst themselves. The term "polymerization resin" is used to distinguish a resin which is formed directly by the polymerization of a chemical compound, without passing through a preliminary stage of condensation. Polymerization is usually initiated by the action of light, heat, strong acids or alkalis.

Formaldehyde-phenolic Resins.—*Bakelite*, invented by L. H. Baekeland in 1909, is the leading representative of one main class of synthetic resins produced to-day in most countries in one form or another. The preparation involves the interaction of phenolic substances, such as phenol (*see* CARBOLIC ACID) and cresol (*q.v.*), with aldehydes, particularly formaldehyde (*q.v.*). The output of such resins and their derivative moulding compositions is a growing one. In America alone nearly 7,000 tons were manufactured in 1925, representing double the production of 1922. Other countries, of which Germany, France and Great Britain are the chief, manufacture something like an equal amount between them.

The process of manufacture is one of condensation, usually facilitated by the use of a small addition of acid or alkali. The details of one method of procedure are as follows: Equal parts of pure phenol and formaldehyde solution (formalin) with a small quantity of caustic soda are heated together in a steam-jacketed pan with stirring gear. The mixture gradually becomes cloudy and finally an oily layer separates. This layer is removed, and from it, by further heating, sometimes under diminished pressure, a molten resin is obtained. This resin, on cooling, sets to a brittle, transparent product. In this condition it is ready for dissolving in alcohol for use as an impregnating solution for sawdust or other "filler," to form moulding compositions. Mouldings made by pressing such a composition are then baked to bring about the final change to the inert resistant condition.

The simplest condensation products of phenol and formaldehyde are saligenin or *o*-hydroxybenzyl alcohol and *p*-hydroxybenzyl alcohol. Further mutual condensation of these compounds leads to a syrupy product which, on continued heating, gives a resin somewhat akin to Bakelite. No definite conclusions have yet been made as to chemical constitution, owing to the small reactivity of the resin in its final form. The fully polymerized formaldehyde-phenolic resin is insoluble in all the usual solvents and chemical reagents, except nitric acid and caustic alkali. It is more than probable that the final fully polymerized resin, prepared industrially, contains, in addition to a polymerized molecule of high molecular weight, a mixture of other substances, which are retained by the resin during hardening, such as free phenols and formaldehyde and crystalline intermediates formed during the condensation reaction. A number of mouldings are made with resins of the Bakelite type. A variety of useful mouldings are obtained from wood-meal-resin moulding composition, and also from laminated resin-paper and fabric compositions. The advantages of this type of material consist in its power to withstand temperatures at which rubber, ebonite, celluloid and natural resins soften and liquefy, or even decompose, together with the accuracy and high finish of the mouldings. For electrical insulation it is used in wireless apparatus, telephones, electric lamp sockets, generators, transformers and other electrical equipment. Paper or woven fabric compositions have been used for silent transmission gears and also, experimentally, for aeroplane propellers. Grinding wheels containing resin and emery, and self-lubricating bearings containing resin and graphite, can be built up. Laboratory apparatus for handling corrosive acids, especially hydrofluoric acid, has also been made.

Modified Formaldehyde-phenolic Resins.—The German *Albertols* and American *Amberols* are soluble in linseed oil and are prepared from formaldehyde-phenolic resins by heating with common rosin. They are now being further modified by the inventors by neutralizing the acidic part of the rosin component with glycerin. One such modified resin softens at 100° C and melts at 120° C, whereas the rosin used in its preparation softened at 59° C and melted at 65° C. These resins are used mostly as substitutes for oil-soluble natural resins in varnishes, although some varieties are proposed for the replacement of shellac in the preparation of bonded mica sheets, such as micanite. Certain formaldehyde-phenolic resins containing sulphur have some application in electrical insulation; *thiolite*, a resin of French origin, is prepared by the action of sulphur chloride on a condensation product of formaldehyde and cresol. It contains 12% of sulphur.

Formaldehyde-urea Resins.—Formaldehyde may also be condensed with urea, or its sulphur analogue, *thiourea*. Thiourea can be made from a by-product in gas manufacture. Opaque or transparent colourless resins are produced which, by continued heating, become insoluble. They are finding application in Great Britain, particularly the *Beetle* resin, in moulding powders from which table and decorative ware, very artistically tinted with delicate colours, can be produced. The transparent variety, particularly the German *Pollopas*, is proposed for use as a substitute for glass in motor-car wind-screens. Efforts are being made to render them suitable for electrical insulation. The moulded tableware can be washed with soap or weak soda solution without ill effect, and will stand temperatures of 110°–120° C. The specific gravity varies from 1·4–1·5. The chemical basis of this form of resin is probably a dimethylol derivative of urea or thiourea.

Glycerin Resins.—Glycerin and phthalic anhydride (*q.v.*)

react to give a resin of industrial interest, which in America is known as *Glyptal.* It is transparent, pale yellow and soluble in acetone, but becomes insoluble on heating to 220° C. In the insoluble condition it retains some degree of flexibility and finds application in the electrical industry, especially for amalgamating mica flakes to form insulating sheets. Such sheets when properly prepared compare favourably in electrical properties with similar sheets in which shellac is used as the binding resin. Pure *acrolein,* obtained from glycerin, is polymerized in the cold by the addition of an alkali, forming a white powder melting between 80° C and 100° C. It can be dissolved in alcohol and used as a varnish. Acrolein also reacts with phenol to form a hard resin in the presence of about 1% of caustic soda. These resins of French origin have electrical properties of the order of those of ebonite. An American resin, *acrolite,* can be prepared from glycerin and phenol by heating to between 160° C and 190° C, in the presence of a small quantity of sulphuric acid.

Coumarone Resins.—Coumarone resins are prepared from certain fractions distilled from coal-tar naphtha, and are used in varnishes, and also to some extent as softening agents in rubber mixing. Their method of production involves no preliminary condensation but consists in direct polymerization of coumarone, indene and unsaturated cyclic compounds of this class, contained in the naphtha distillate, by means of strong sulphuric acid. They vary in colour from light yellow to black. They are miscible with drying oils and will dissolve in benzene but not in alcohol.

RESISTANCE, MEASUREMENT OF. That bodies offer resistance to the passage of the electric current through them is shown by the heat developed when the current passes. This heat production was made the basis of a method of comparison by Henley (1774) and Nairne (1780) who concluded from his experiments that "iron wire resists the passage of the electric fluid much more than copper." (*Phil. Trans.* [Hutton] *14* p. 688.) Davy (*Phil. Trans.,* 1821, p. 430) showed that the conducting power of wires is proportional to their cross-sectional area divided by their length, but exact ideas were lacking until the importance of Ohm's Law (1827) was appreciated. An absolute unit of resistance could then be defined as the resistance of a conductor in which unit potential difference produces unit current.

The practical unit of resistance is the International Standard Ohm defined (1894 and 1908) as "the resistance offered to an invariable electric current by a column of mercury at the temperature of melting ice, 14·4521 grammes in mass, of a constant cross-sectional area, and a length of 106·300 centimetres." This unit is equal to about $1{\cdot}0005\times10^9$ absolute C.G.S. units. The megohm is one million ohms, and the microhm one millionth of an ohm. Specific resistance, or resistivity, is defined by ρ in the equation

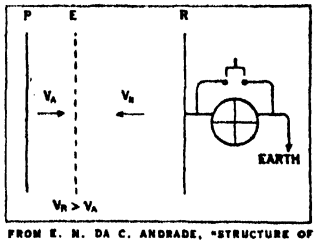
$$\text{Resistance} = \rho\,\frac{\text{length}}{\text{area of cross-section}}$$

and is therefore measured in ohm-cm.

The practical measurement of resistivity involves many processes and instruments (*see* INSTRUMENTS, ELECTRICAL); but the methods employed may be classified as Comparison Methods and Absolute Methods. In the former a comparison is effected between the resistance of the material in a known form and some standard resistance, in the latter, the resistivity is determined with reference to the fundamental units of length, mass and time. Special methods are required to determine the resistance of insulating materials and of electrolytes. (*See* INSTRUMENTS, ELECTRICAL; ELECTROLYSIS; ELECTRICITY, CONDUCTION OF: *Solids.*)

RESONANCE, a term used in physics and related fields denoting a prolongation or increase of sound due to sympathetic vibration of some body capable of moving in the proper period. An illustration of resonance is seen when two heavy pendulums of the same period are mounted upon a wooden frame which yields slightly to their motion and one pendulum is set vibrating. In a few minutes it will be seen that the second pendulum is acquiring vibratory motion through the support. Its motion gradually increases until the two are swinging with equal amplitude but with a phase difference of a quarter period. The second pendulum continues to lag behind the first, gradually absorbing its energy until the first is brought to rest, after which the phenomenon is repeated in the reverse order. *See* PHYSICS, ARTICLES ON. The counterpart of this phenomenon is applied to electricity (*q.v.*). *See* ELECTRIC WAVES and articles related to radio.

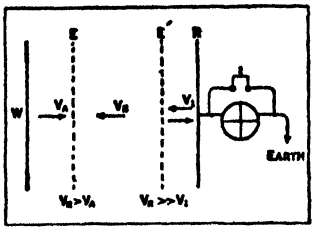
RESONANCE POTENTIALS. We are brought to the consideration of resonance potentials, which are also called critical potentials or excitation potentials, by the consideration of the passage of an electron through a gas. We must first premise that the energy, and consequently the velocity, of an electron is usually expressed in volts, a velocity of so many volts meaning the velocity which an electron would acquire in moving *freely* through a potential difference of that number of volts. It has been established by the experiments of J. Franck and G. Hertz that electrons of small energy, *i.e.,* with velocities of a few volts only, behave like minute gas atoms when they strike a gaseous atom. The impact follows the laws of the impact between two perfectly elastic spheres, the electron bouncing off with practically no loss of velocity, since the mass of the gas atom is relatively so great. When we are considering the passage of electrons through inert gases, metallic vapours of small electron affinity, and certain other gases, it is found, however, that, as the velocity of the electrons is raised, a certain critical value is reached; for all velocities greater than this critical velocity the electron loses a definite amount of energy in the collision, or makes what is known as an inelastic impact. The kinetic energy so lost goes temporarily to increase the internal energy of the atom, and ultimately appears in some other form. If the velocity of the electron be further increased the loss of energy at impact remains the same until a step is reached when another sudden loss of energy takes place on impact, this time of greater magnitude. In general, as the potential which accelerates the electron is increased a series of values will be found, at each of which a different type of inelastic collision with the gaseous atom first takes place. These particular values are the resonance potentials characteristic of the gas in question: they vary in magnitude from gas to gas. Finally, a potential can be found which gives the electron sufficient energy for it to be able to ionise the gas atom which it strikes, that is, displace an electron from it. This potential is the *ionisation potential* of the gas.



Theoretical Importance of Resonance Potentials.—The resonance potentials have assumed great importance in modern physics from the direct confirmation which they give of the most fundamental assumption of Bohr's theory of atomic structure. (*See* ATOM, QUANTUM THEORY.) On this theory an atom can exist in a series of stable states—or stationary states, as they are called —to each of which pertains a given energy, but cannot exist in any state of energy intermediate between these. We can get a picture of these states by assuming that the electrons of the atomic structures have certain preferential orbits, to each one of which corresponds a certain energy of the atom (*see* ATOM), but this picture is not indispensable for our present purpose. To transform the atom from its normal state, of energy E, to a stationary state of greater energy E′, clearly demands a certain input of energy: when the atom returns from this excited state to its normal state —either in one step or more steps—the energy is given out again, in general in the form of radiation (in general, because it is possible for the energy to appear as kinetic energy of another particle), the frequency of the radiation being given by

$$h\nu = E' - E$$

where h is Planck's constant, ν the frequency. We should therefore expect that if an electron strikes an atom, and its energy is less than that required to raise the atom to the first stationary state above the normal, it will be unable to communicate any-



thing to the internal energy of the atom, and will spring off elastically. If, however, the energy E_e of the electron in question equals or exceeds E'_1—E, where E'_1 is the energy of the first stationary state, it can raise the atom to that stationary state, and will proceed after the collision with diminished energy $E_e-(E'_1-E)$. We neglect the kinetic energy communicated to the atom as a whole, since, on account of the great mass of the atom, this is negligible. Similarly, if the energy of the electron exceeds E'_2-E, when E'_2 is the energy of the second stationary state, the electron can raise the atom to that state, experiencing itself a correspondingly greater loss of energy. In the first case the atom, on returning to its normal state, should emit the first spectral line of a series, in the second case the second line, of higher frequency, and higher critical potentials should be able to excite lines of still higher frequency. The resonance potentials therefore provide a double experimental check on Bohr's hypothesis. In the first place we can, by electrical methods, measure the velocity of the electron before and after impact with the gas atom, observe at what potentials the abrupt losses of velocity take place, and compare these potentials with those to be anticipated from the known values of $h\nu$ for the appropriate lines of the spectrum of the atom. In the second place we can observe the radiations from the gas which attend the passage of electrons of different velocities, and find out at what potentials the different lines first appear—*i.e.*, we can carry out the so-called step-by-step excitation of spectra, and measure the excitation potentials. Both methods lead to brilliant quantitative confirmation of Bohr's hypothesis of stationary states, and of the quantum theory of spectral series. The electrons lose energy in steps, at the stages to be anticipated from the theory, and the spectral lines appear in turn at the potentials calculated.

Experimental Methods.—The pioneer worker on the subject was Lenard, who in 1902, long before Bohr's theory was put forward, showed that an electron must possess a minimum energy before it can produce ionisation in a gas. He released the electrons from a metal plate P photoelectrically (*see* PHOTOELECTRICITY), and accelerated them by means of a parallel gauze E maintained at the desired potential, the gas pressure being low enough for the greater part of the electrons to pass through the space between P and E without a collision (fig. 1). He detected the formation of ions by means of a plate R, charged negatively, so that, while electrons cannot reach it direct, any positive ions formed are at once attracted, and make their presence known by a sudden change in the current from R. In this way he found that no ions were produced unless the accelerating potential exceeded a certain threshold value. However, as pointed out by Bohr and van der Bijl, a change in the current from R does not necessarily indicate ionisation in the gas between E and R, for if the electron impact is not sufficiently energetic to make the atoms struck lose an electron, but merely makes them emit radiation, then this radiation will act photoelectrically on the plate R, causing it to lose electrons. As far as current effects go, loss of electrons by R or gain of positive ions by R come to the same thing. Lenard's original method has therefore been modified in various ways, to enable a distinction to be made between a resonance potential and an ionisation potential. It is also usual nowadays to produce the electrons by means of a hot wire (*see* THERMIONICS) instead of photoelectrically. Davis and Goucher introduced a second gauze E′ (fig. 2) and arranged the potentials as follows: a potential V_R, greater than the accelerating potential V_A, acts so as to stop the electrons reaching R, while a small potential V_1, which can be reversed, is maintained between E′ and R. When E′ is negative to R photoelectric electrons cannot escape from R, when E′ is positive to R they can, so that the photoelectric effect of radiation on R can be detected at once. Reversal of the direction of the small field between E′ and R has, however, little effect on the passage of positive ions to R, because these are accelerated by a comparatively large potential fall, and have sufficient energy to overcome the opposing field. In this way radiation potential and ionisation potential can be clearly distinguished. Lenard's method has also been modified by Franck and Hertz in a famous series of experiments which dealt especially with the resonance potentials of mercury vapour. This vapour has yielded particularly clear confirmation of Bohr's theory. There are, for instance, resonance potentials at 4·9 volts and 6·7 volts. The wave-lengths which correspond, on the quantum theory of spectra, to these potentials can be calculated from the fundamental equation

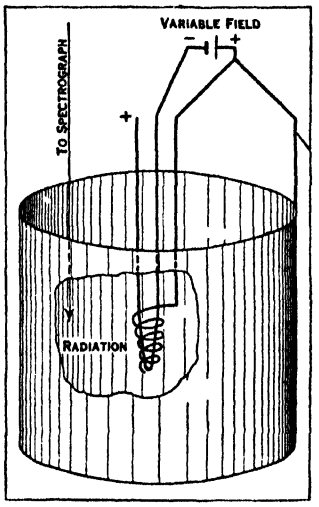

FIG. 2.—GOUCHER'S ARRANGEMENT FOR DISTINGUISHING RESONANCE POTENTIALS AND IONISATION POTENTIALS

$$\text{energy} = eV\frac{1}{300} = h\nu = \frac{hc}{\lambda}$$

when e is the electronic charge, V the potential *in volts*, h is Planck's constant, c the velocity of light, λ the wave length. To 4·9 volts corresponds a wave-length of 2520 Å.U., to 6·7 volts a wave-length of 1844 Å.U., which agree, within the experimental error of these measurements, with 2536 Å.U. and 1849 Å.U., the wave-lengths of the two strong lines of the mercury spectrum to be anticipated on the theory.

G. Hertz has more recently worked out some very delicate methods of measuring both resonance and ionisation potentials. One of the methods detects, by a skilful disposition of the gauzes, the abrupt loss of velocity of electrons which takes place when the accelerating potential reaches a critical value: this method therefore measures radiation potentials. The other method depends upon an annulment of the so-called space charge, which surrounds a hot wire, by the positive ions produced when, but not before, the accelerated electrons have sufficient energy: this method clearly detects ionisation potentials.

A different type of experiment, that which relies on the excited radiation for a sign that the resonance potential has been reached, is represented by the work of Foote, Meggers, and Mohler. They use the disposition represented in fig. 3. The electrons are produced, as usual, by a hot wire, here of hairpin shape, and accelerated by the field between the wire and the grid, constituted by a close spiral coil. The comparatively large cylinder which surrounds the grid is kept at the same potential as the grid. The region in which the electrons are accelerated is narrow, so that there is little chance of an impact which would prevent an electron attaining its full velocity: the region between the grid and plate is wide, so as to give plenty of opportunity for impacts to produce radiation. The accelerating potential is varied, and the values at which individual spectral lines appear carefully noted. The study of resonance potentials in this way was initiated by Franck and Hertz, who observed the potential which was just sufficient to excite the well-known mercury line of wave-length 2536 Å.U. They were followed by McLennan and his students, who showed that either one or two lines or the whole series could be excited, according to the potential. Since then other workers, notably Newman, have succeeded

FROM ANDRADE, "STRUCTURE OF THE ATOM" (BELL)

FIG. 3.—APPARATUS FOR MEASURING RESONANCE POTENTIALS, AS DEVISED BY FOOTE, MEGGERS AND MOHLER

in producing certain spectral series line by line, each new line first appearing at the potential indicated by Bohr's theory.

All these experiments clearly show that energy can be communicated to atoms in definite amounts only, and that the communication of a definite amount of energy to an atom is followed by the emission of a spectral line or lines, the wave-length of these lines being connected with the energy communicated exactly as indicated by the quantum theory of spectra. It should be added that not only can one electron be completely removed from an atom at the ionisation potential, but that a higher potential can be measured which suffices to remove two electrons, and so excite the so-called spark spectrum. (*See* SPECTROSCOPY.)

Applications of the Theory of Resonance Potentials.—The established fact that a perfectly definite energy is needed to excite any given spectral line, or to separate an electron from an atom and so ionise it, has found wide application. The energy with which one atom strikes another at room temperatures is far below that which corresponds to the first resonance potential of any gas, and so we can expect no luminosity of gases at ordinary temperatures. In a flame the temperature is already sufficient for an appreciable fraction of the atoms to collide with sufficient energy to excite spectral lines. If metal atoms are introduced into a flame, the lines which are detected at the lowest temperatures are the lines with the lowest excitation potentials, and as the temperature of the flame is raised more and more lines appear, in accordance with the theory, the increased energy of the atomic impacts corresponding to the increased energy of electron impact which we get as we raise the potential. Again, elements with spectra of low resonance potentials show in the flame more lines at a given temperature than those with high resonance potentials. More striking still are applications of the conception of ionisation and resonance potentials to astrophysical problems. By considering the ionisation of an atom as a chemical problem, in which the ionisation potential takes the place of the heat of dissociation, Saha has worked out the percentage ionisation to be expected under different conditions of temperatures and pressure, and applied his result to the spectrum of the sun, with very interesting results. He has especially considered the ionisation of calcium atoms in the sun's atmosphere, and explained many peculiarities of the apparent distribution of the element. This work has been much extended, especially by R. H. Fowler and E. A. Milne. (*See* STAR.)

RESORCINOL, one of the three dihydric phenols (*q.v.*), was first obtained by Hlasiwetz and Barth (1864) by the potash fusion of certain natural resins (galbanum, asafoetida, etc.). It crystallises in colourless, odourless plates or rhombic prisms having a sweet taste; it melts at 118° and boils at 178°/16 mm. or at 276·5° C/760 mm. Its specific gravity is 1·2717, and 100 parts of water dissolve 147 parts at 12·5° C. It is an important intermediate in the colour industry and for this purpose is prepared synthetically from benzene. This hydrocarbon is sulphonated with fuming sulphuric acid to benzene *meta*-disulphonic acid and the sodium salt of this acid is heated with caustic soda or potash (2½ parts) containing a little water to 270° C for 8 to 9 hours. The cooled fusion is dissolved in water, acidified with hydrochloric acid and extracted with amyl alcohol or preferably ether. After distilling off the solvent from the extract the resorcinol is obtained by distillation *in vacuo* and purified by sublimation or by crystallisation from benzene. It is also called resorcin, and is m-dihydroxybenzene, $C_6H_4(OH)_2$.

Use in Dye Manufacture.—Resorcinol is largely employed in the manufacture of xanthone dyes. When heated with phthalic anhydride it furnishes fluorescein which on bromination and iodination yields the dyes eosin and erythrosin respectively. It couples with many diazo-compounds giving rise to technically important azo-dyes. Its dinitroso-compound is Fast Green or Alsace Green. Resorcinol serves as a developer in dyeing and printing. By heating with ammonia under pressure resorcinol is converted into *meta*-aminophenol, a dye component, and the substitution of ammonia by the alkylamines and dialkylamines in the autoclave leads to the production of mono- and di-alkyl-*meta*-aminophenols, these substances being essential intermediates in the manufacture of the rhodamine series of colouring matters. (*See* DYES, SYNTHETIC.)

Resorcinol has had varied uses in medicine. It possesses valuable antiseptic properties. In weak solution it is non-irritant to the skin and is used up to 5 or 10% in ointments for chronic skin diseases such as psoriasis, eczema and ichthyosis. Epithelioma and rodent ulcer have been treated with resorcinol ointments and plasters and it is applied locally to condylomata and mucous patches. When formerly employed in the United States as an antiseptic, the dose was 2 to 8 grains. A 2% solution is used as a spray in hay fever and whooping cough. In large doses resorcinol is a poison causing giddiness, deafness, salivation, sweating and convulsions. When applied externally to large surfaces it has proved dangerous and even fatal.

Resorcinol monacetate, prepared by the action of acetyl chloride, is used under the name of euresol in a 10 to 30% acetone solution in the treatment of acne, dandruff, seborrhoea and sycosis.

For the detection of resorcinol the fluorescein reaction is the most delicate. Bromine produces a precipitate of tribromoresorcinol. Formaldehyde in hydrochloric acid gives an insoluble amorphous condensation product with an aqueous solution containing 0·001% of resorcinol.

(G. T. M.)

RESPIGHI, OTTORINO (1879–), Italian composer, was born at Bologna on July 9, 1879, and studied at the Liceo of Bologna, at St. Petersburg (Leningrad), under Rimsky-Korsakov, and in Berlin under Max Bruch. In 1913 he was made professor at the Royal Liceo di S. Cecilia in Rome, and in 1923 director. The operas *Semirama* (1910) and *La bella addormentata* (1922) were followed by the successful *Belfagor* (1923), which reflects in the eclecticism of its style the cosmopolitan character of the composer's training. His orchestral music includes the symphonic poems *Aretusa* (1911), *Le fontane di Roma* (1916) and *Pini di Roma* (1924); in the way of chamber music he has written a sonata for violin and pianoforte, and two string quartets, while a "concerto Gregoriana" for violin and orchestra may also be mentioned.

RESPIRATION. The conception of life is so closely bound up with that of respiration that the very word "expiration" has come to connote the extinction of life, and "inspiration" its elevation to a super-human level. Respiration is a process common to all forms of animal life, the reason for which is that the chemical basis of life is essentially an oxidation of tissue. Rightly, we speak of the "flame" of life, for in the body, as in the fire, material is all the while being consumed, with concurrent consumption of oxygen, and the production of carbon dioxide. Respiration consists essentially in the transport of oxygen from the air to the place where the oxygen is used up by the body, and the transport of carbon dioxide from the place where it is produced to the external air. Many animals, of course, live in water; indeed, life presumably began in that medium. But even for them the ultimate source of oxygen is the atmosphere; from it the water acquires fresh stocks of oxygen as the animals which inhabit it use up the gas. The oxygen in water is for the most part in solution, not in bubbles; but in the sea the constant breaking of the waves has a most potent effect in oxygenating the surface layers of the water.

In the most primitive forms of life respiration is very simple. In the amoeba, which is little more than a minute particle of jelly, the respiratory process is carried on in this way: The amoeba lives in water, from the water oxygen soaks into the body of this animalcule, where it is always being used up, and because it is always being so used the potential of oxygen inside the amoeba is always less than the potential of oxygen in the water outside. The oxygen, therefore, by a simple process of diffusion, is ever tending to migrate from the place of higher to that of lower

potential, *i.e.*, from the water to the interior of the amoeba, so a constant stream of gas is maintained. So also with the carbon dioxide; it is produced in the amoeba, from the interior of which it diffuses out, through the surface into the surrounding water.

In the higher forms of life, there is no different principle involved, so far as is known, from that of the amoeba. The apparatus for effecting respiration becomes more complicated, but the actual process is the same, namely, the *diffusion* of gas, oxygen or carbon dioxide from the place of higher to the place of lower potential.

THE SUPPLY OF BLOOD TO THE LUNG

The necessity for some definite system of transport arises partly from the greater size of animals as compared with the amoeba, and partly from the greater intensity of their oxidative processes. The inhabitants of an island a mile square would need no special transport system for the carriage of their fish, but the population of a continent does, and not only the mere machinery for moving the fish but all the accessory apparatus of cold storage and the rest for moving it in good condition. Moreover, if the continent be inhabited by persons with an insatiable craving for fish the capacity of the transport system must be correspondingly increased.

In the more lowly organized aquatic animals the system of transport is as follows: A circulation is maintained throughout the animal of fluid which differs little from seawater. At some point, known as the gill, this circulation comes very near to the surface, being only separated from the seawater by the wall of the vessel in which it is coursing. That wall is no thicker than the body of the amoeba, and so the gases, oxygen and carbon dioxide, have no difficulty in diffusing into and out of the circulating fluid. The amount of gas which can be dealt with depends principally on the extent of the surface of circulating fluid that can be exposed at any one time to the water. Therefore, for the purpose of creating the maximal surface, the gills of some creatures take on curious and feathery forms. Such are those of the lobster, which may be seen by breaking away the shell at the side. Indeed, the surface is so great that the water around the gill would be completely denuded of oxygen were there not a special mechanism for ensuring a constant circulation of fresh water, carrying a continuous supply of oxygen-charged water over the surface of the gill feathers.

The gill system of the lobster exhibits the principles on which the respiratory systems of almost all the higher animals are based, *i.e.*, the exposure of a large surface of fluid which circulates in the animal (the blood) to a corresponding large surface of either air or water which is constantly being replenished. The oxygen-containing medium and the circulating blood are not in actual contact, but are separated from one another by a membrane through which the oxygen (and carbon dioxide) must diffuse. One section of the animal kingdom has attempted a respiratory system on different lines, namely, the insects. In them the air is piped all over the interior body to, or almost to, the actual functioning cells. There is no intermediary circulating fluid. The whole tissues of the insects are therefore permeated by an elaborate system of tubes, the tracheae, with walls stiff enough to prevent their collapsing. The tracheal tubes are often extremely narrow in bore. This system has grave limitations. The rate at which gases can diffuse along very fine tubes is very slow, and sufficient oxygen can only penetrate, therefore, for a short length. No portion of the insect, therefore, can be far removed from the external air, and for that reason all insects are small; the largest development of which they seem capable is that of the dragon fly, which has a relatively long but extremely attenuated body. Developmentally the insects are side-tracked.

To return to the normal line of development, the principles of respiration are simply portrayed in such an air breathing animal as the newt (fig. 1*a*). Imagine a grape with a tubular stalk and with air inside the skin instead of fruit, and you have something like the lung of the newt. In the substance of the wall the blood circulates, a large surface being exposed in a close network of capillaries to the air in the lung, which air is intermittently forced in and out of the lung by swallowing movements on the part of the newt, the stalk of the lung (or trachea) being an outgrowth of the gullet.

Leaving for the moment the consideration of the circulating fluid, we may follow two other lines of development: (1) the mechanism for increasing the amount of surface of fluid exposed to air and (2) the mechanism for perfecting the ventilation of the lung.

Mechanism for Increasing Exposed Surface of Fluid.—In the lung of the frog a much larger surface of blood can be exposed than in that of the newt, for the inner surface of the lung is thrown up into ridges, called septa. These again give rise to secondary and even tertiary septa, as is shown in fig. 1*b*. All these septa are richly supplied with blood capillaries.

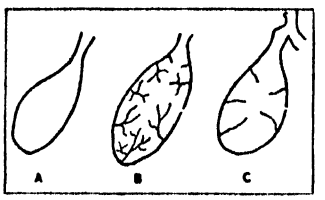

FIG. 1.—SCHEMATIC REPRESENTATION OF SECTIONS THROUGH LUNGS (A) Lung of the newt with no septa, (B) lung of frog showing primary, secondary and tertiary septa, (C) infundibulum of human lung showing primary septa

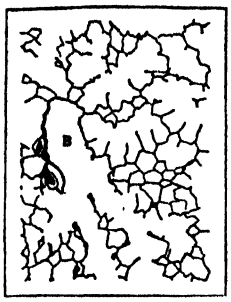
The lung of the warm blood animals is more complicated still. It may be likened, not to a grape, but to a bunch of grapes—indeed to several bunches of grapes. The unit corresponding to a single grape is called the infundibulum. That corresponding to a bunch the lobule. Each infundibulum is intermediate in structure between the whole lung of the newt and that of the frog. It contains septa, but only primary septa (fig. 1*c*). These divide the margin of the infundibulum into a number of chambers, the alveoli. The interior of the infundibulum is, therefore, a sort of honeycomb, the alveoli corresponding to the cells of the comb; indeed, they are often called the air cells. In microscopical sections of the lung the air cells are cut across in all sorts of quite irregular ways, but the general appearance much resembles that of a section of a rather broken honeycomb (fig. 2).

Before birth the whole lung is folded up, the opposing walls of the air cells are in contact with one another and there is, of course, no air in the lung. Such a lung will sink if thrown into water, in which respect it is in marked contrast to the normal organ. It is one of the abiding mysteries of creation, that, when the new born child expands his lungs for the first time, the whole system of lobulae, infundibula and alveoli unfolds and fills with air. From that time onwards air is always passing into and out of the lung. The quantity taken in at each respiration is called the tidal air and is normally about 300–550 cu cm. Of this about 150 cu.cm. never goes further than the respiratory passages; the remainder becomes mixed up with the air in the air cells (alveolar air) of which there is, perhaps, three litres in the lung. The following table gives the percentage composition of inspired and alveolar air:—

Component	CO_2	N_2	O_2	H_2O (vapour)
Inspired air . . .	0·04	79	20·94	1
Alveolar air . . .	5·3	74·1	14·4	6·2

There are several ways of measuring the composition of alveolar air. That of Haldane and Priestley consists of blowing with extreme suddenness and force down a rubber tube about 5 ft. in length and about 1 in. in diameter. The air from the respiratory passages passes first along the tube and is washed out by the air from the deeper parts of the lung. If the subject has emptied his lung to the maximum the tube, or at least, the portion next to his mouth will contain pure alveolar air. Immediately after the expiration, the tube is closed with the tongue. To it, about 1 in. from the mouth, is fitted a vacuous sampling tube; by the opening of a tap a sample of the air in the alveolar air tube can be taken into the sampling tube for analysis.



Residual air is the volume of air remaining in the chest after the most complete respiratory effort. It ranges from 1,600–2,100 cu.cm.

Reserve or *Supplemental Air* is the volume of air which can be expelled from the chest after an ordinary quiet respiration—about

1,500 cu.cm.

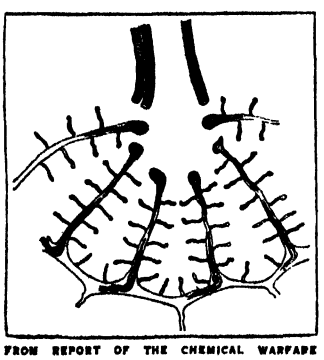
Complemental air is the volume of air that can be forcibly inspired over and above what is taken in by normal inspiration and is 1,600–2,100 cu.cm.

Vital capacity is the quantity of air which can be expelled from the lungs by the deepest possible expiration, after the deepest possible inspiration. It obviously includes the complemental, tidal and reserve airs. The vital capacity of 73 Air Force pilots in the British army, tabulated by Col. Flack, varied between 5,500 cu.cm. and 2,800 cu.cm. Considerable importance is attached to the vital capacity as an index of the suitability of pilots for high flying. *Vital capacity* is measured by means of a *spirometer*, a graduated gasometer into which air is blown from the lungs.

FROM REPORT OF THE CHEMICAL WARFARE COMMITTEE (H.M. STATIONERY OFFICE)

FIG. 2.—SECTION OF A NORMAL LUNG OF GOAT (B) The termination of a small branchiole

Lung Surface.—The whole surface presented by the walls of all the alveoli of a single human lung has been computed at about 1,000 sq.ft.; over the whole of this there is a compact network of capillaries, spread like a close pattern on a carpet. The blood in this vessel is separated from the air in the alveoli only by a membrane of almost inconceivable thinness.

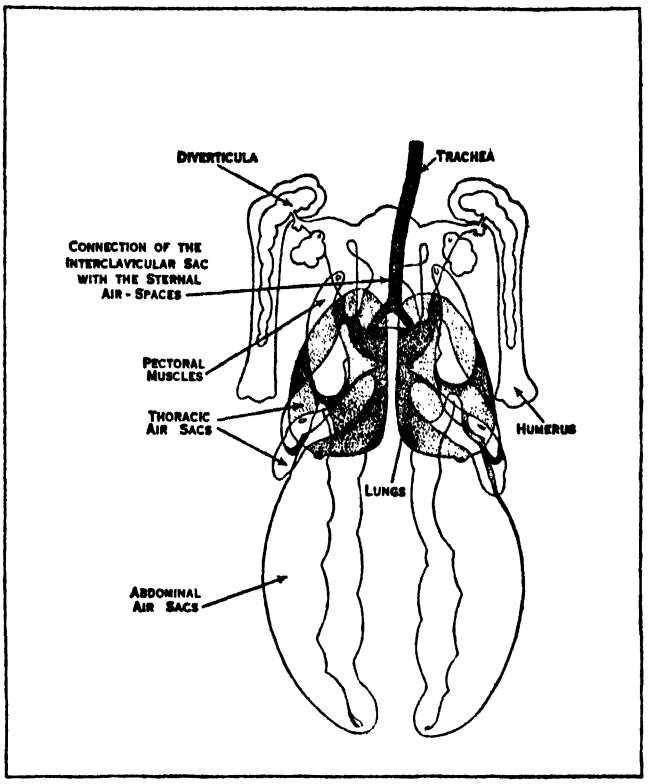


Minute Volume of Blood.—The quantity of blood which reaches the lung in man is variously computed as being from 3–7 litres per minute during rest, and may be increased probably to 20 or 30 litres per minute or even more during exercise and in athletic persons. This blood comes from the right side of the heart, along the pulmonary artery, and parts with about 50 cu.cm. of carbon dioxide per litre in its transit of the lung. Simultaneously it picks up about the same amount of oxygen or rather more.

Provision, therefore, is required for air to ventilate the lung in sufficient quantity to carry off about 250 cu.cm. of carbon dioxide per minute during rest, and to supply about 300 cu.cm. of oxygen. Moreover this oxygen must be contributed without so far depleting the air itself as seriously to reduce the rate of diffusion.

In practice, the level of carbon dioxide in air of the alveoli is not allowed to rise above 5·5%, nor the oxygen to sink below about 14% at the sea level.

THE SUPPLY OF AIR TO THE LUNG



To accomplish these ends a ventilation through the respiratory system of about 7 litres of air per minute must be maintained during rest, which may be increased up to something like 100 litres per minute during violent exercise. The primitive method of ventilation is quite inadequate for the needs of warm blooded animals. The frog carries out the following routine: (1) It fills its mouth with air; (2) closes its nostrils; (3) forces the air in the mouth into the lungs, which become distended; (4) opens the nostrils and lets out the air so that the lung partially collapses. Both the bird and the mammal have invoked the muscles of the body for the purpose of evolving special and efficient mechanisms by which to ventilate the lungs. Their mechanisms are, however, very different, not to say contrary. The bird, like the mammal, possesses a trachea which branches into bronchi, but whereas in the vertebrate each bronchus supplies one lung and that alone, in the birds each bronchus leads not only to a lung but to a series of air sacs which ramify over a great part of the body, even penetrating the bones (see *Diverticula* in fig. 3), which gives an idea of the size and situation of the air sacs. The function of the air sacs appears to the present author to be incompletely understood. The following quotation expresses the state of knowledge on the subject:—

FROM REPORT OF THE CHEMICAL WARFARE COMMITTEE (H.M. STATIONERY OFFICE)

FIG. 2A.—DIAGRAM OF BRONCHIOLAR TERMINATION OR ATRIUM WITH INFUNDIBULA OPENING OFF

"In the bird the chest does not exist as a separate chamber. Expiration is effected by the thoracic and abdominal muscles,

AFTER C. HEIDER, IN SEDGWICK, "STUDENT'S TEXT-BOOK OF ZOOLOGY" (ALLEN & UNWIN)

FIG. 3.—DIAGRAM OF THE LUNGS AND AIR SACS OF THE PIGEON

which compress the thorax and abdomen, driving the air from the air sacs, through the lungs and trachea. Inspiration is effected by the elastic expansion of the thorax and abdomen on relaxation of the muscles; this expansion causes an inrush of air along the

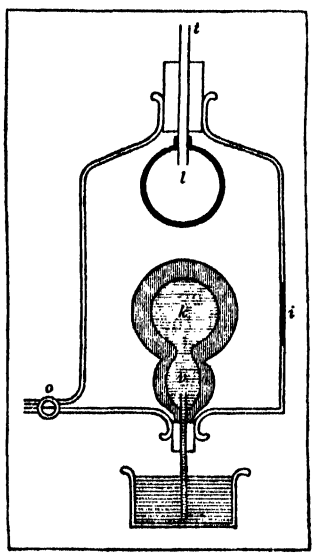


FIG. 4

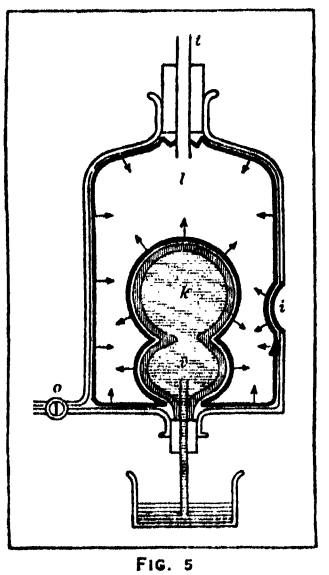

FIG. 5

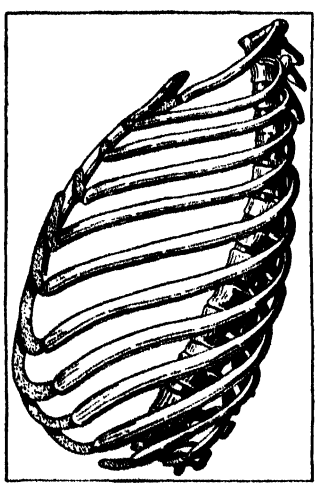

trachea and lungs into the air sacs, the lungs being thus filled with fresh air." The above description, given by Marshall and Hurst, refers to the bird at rest; when flying the movements of the wings probably have an important effect on inflating and deflating the chest.

Mechanics of Respiration.—The mammal has elaborated a very special mechanism for the inhalation and exhalation of air.

By means of the diaphragm the portion of the body cavity which contains the lungs, the heart and the great vessels is shut off from the rest. The thorax is practically a closed box entirely filled by the lungs, heart and other structures contained within it. If we were to freeze a dead body until all its tissues were rigid, and then were to remove a portion of the chest wall, we should observe that every corner of the thorax is accurately filled by some portion or other of its contents. If we were to perform the same operation of removing a part of the chest wall in a body not first frozen we should find, on the other hand, that the contents of the thorax are not by any means in such circumstances bulky enough to fill up the space provided for them. If we were to measure the organs carefully we should find that those which are hollow and whose cavities communicate with the regions outside the thorax are all larger in the frozen corpse than in that which was not frozen. In other words the organs in the thorax are distended somewhat in order that they may completely fill the chest cavity; and the nature of this curious and important condition may best be illustrated by the simple diagrams figs. 4 and 5 (from Hermann's *Physiologie des Menschen*) where *t* is the trachea, *l* the lung, *v* the auricle of the heart, *k* the ventricle, *i* an intercostal space with its flexible membranous covering. When the interior of the vessel is rendered vacuous by exhaustion through the tube *o*, the walls of the lungs and heart are expanded until the limits of the containing vessel are accurately filled, while all flexible portions of the walls of the vessel (corresponding to the intercostal membranes of the diaphragm of the thorax) are sucked inwards.

From this description it follows that the lungs, even when the thorax is most contracted, are constantly over-distended, and that when the cause of this over-distension is removed, the lungs, being elastic, collapse. It further follows that if the thorax is dilated, the flexible hollow organs it contains must perforce be still more distended—a distention which, in the case of the lungs, is followed by an indrawing of air through the trachea in all cases where the trachea is open. Thus, as the act of respiration is primarily a dilatation of the thorax, the part played by the lungs is, as Galen knew, a purely passive one.

How is dilatation of the thorax effected? It has been pointed out that the rib-planes decline from the horizontal in two directions, viz., from behind forwards, and from the antero-posterior mesial plane outwards; a glance at fig. 6 will make this double sloping clear to the reader. It has, moreover, been explained that the diaphragm arches upwards into the thorax in such a manner that the lateral parts of the arch are vertical and in contact with the inner face of the thoracic walls. This being the structure of the thorax, the enlargement of its cavity is brought about (1) by raising the rib-planes until they approach the horizontal, and (2) by depressing the diaphragm and making its rounded dome more cone-like in outline. A moment's consideration will show how these actions enlarge the boundaries of the thorax.

FROM HENLE, "HANDBUCH DER SYSTEMATISCHEN ANATOMIE" (VIEWEG & SOHN)

FIG. 6.—DIAGRAM SHOWING SLOPE OF RIBS

Nervous Mechanism of Respiration.—The chest, then, for purposes of respiration, consists of a box which dilates and contracts rhythmically; the actual rhythm is supplied by the nervous system. Physiologists are not agreed as to the precise rôle which the brain plays, but the following conception has much to recommend it. There is in the medulla oblongata a "centre," *i.e.*, something analogous to a telephone exchange from which rhythmical messages pass down the nerves which connect it with the muscles of respiration. The principal nerves in question are the phrenic (4th cervical) nerves which supply the diaphragm and the intercostal nerves which supply the intercostal muscles. If the mechanism consisted merely of this centre and the motor nerves which it operates, respiration would be of a very curious type; for, apart from controlling influences, the natural rhythm of the centre is one which produces a series of gasps at slow intervals. Pursuing the analogy of the telephone exchange, the particular centre immediately responsible for the primitive gasping type of respiration, and known as the "respiratory" centre, is of the nature of a local exchange and is governed by two other centres in the brain, each of which modifies the natural gasping rhythm. One such centre imparts an inspiratory bias to the gasping rhythm, so that the respiration of an animal possessing these two centres, and these only, consists of infrequent respiratory efforts between which the lung is distended and therefore full of air. The third centre in the brain imparts the smoothness and a rate which gives respiration a more normal character.

Even so, there are other influences which conspire to impart the usual rhythm to breathing. They come from without the central nervous system, and the most important of them arrive from the lung itself, along the vagus nerve.

As has been shown by Hering and Breuer, and by Head, at each phase of respiration a message is sent from the lung up the vagus. The precise nature of this message is unknown, whether it merely demands the termination of that particular phase, or whether it demands the initiation of the next, or both, is uncertain; the certain thing is that the change from inspiration to expiration (and vice versa) which would take place in time apart from vagus influences, is accelerated by them, so that respiration is more rapid and less deep with the vagi intact than with them cut. Animals will, however, live for a long time without their vagi, and when they die it is not because the power of respiration is deficient. Of the other nerves which lead to the brain, that which most influences respiration is the fifth cranial nerve, as is shown when strong ammonia is placed beneath the nose. The sensory nerves from almost any part of the skin, too, can influence respiration, as when cold water is suddenly dashed on to the surface of the body.

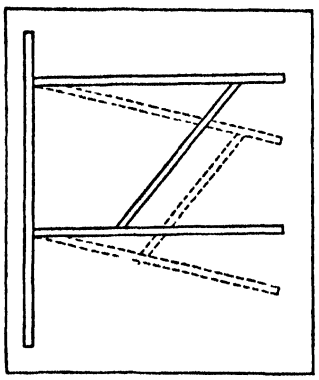

FIG. 7.—MODEL OF PAIR OF RIBS

Types of Respiration.—The visible characters of respiration in man vary considerably according to age and sex. In men, while there is a moderate degree of upheaval of the chest, there is a considerable, although not preponderating, degree of excursion of the abdominal walls. In women the chest movements are decidedly most marked, the excursion of the abdominal walls being comparatively small. Hence we may distinguish two types of respiration, the costal and the abdominal, according to the preponderance of movement of one or the other part of the body wall. In forced respiration the type is costal in both sexes, and so it is also in sleep. The cause of this difference between men and women has been variously ascribed (*a*) to constriction of the chest by corsets in women, (*b*) to a natural adaptation to the needs of childbearing in women, and (*c*) to the greater relative flexibility of the ribs in women permitting a wider displacement under the action of the inspiratory muscles.

In healthy breathing the mouth should be closed and the ingoing current should all pass through the nose. When this happens the nostrils become slightly expanded with each inspiration, probably by the action of the M. dilatores naris. In some people this movement is hardly perceptible unless breathing be heavy or laboured. As the air passes at the back of the throat behind the soft palate it causes the velum to wave very gently in the current; this is a purely passive movement. If we look at the glottis or opening into the larynx during respiration, as we may readily do with the help of a small mirror held at the back of the throat, we may notice that the glottis is wide open during inspiration and that it

becomes narrower by the approximation of the vocal chords during expiration. This alteration is produced by the action of the laryngeal muscles. Like the movements of the nostril, those of the larynx are almost imperceptible in some people during ordinary breathing, but are very well marked in all during forced respiration.

GASEOUS EXCHANGE

The extent of gaseous exchange in man varies greatly with the size and age of the person, the degree of activity, etc.

	O_2 consumption in cu. cm. per min. at 0° C and 76 mm. (Haldane)	CO_2 production in cu. cm. per min. at 0° C and 76 mm. (Haldane)	Litres of air breathed per min. at 37° C, moist and at the prevailing barometric pressure
Rest in bed	237	197	7·67
Rest—standing	328	264	10·4
Walking on grass:			
2 miles an hour	780	662	18·6
3 " " "	1,065	992	24·8
4 " " "	1,595	1,398	37·3
4½ " " "	2,005	1,788	46·5
5 " " "	2,543	2,386	60·9

The absolute minimum of oxygen consumption for any person is known as the basal metabolism and is that which takes place when the person is at rest in bed some ten hours after a meal. The basal metabolism in persons of different size, but otherwise comparable, varies not proportionately to the weight but to the body surface (*see* ANIMAL HEAT) and is therefore expressed in calories (*i.e.*, in units of heat produced) or in oxygen consumed per square metre of body surface per hour.

The basal metabolism varies with age, thus:

Mean age (years)	Basal metabolism per sq. metre per hour	
	Calories	Oxygen used litres (approx.)
6.	57·5	11·7
12·6	50·4	10·3
13·7	49·4	10·1
16·5	43	8·73
19·25	40·7	8·30

In warm blooded animals the total ventilation varies with the size of the organism, being more intense the smaller the creature.

	Man	Goat	Rabbit	Guinea pig	Rat	Mouse
Total ventilation in litres per kg. per minute	·1	·2	·4	·6	1·5	5·1

The reason is as follows: The capacity for heat loss depends upon the superficial area of the animal. The heat production naturally must equal the heat loss; therefore the heat production must also vary with the superficial area, *i.e.*, in some way proportionally to the square of the linear dimensions on the animal. The weight, however, bears in proportion not to the square but to the cube; therefore, as the animal gets larger its area becomes relatively less proportionally to its weight, *i.e.*, the heat production, and therefore the degree of oxidation per gram of animal diminishes as the size increases. If the amount of oxygen required per gram of animal diminishes, the whole mechanism for its supply and therefore the total ventilation will diminish correspondingly.

The exchange of gases in the lung is regarded by almost all authorities as being a process of *diffusion*, the oxygen diffusing from the alveolar air through the pulmonary epithelium into the blood which circulates through the capillaries in the alveolar wall. (The most notable opponents of this view are Dr. J. S. Haldane, F.R.S., and some of those who have been associated with him. His views are fully set forth in his book *Respiration*.) The carbon dioxide likewise is regarded as passing by diffusion out of the blood into the alveolar air.

Transport of the Oxygen.—Oxygen constitutes about 14% of the moist air which fills the pulmonary alveoli and therefore exerts a pressure of a little over 100 mm. of mercury. In order that blood exposed to so low a pressure should carry away any considerable quantity of the gas, it must needs be a fluid possessing very special qualities. These qualities blood owes to the red pigment in the corpuscles—haemoglobin. This material can unite with large quantities of oxygen at a pressure not exceeding 100 mm. of mercury and so leaves the lung charged with oxygen. But what is more remarkable—haemoglobin gives up this oxygen again when exposed to lower oxygen pressures. Thus, at about 30 mm. of mercury the blood surrenders one-half of the oxygen united to it; at 20 mm. it gives up about three-quarters and so on. The curve which represents the relation between the quantity of oxygen united with the haemoglobin in blood, and the pressure of oxygen to which the blood is exposed, is called the oxygen dissociation curve.

There is one synthetic substance which attaches oxygen to itself if exposed to more than a certain critical pressure of that gas and from which the oxygen escapes if the oxygen pressure drops below the critical point—that substance which has recently been discovered by Prof. Moureu is rubrine, a complicated hydrocarbon. Though rubrine and haemoglobin seem to unite with oxygen after a manner not wholly dissimilar and, so far as other oxides are concerned, unique, they are otherwise not at all alike. Rubrine consists of three benzine rings united in a way not at present ascertained. Haemoglobin consists of a protein united with haematin, a substance which contains iron on the one hand and four pyrrol rings on the other. Moreover, it is clear from spectroscopic and other evidence, that the attachment of the oxygen to the haemoglobin has some relation both to the iron and to the pyrrol constitution of the substance. The constitution and properties of haemoglobin are of great theoretical importance because, but for it, the warm blooded animal could never have developed the high degree of vitality which he possesses. Oxygen is so insoluble in water that, apart from haemoglobin, blood could only carry to the tissues about one-sixtieth part of the quantity of oxygen which it does; therefore to maintain oxidation in the tissues at its normal level 60 times as much blood would have to circulate as at present. As the blood already forms one-fifteenth of the weight of the body, without haemoglobin it must needs form four times the weight of the rest of the body—an impossible burden. There are in the lower forms of life some respiratory pigments not altogether dissimilar from haemoglobin. In the blood of some worms, for instance, is found a ma-

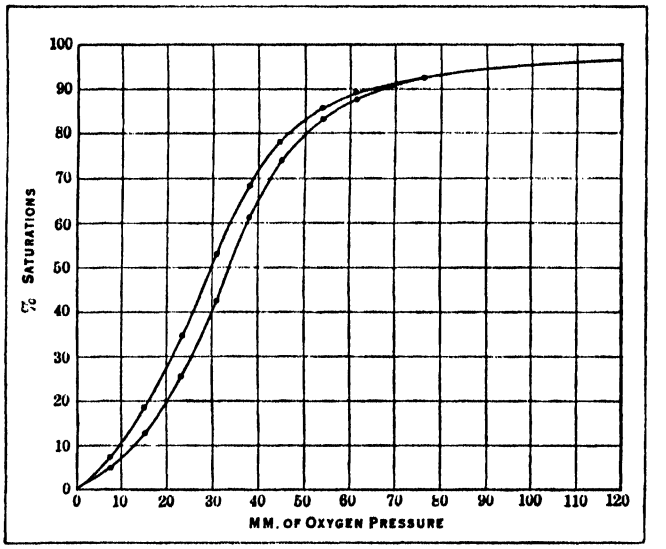

FIG. 8.—OXYGEN DISSOCIATION CURVES—ARTERIAL BLOOD AND VENOUS BLOOD (ADAPTED FROM HALDANE)
Ordinate represents percentage and saturation with oxygen, Abscisse, pressure of oxygen in mm. of mercury

terial chlorocronorin, which is really a form of haemoglobin, but possessed of a somewhat different scaffold of porphyrin. In some of the molluscs is found haemocyanin, also a protein body containing not iron but copper, and which, moreover, contains no porphyrin. These bodies like haemoglobin possess the power of condensing, transporting and yielding oxygen under suitable conditions. The exact affinity of haemoglobin for oxygen is an example of nice adjustment of the conditions under which the haemoglobin is found to the needs of the body. The affinity varies according to the saline concentration of the medium in which the haemoglobin is dissolved, according to the hydrogen ion concentration and according to the temperature. Moreover, there appears to be an assortment of haemoglobins specific to the forms of life in which they are found, and which have affinities for oxygen suitable to those forms of life.

Transport of the Carbon Dioxide.—Carbon dioxide, unlike oxygen, is carried largely in the plasma; a small quantity is in physical solution, but the major portion is in chemical combination as sodium bicarbonate. The relative quantities in solution and in chemical combination regulate the reaction (degree of acidity or alkalinity) of the blood. The equation which connects the concentration of hydrogen ions (*see* HYDROGEN IONS, DETERMINATION OF) c_H to the concentration of carbon dioxide (CO_2) in solution, V_{CO_2} and in chemical combination B_{CO_2} is

$$c_H = k_1 \frac{V_{CO_2}}{B_{CO_2}}$$

It is often expressed logarithmically as:

$$-P_H = Pk_1 + \log V_{CO_2} - \log B_{CO_2}.$$

To say that the carbon dioxide is present chiefly in chemical combination as sodium bicarbonate ($NaHCO_3$) gives but a partial picture of its relation to the blood. Such a combination by itself would be very stable, and while it might provide a medium of suitable hydrogen ion concentration would not present the all-important property of absorbing and parting with large quantities of carbon-dioxide with very little reaction and with very little alteration in the partial pressure of carbon dioxide to which the blood is exposed. This double purpose is achieved by the presence in the blood of other acids, notably haemoglobin, which do not unite with carbon dioxide, but which compete with it for the sodium. The full beauty of the mechanism is only seen, however, when it is realized that haemoglobin is a stronger acid in combination with oxygen than when reduced. Now in passing through the tissues the moment when the blood requires to unite with carbon dioxide is also the moment at which it looses oxygen; at that moment, therefore, the haemoglobin becomes less strongly acid, and a base is therefore liberated with which the carbon dioxide can unite. The reverse series of changes takes place in the lung. As the oxygen unites with the haemoglobin, that material becomes more strongly acid, claims more of the base, and so displaces carbon dioxide, raising the partial pressure of that gas and therefore assisting its diffusion from the blood.

Diffusion of Gases Through the Pulmonary Epithelium.—With this understanding of the chemical processes which enable large quantities both of oxygen and carbon dioxide to pass into and out of the blood, as the result of only very small alterations in the pressure of those gases in the medium to which the blood is exposed, let us return to the proof of the general thesis that the passage of gases through the pulmonary epithelium is due simply to diffusion.

The basal principle of diffusion is that the quantity of gas which passes through a given membrane depends upon the difference of pressure of the gas on the two sides of the membrane. Regarding the lung as a membrane through which gas diffuses, Q being the quantity of oxygen which will pass through it per minute, P the pressure of oxygen in the pulmonary alveoli, T the mean pressure of oxygen in the capillaries of the lung, and k a coefficient depending upon the area and nature of the lung, then

$$Q = k(P-T);$$

k may be defined as the quantity of gas in cubic centimetres which will pass through the pulmonary epithelium per minute, with a difference of pressure of 1 mm. of mercury between the oxygen on the two sides of the membrane.

If the diffusion theory is correct, then not only must P be always greater than T, but their relations must be such as to allow of quantities of oxygen ranging from 200 cu.cm. at rest to perhaps 3,000 during extreme activity, being driven through the pulmonary epithelium per minute. As all the quantities Q, k, P and T are susceptible of independent measurement, it should be possible to form a judgment of the applicability of the equation. The simplest case is the condition of rest. The following measurements of k are given for 11 men, all of good physique at rest.

DIFFUSION COEFFICIENT OF LUNG CU.CM. OF O_2

Individual	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
D. C. of L.	25	32	36	38	42	43	43	43	45	45	65

Assuming that each of these men was absorbing 250 cu.cm. per minute, the mean difference of pressure $(P-T)$ between the oxygen in the alveolar air and capillary blood would have to be

MEAN DIFFERENCE OF PRESSURE IN MM.

Individual	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
Mean	10	8	7	7	6	6	6	6	6·5	5·5	4

These figures lead to the conclusion that at rest the pressure of oxygen in the alveolar air exceeds the average pressure in the capillary blood by about 6 mm. of mercury in the majority of well-developed persons. The average pressure in the capillaries is, of course, less than the pressure in the arteries and greater than that in the veins. Other data known concerning the individuals on whom these experiments were made lead to the conclusion that 6 mm. for the value of $(P-T)$ when Q is 250 cu.cm. may likely enough be correct. Greater difficulties arise when Q becomes, say, 2,500 cu.cm. during degrees of activity of which probably all the above persons would have been capable. If the diffusion coefficient still remains on the average 40 cu.cm. the value of $(P-T)$ would become 62·5 mm. It is hardly possible that the pressure of oxygen in the lungs should exceed the average pressure in the capillaries by so great an amount. We are therefore thrown back upon the position that in violent exercise the diffusion coefficient must alter, and there seems little doubt that an alteration on a sufficient scale takes place.

The Regulation of Respiration.—When active exercise is taken both the depth and the rate of respiration are as a rule increased. The increase is effected by one or both of two mechanisms; of these the first to be considered is nervous, the second chemical. The nervous factor in the regulation of respiration has been well illustrated by the following experiment, devised by Krogh and Lindhart. The subject is placed on a bicycle ergometer of a special type, *i.e.*, a bicycle which, instead of progressing, is made to work against a brake, the actual work done being measured by the brake. In this case the brake was an electromotor, the resistance to the worker and hence the work which he performed in overcoming it could be regulated by adjustment of the current passed through the motor. When work was commenced there was an immediate increase in the rate of depth of respiration and also in the pulse rate. Had these alterations been due to the stimulating action of chemical products formed in the muscle on the respiratory centre, enough time must have elapsed to allow of the products being taken up by the blood, carried to the heart, passed through the lungs and driven to the brain. These processes would have occupied upwards of half a minute. In point of fact, the augmentation of respiration came about much more quickly—in about five seconds from the commencement of the exercise. An even more striking experiment of the same sort was the following: The apparatus being as before the subject was lead to suppose that the load on the machine (and consequently the exercise he was to take) was to be suddenly and largely increased by throwing in a powerful current. Actually the current was not thrown in, though the pantomime of closing the switches,

etc., was gone through. The pulse and respirations were augmented as before, though no extra work was done by the subject. Clearly, therefore, the increased respiratory efforts were not due to chemical products produced by the work.

The chemical regulation of respiration was first clearly set forth by Haldane and Priestly, the demonstration of it following immediately on their discovery of a satisfactory method of determining the composition of alveolar air. The essential point emerged that at various altitudes which ranged between that of the top of Ben Nevis and the bottom of the Dolcoath mine, although the percentage of carbon dioxide in the alveolar air alters, the percentage becoming lower as the barometric pressure increases, the actual partial pressure of carbon dioxide in the alveoli and hence the concentration of that gas in the blood remains at such altitudes almost unchanged. This constancy of the pressure of carbon dioxide in the alveolar air means that the greater the barometric pressure the more the carbon dioxide produced by the body is diluted in the lung. As the carbon dioxide produced by the body is approximately constant in amount, the total ventilation of the lung, and hence the respiratory efforts must be greater the higher the barometer and the lower the altitude. Any effort to increase the carbon dioxide pressure in the blood, as by inhaling carbon dioxide or shedding it into the blood as the result of muscular exercise, has the effect of stimulating the respiratory centre and increasing the respiratory efforts more especially as regards the depth of respiration.

Controversy has ranged round the question of whether carbon dioxide is a specific stimulus to the respiratory centre, or whether its presence in the blood acts indirectly and, by increasing the concentration of hydrogen ions, stimulates the centre; the hydrogen ions and not the carbon dioxide acting as the stimulus. In favour of the latter view is the fact that after violent exercise, when the hydrogen ion concentration of the blood is increased and concentration of carbon dioxide diminished (lactic acid being present in considerable quantities), breathing may still be very laboured. It is certain also that, as shown by Winterstein, the administration of other acids to animals will cause dyspnoea (laboured breathing). On the other hand, other acids do not produce at all so striking an effect as carbon dioxide.

It is probable that CO_2 does act not specifically but by virtue of its power of increasing the hydrogen ion concentration in the brain; and that its potency in this respect is due to the ease with which it diffuses from the blood into the tissue of the brain itself. It is ultimately the hydrogen ion concentration inside the nerve cells which constitute the respiratory centre which would affect their stimulation—a fact which has been stressed by Gesell. According to his conception, if the activity of the respiratory centre is heightened as the result of nervous impulses playing upon it, the cells themselves will work harder, produce more CO_2 and undergo a sort of secondary stimulation. In the language of wireless, the original nervous stimulus will be "amplified." Similarly, if the carbon dioxide in the blood be increased, that produced by the cells will be unable to escape and will stimulate the centre.

In the above description it has been assumed that the irritability of the cells, *i.e.*, the degree of response which any particular stimulus will provoke, remains constant. This is not so in all circumstances. Many drugs, such as morphia, depress the centre, but the most interesting case of altered irritability of the centre is that of oxygen want (*see* ANOXAEMIA). If the respiratory centre be insufficiently supplied with oxygen over considerable periods of time the irritability is heightened, a given amount of exercise will then produce a much greater degree of breathlessness than it evokes in normal circumstances.

Temperature has an important effect upon respiration. This is less marked in man than in animals, which do not sweat; if the dog or goat, for instance, lies in the sun, shortly the respiration will become very rapid and shallow, a great volume of air will pass in and out of its respiratory passages, but the amount of air which ventilates the alveoli is not correspondingly increased. This alteration in the type of respiration (tachypnoea) may, in part, be due to rise in the temperature of the blood. If this blood, as it passes through the carotid artery to the brain be warmed, tachypnoea results. But tachypnoea is probably also helped by a reflex nervous mechanism initiated by the actual heating of the skin, for it is claimed that the temperature of the blood may even be lowered. The purpose is clear. The heat loss is, of course, proportional to the amount of aqueous vapour which leaves the body, and the aqueous vapour in its turn is roughly proportional to the total ventilation. Therefore, by establishing a large total ventilation the body temperature is kept from rising, but if there were also a large alveolar ventilation the loss of carbon dioxide would be too great, the respiration being, however, shallow the alveolar ventilation is not greatly increased.

Tissue Respiration.—The ultimate object of respiration is to supply each tissue in the body with the oxygen required, and to carry off the carbon dioxide produced. Different tissues require very different quantities of oxygen, and even the requirements of the same tissue vary greatly according to the degree of activity which they exhibit. Speaking generally, the tissues which show the highest basal metabolism are those which contain the greatest amount of nuclear tissue. Thus glandular organs for the most part have a resting metabolism of from ·05–·01 cu.cm. per gram per minute, while muscle at rest has an oxygen requirement in the next decimal place. The figures below refer to the dog or cat under anaesthetic conditions.

	Oxygen requirement per gram of resting organ per minute
	cc.
Suprarenal gland	0·045
Submaxillary gland	0·03
Pancreas	0·03
Kidney	0·03
Intestines	0·02
Liver (fasting animal)	0·02–0·01
Voluntary muscle	0·003
Unshaped muscle	0·004
Heart	0·007

The exchange of gases between the capillaries and the actual tissue cells is the converse of what takes place in the lungs; oxygen leaves the blood and passes into the tissues; carbon dioxide leaves the tissues and passes into the blood. As there is not known to be any mechanism other than diffusion for effecting this transference, it follows that the oxygen pressure in the tissues must be lower than that in the venous blood, and the carbon dioxide pressure higher.

The pressure of oxygen in the tissues is regulated by (1) the rate at which oxygen is being used, and (2) the rate at which it is being supplied. The former depends upon the activity of the organ, the latter on nature of the blood supply, *i.e.*, the quantity of blood which circulates through the organ, the surface which it presents in the capillaries, and the pressure of oxygen which exists in the capillary blood. All these factors are subject to considerable variations. The mean oxygen pressure in the capillary blood being perhaps the least inconstant, and being in the region of 40 mm. of mercury. The variations in oxygen consumption in various organs are very great. In skeletal muscle the oxygen used per gram of muscle per minute varies from 0·003 to 0·08 cu.cm. The mechanism by which the quantity of blood to organs is regulated is discussed in VASCULAR SYSTEM.

The variations in the surface which the blood presents have been investigated recently by Krogh; in the resting organ relatively few of the capillaries are open; as the activity of the organ increases the number of open capillaries increases also, so that the surface of blood from which diffusion can take place is very much increased. Information on the subject of what happens to the oxygen when it arrives in the cell is still rather obscure, but much work has been carried out since the World War and the following statements may perhaps be made:

(1) As a model the following reaction may be considered: In the presence of a ferrous salt (A) and hydrogen peroxide (B) the oxygen of the air will oxidize butyric into aceto-acetic acid.

(2) In potatoes in the presence of some substance A, which plays the same rôle as a ferrous salt and which is precipitable by alcohol, a lecithin-like substance is turned into a peroxide B which in air will oxidize, guiacum turning it blue. The lecithin-like substance is not precipitated by alcohol. The substance A is called a *peroxidase*, the substance forming B is called an *oxygenase*, or auto-oxidizable substance. The associate *oxygenase* and peroxide are together called an *oxidase system*. This type of system seems to exist in many vegetable cells.

(3) A material glutothione was discovered by Hopkins in 1921 in most animal and some other tissues. This material is probably capable of forming hydrogen peroxide and so playing a rôle similar to an oxygenase. Certain material contents of the animal cell known as "thermostable tissue residues" which are only oxidized very slowly in air, become oxidized rapidly if a little glutothione be added.

(4) Peroxidases are present in most animal tissues; of these one called cytochrome is known in some detail. It contains iron and is nearly related to the haemoglobin of blood.

THE RESPIRATION OF INJURIOUS ATMOSPHERES

Carbon Dioxide.—Until within recent years it was supposed that carbon dioxide was harmful when inhaled even in small quantities. In any but the most recent textbooks the estimates of the quantity of air necessary for the efficient ventilation of a room are based on the assumption that the carbon dioxide present must not rise above a certain level. The figure usually given is 0·1%. This rule is probably not a bad one, but it is now known that carbon dioxide in such small quantities is quite innocuous and even in much greater quantities would have to be breathed before an injurious level was reached. Men can inhale 5% for some hours without suffering from much more than discomfort, and untutored persons would not be conscious of the presence of 2% of carbon dioxide in the air if it were otherwise pure.

The rule that the air of dwelling rooms should not contain more than 0·1% carbon dioxide is therefore useful, because air laden beyond that limit with carbon dioxide is also probably laden with other things to an injurious degree.

Meaning of "Ventilation."—Indeed the connotation of the word "ventilation" has been rendered somewhat vague by the more recent discoveries of science. If the use of the word be stretched to cover such sources of health as may be secured by the practice of opening the window, there are at least four such. (1) The removal of aqueous vapour; (2) the movement of air over the skin; (3) the removal of germs, and (4) the admission of ultra-violet rays of light.

Considering the above points, the benefits of ultra-violet rays are treated elsewhere (LIGHT and RADIATIONS in relation to health). Here it is only necessary to say that ordinary window glass is relatively opaque to ultra-violet light and even specially manufactured glasses are often much less penetrable than is the open window. The beneficial effects of changing the air in a room on the disposition of germs has been demonstrated beyond dispute by experiments carried out by Leonard Hill. He dissipated a certain number of germs into a room with the windows shut; 20 min. later he exposed a plate of gelatine and found on it 39 germs. On a second occasion he dissipated the same number of germs into the room, opened the windows, and on exposure of the plate after 20 min. only one germ settled on it.

The advantage of keeping the air in motion may be illustrated by the following experience. On two successive days (on each of which the outside air was hot and still) a small over-crowded room was occupied for 8 hours by 11 typewriting clerks at work, a doctor and two experimenters. On the first day all avenues of ventilation were as far as possible closed, the chimney stuffed up, curtains put over the doors, etc., but the air in the room was actively circulated by electric fans. The percentage of carbon dioxide rose to about 2%. On the second day the fans were not in motion, but panes were abstracted from the windows. Chemical analysis showed that the air, though still, was pure. The stenographers who were unaware of the point of the experiment agreed that the conditions were more tolerable the first day than the second, and examination of their work bore out that statement. The benefits of movement are probably due to two causes: (1) the actual stimulating effect of moving air passing over the skin, and (2) the fact that moving air evaporates moisture from the skin much more readily than still air. The relative importance of these factors probably differs much in different persons. The moral of the above experiment is not to disparage purity. It is to emphasize the necessity of combining purity with movement.

Carbon Monoxide and Coal Gas.—For the theory of carbon monoxide poisoning see ANOXAEMIA and BLOOD. Here it need only be said that the following are given as the percentages of carbon monoxide in the air which must be inhaled to produce the results stated.

Time and concentration	=	300 or less, no perceptible effect
" " "	=	600, a just perceptible effect
" " "	=	900, headache and nausea
" " "	=	1,500, dangerous.

In the above table time is measured in hours and the concentration in parts of carbon monoxide per million of air. The figures assume that the subject is at rest and inhaling about seven litres of air per minute. If he is active and therefore inspiring greater quantities of air, the time necessary to produce death or unconsciousness is cut down directly in proportion to the magnification of the quantity of air breathed per minute.

In practice it is not easy to attain the concentrations of carbon monoxide necessary to produce fatal results. The experiments of Haldane have shown that the walls of ordinary dwelling rooms are quite permeable to the gas. This fact, together with the gradual movement of air, even through ill-ventilated rooms, as a rule prevents dangerous concentration of carbon monoxide being maintained, even where there is a slight escape of gas.

High Atmosphere Pressure.—Where men work under water at considerable depth, it is necessary to supply them with air at a pressure as great as, or greater than, the combined pressure of the atmosphere and of the water under which they are working. Unless the pressure be very high this in itself has no injurious effects and men may go confidently and quickly into such pressures; great care, however, must be exercised in emerging from a high atmospheric pressure into a normal one. The danger is due to the nitrogen dissolved in the blood. The quantity of this gas held in solution in the blood depends upon the pressure of oxygen to which the body is exposed. Normally, each litre of blood holds about 15 cu.cm. of nitrogen; at depths of 33 ft. under water the pressure of air in the diving apparatus would be two atmospheres, in which case each litre of blood would hold 30 cu.cm. of gas in solution. As the gas is not removed by the formation of any chemical compounds with other materials in the body, when the pressure is lowered it forms minute bubbles of nitrogen in the plasma. These bubbles when carried to the capillaries form emboli. Indeed, the danger is not confined to the blood, for if the worker be long enough exposed to the high pressure, all juices which permeate all the tissues of the body become charged with abnormally large quantities of nitrogen which, when the pressure is reduced, renders itself evident by the formation of small bubbles. These appear in many situations in the body, notably in nerve cells in the brain and elsewhere. Such bubbles are the cause of the condition known as "bends" associated with pain and paralysis, which may be even fatal.

Chlorine.—The inhalation of chlorine in concentration of more than one part per million of air for an indefinite period is dangerous; for half-an-hour the maximum allowable is four parts per milion; 40 to 60 even for short periods is dangerous. Chlorine is typical of a number of gases which produce inflammation of the lungs, death being due not directly to the gas, but to asphyxia. It is of particular historic interest as being the first gas used on a large scale as a lethal weapon in war; clouds of the gas being liberated from cylinders in the German lines were carried by the favourable wind over to the lines of the Allied armies, where it produced the most devastating effect. More potent asphyxiants than chlorine, but much less used in commerce, are phosgene

and chloropicrin. Other gases which act similarly are sulphuretted hydrogen, sulphur dioxide, nitrous acid and acid fumes.

Other Gases Having Deleterious Effects.—*Hydrocyanic or Prussic Acid* is much used for the fumigation of passenger steamers in port; for while poisonous to practically all forms of animal life, including vermin, it does not attack paint work. It is invisible and though it has a distinctive odour, the nose rapidly becomes deadened to the smell, so that persons may easily walk into stronger concentrations of the gas, being deceived by his nose into the idea that he is walking out of it. When the ship is opened up after fumigation particular care must be taken that fatal concentrations of the gas do not remain in pockets. Canaries are much more sensitive to HCN than men, and may be used to detect the gas.

Aniline, Nitrobenzine and other bodies which contain NH_2, NO, and NO_2 groups, are met with in the dye industry and in the manufacture of explosives; their action is to appropriate the haemoglobin of the blood, turning it temporarily into methaemoglobin. (*See* ANOXAEMIA.) The following table gives an idea of their toxicity.

	Parts per million of air		
	Nitrobenzine	Aniline	Toluidine
Slight symptoms after several hours exposure. Maximum amount that can be inhaled for 1 hour without serious disturbance . . .	0·2–0·4 1·0	7·0–26·0 105–170	6–23 91–140

Sulphides of Arsenic, Phosphorus and Hydrogen.—*Arsene* sometimes contaminates the air in the vicinity of storage batteries, for the charging of which impure sulphuric acid is being used. Thus in submarines whole crews may be affected. The poison is a cumulative one; small quantities inhaled accumulate in the body until a toxic concentration is reached. *Phosphine* is evolved when water acts on calcium phosphide and is used as an illuminating gas, in buoys, etc. *Hydrogen sulphide* may contaminate the air in chemical works, but is more frequently the cause of accident in sewers, where sewer gas may accumulate in pockets. Toxicity:

	Parts per million parts of air		
	Arsine	Phosphine	Hydrogen sulphide
Maximum amount which can be inhaled for one hour	50	100–200	200–300
Rapidly fatal . .	250	2,000	1,000–3,000

Dichlordiethylsulphide—the so-called "mustard gas" or "Yperite"—was by far the most devastating gas used in the World War. It owed its potency largely to the fact that it was extremely indestructible, contaminating the ground and giving off small quantities of vapour which, if breathed for long periods of time, produced an inflammation of the respiratory passages which was either itself fatal or was liable to doom the lung to subsequent infection by bacteria. This gas also caused intense inflammation of the eyes and blistering of the skin.

Toxic Smokes such as dichlorarsine and dicyanarsine which when inhaled caused intense irritation of the nose and throat, leading to uncontrollable fits of sneezing and coughing, were also used as shell fillings in the World War.

Respirators.—Both in war and in industry the entry of poisonous gases into the respiratory system is prevented by the use of respirators. These are of two general types:

1. *The oxygen breathing set* consists of an air-tight mask (*a*) connected to a cylinder supplying oxygen; and (*b*) containing a cartridge of soda-lime or some other absorbent of carbon dioxide. The whole apparatus is self-contained, so that the subject has not and need not have access to the outer air. This form of apparatus is particularly useful in atmospheres containing carbon monoxide, *e.g.*, the air in mine galleries after an explosion, and is indispensable to rescue parties.

FROM HAGGARD AND HENDERSON, "NOXIOUS GASES" (CHEMICAL CATALOG CO.)

FIG. 9.—GAS MASK IN SECTION

2. In various forms of respirators the mask is attached to a canister containing some chemical absorbent. The outer air is inhaled during inspiration, but on its way this air is filtered through the absorbent and so rid of the poisonous principle. The expired air passes out from the mask through a valve. Naturally the absorbent employed depends upon the nature of the poison to be met.

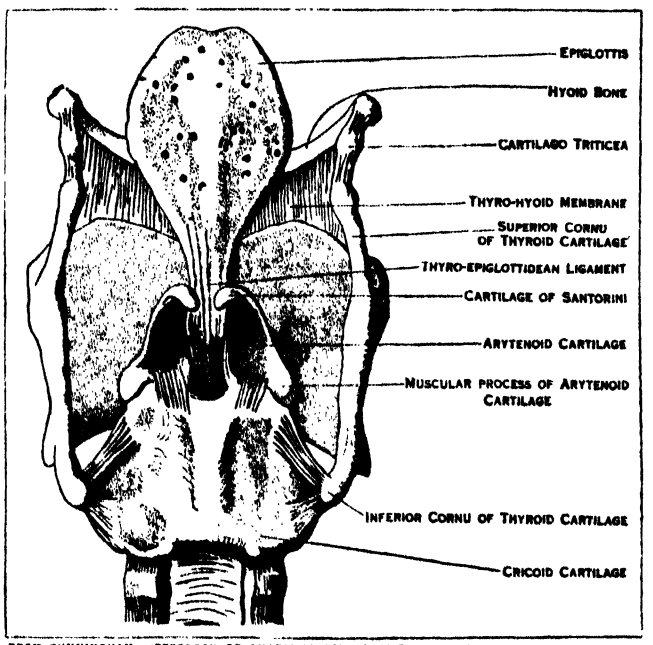
RESPIRATORY SYSTEM, ANATOMY OF. The respiratory tract consists of the nasal cavities, pharynx, larynx, trachea, bronchi and lungs. For the first two parts *see* OLFACTORY SYSTEM and PHARYNX.

Larynx.—The *larynx* is the upper part of the air tube specially modified for the production of notes of varying pitch, though it is not responsible for the whole of the voice. Its framework is made up of cartilages which are moved on one another by muscles, and it is lined internally by mucous membrane. The larynx is situated in the front of the neck and corresponds to the fourth, fifth and sixth cervical vertebrae. For its superficial anatomy *see* ANATOMY, *Superficial and Artistic.*

The *thyroid cartilage* is the largest in the larynx and consists of two plates or *alae* joined in the mid-ventral line. At the upper part of their junction is the *thyroid notch* and just below that is a forward projection, the *pomum Adami* ("Adam's apple"), best marked in adult males. From the upper part of the posterior border of each *ala* the *superior cornu* rises up to be joined to the tip of the great cornu of the hyoid bone by the *lateral thyro-hyoid ligament,* while from the lower part of the same border the *inferior cornu* passes down to be fastened to the cricoid cartilage by the *crico-thyroid* capsule. From the upper border of each ala the *thyro-hyoid membrane* runs up to the hyoid bone, while near the back of the outer surface of each the *oblique line of the thyroid cartilage* runs downward and forward.

The *cricoid cartilage* (*see* figs. 1 and 2) is something like a signet ring with the seal behind; its lower border, however, is horizontal. To the mid-ventral part of its upper border is attached the mesial part of the *crico-thyroid membrane,* which attaches it to the lower border of the thyroid cartilage; the lateral parts of this membrane pass up internally to the thyroid cartilage and their upper free edges form the true *vocal cords.* On the summit of the signet part of the cricoid are placed the two *arytenoid cartilages* (*see* fig. 2), each of which forms a pyramid with its apex upward. The base articulates with the cricoid by a concave facet, surrounded by the *crico-arytenoid capsule,* and the two arytenoids can glide toward or away from one another, while each can rotate



round a vertical axis. From the front of the base a delicate process projects which is attached to the true vocal cord (*vocal process*), while from the outer part of the base a stouter process attaches the two crico-arytenoid muscles (muscular process).

FIG. 1.—PROFILE VIEW OF CARTILAGES AND LIGAMENTS OF LARYNX

The *epiglottis* (*see* fig. 3) forms a lid to the larynx in swallowing; only the box moves up to the lid instead of the lid moving down to the box. It is leaf-shaped, the stalk being attached to the junction of the thyroid cartilages inside the larynx, while the anterior surface of the leaf is closely attached to the root of the

FIG. 2.—CARTILAGES AND LIGAMENTS OF LARYNX SEEN FROM BEHIND

tongue and body of the hyoid bone. The posterior or laryngeal surface is pitted for glands. All the cartilages of the larynx are of the hyaline variety except the epiglottis, the cornicula laryngis and the cuneiform cartilages, which are yellow elastic. The result is that all except these three tend to ossify as middle age is approached.

The *muscles of the larynx* are: (1) the *crico-thyroids*, attached to the lower border of the thyroid and the anterior part of the cricoid, by pulling up which they make the upper part of the signet, with the arytenoids attached to it, move back and so tighten the vocal cords. (2) The *thyro-arytenoids* (*see* fig. 4), which run back from the junction of the thyroid alae to the front of the arytenoids and side of the epiglottis; they pull the arytenoids toward the thyroid and so relax the cords. (3) The single

arytenoideus muscle, which runs from the back of one arytenoid to the other and approximates these cartilages. (4) The *lateral crico-arytenoids* (*see* fig. 4) which draw the muscular processes of the arytenoids forward toward the ring of the cricoid and, by so doing, twist the vocal processes, with the cords attached, inward toward one another; and (5) the *posterior crico-arytenoids* (*see* fig. 4) which run from the back of the signet part of the cricoid to the back of the muscular processes of the arytenoid and, by pulling these backward, twist the vocal processes outward and so separate the vocal cords. All these muscles are supplied by the recurrent laryngeal nerve, except the crico-thyroid which is innervated by the external branch of the superior laryngeal (*see* NERVES, *Cranial*).

The *mucous membrane of the larynx* is continuous with that of the pharynx at the *aryteno-epiglottidean folds* which run from the sides of the epiglottis to the top of the arytenoid cartilages (*see* fig. 3). To the outer side of each fold is the *sinus pyriformis* (*see* PHARYNX). From the middle of the junction of the alae of the thyroid cartilage to the vocal processes of the arytenoids the mucous membrane is reflected over, and closely bound to, the true vocal cords which contain elastic tissue and, as has been mentioned, are the upper free edges of the lateral parts of the crico-thyroid membrane. The chink between the two true vocal cords is the *glottis* or *rima glottidis*. Just above the true vocal cords is the opening into a recess on each side which runs upward and backward and is known as the *laryngeal saccule;* its opening is the *laryngeal sinus*. The upper lip of this slit-like opening is

called the *false vocal cord.*

The mucous membrane is closely bound down to the epiglottis and to the true vocal cords, elsewhere there is plenty of submucous tissue. In the upper part of the front and sides of the larynx and over the true vocal cords the mucous membrane is lined by squamous epithelium, but elsewhere the epithelium is columnar and ciliated: it is supplied by the superior laryngeal

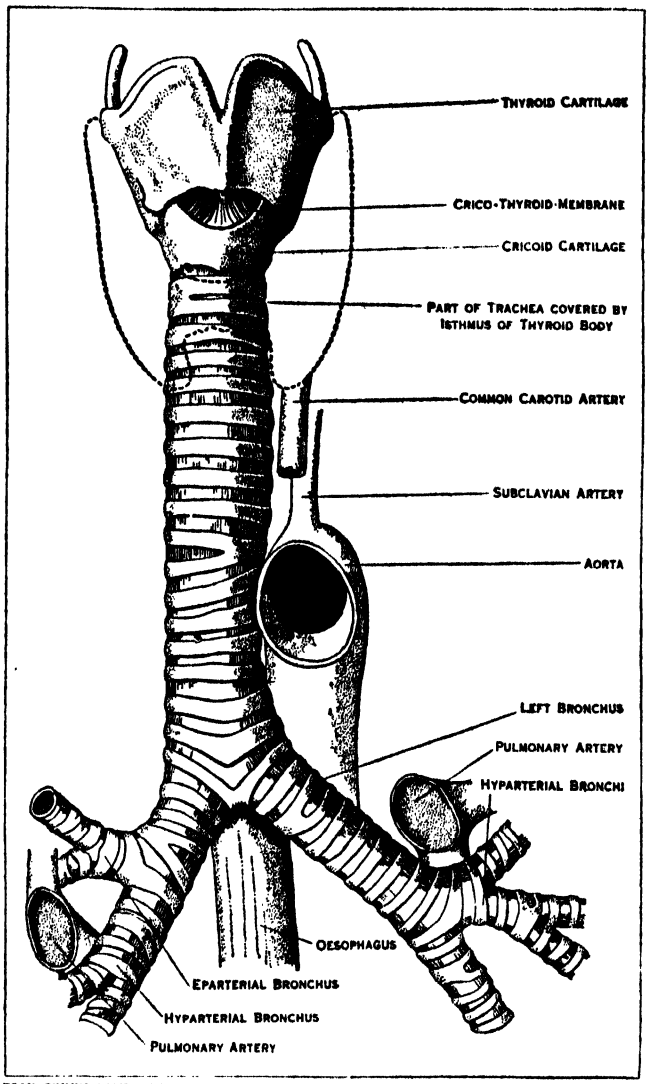
branch of the vagus nerve and above the glottis is peculiarly sensitive.



Trachea.—The *Trachea* or windpipe (*see* fig. 5) is the tube which carries the air between the larynx and the bronchi; it is from four to four and a half inches long and lies partly in the neck and partly in the thorax. It begins where the larynx ends at the lower border of the sixth cervical, and divides into its two bronchi opposite the fifth thoracic vertebra. The tube is kept always open by rings of cartilage, which, however, are wanting behind, and, as it passes down, it comes to lie farther and farther from the ventral surface of the body, following the concavity of the thoracic region of the spinal column. In the whole of its downward course it has the oesophagus close behind it, while in front are the isthmus of the thyroid, the left innominate vein, the innominate artery and the arch of the aorta. On each side of it and touching it is the vagus nerve.

The cervical part of the tube is not much more than an inch in length, but it can be lengthened by throwing back the head. This is the region in which tracheotomy is performed, and it should be remembered that in children, and sometimes in adults, the great left innominate vein lies above the level of the top of the sternum.

The trachea is made up of an external fibro-elastic membrane in which the cartilaginous rings lie, while behind, where these rings are wanting, is a layer of unstriped muscle which, when it contracts, draws the hind ends of the rings together and so diminishes the calibre of the tube. Inside these is plentiful submucous tissue containing mucous glands and quantities of lymphoid tissue, while the whole is lined internally by columnar ciliated epithelium.

Bronchi.—The *Bronchi* (*see* fig. 5) are the two tubes into which the trachea divides, but the branches, which these tubes give off later, are also called bronchi. Put shortly, they are two long tapering tubes which run from the bifurcation of the trachea to the lower and back part of each lung, and give off a series of large ventral and small dorsal branches. The upper part of each of these long tubes or *stem bronchi* is outside the lung and in the middle mediastinum of the thorax, the lower part embedded in the substance of the lung. The structure of the bronchi is practically identical with that of the trachea. (*See* G. S. Huntington's "Eparterial Bronchial System of the Mammalia," *Am. Journ. Med. Sci.* [Phila. 1898]. *See* also Quain's *Anatomy*, London, last edition.)

Lungs.—The *Lungs* are two pyramidal, spongy, very vascular organs in which the blood is oxygenated. They are pink normally, but, often in city dwellers are slate-coloured from local deposition of soot particles. Each lies in its own side of the thorax and is surrounded by its own pleural cavity (*see* COELOM AND SEROUS MEMBRANES), and has an *apex* which projects into the side of the root of the neck, a *base* which is hollowed for the convexity of the diaphragm, an outer surface which is convex and lies against the ribs, an inner surface concave for the heart, peri-

FIG. 5.—TRACHEA AND BRONCHI, INDICATING THE THYROID BODY BY A DOTTED LINE

cardium and great vessels, a sharp anterior border which overlaps the pericardium and a broad, rounded posterior border which lies at the side of the spinal column. Each lung is nearly divided into two by a *primary fissure* which runs obliquely downward and forward, while the right lung has a *secondary fissure* which runs horizontally forward from near the middle of the primary fissure. The left lung has therefore an *upper* and *lower or basal lobe*, while the right has *upper, middle* and *lower lobes*. On the inner surface of each lung is the *root* or *hilum* at which alone its vessels, nerves and ducts (bronchi) can enter and leave it.

The structures contained in the root of each lung are the branches and tributaries of (1) the *pulmonary artery,* (2) the *pulmonary veins,* (3) the *bronchi,* (4) the *bronchial arteries* which supply the substance of the lung, (5) the *bronchial veins,* (6) the *bronchial lymphatic vessels and glands,* (7) the *pulmonary plexuses of nerves.* Of these the first three are the largest and, in dividing the root from in front, the veins are first cut, then the arteries and last the bronchi. As the bronchi become smaller and smaller by repeated division, the cartilage completely surrounds them and tends to form irregular plates instead of rings—they are therefore cylindrical, but when the terminal branches (*lobular bronchi*) are reached, the cartilage disappears and hemispherical bulgings called alveoli occur (fig. 6 A). At the very end of each lobular bronchus is an irregular chamber, the *atrium* (fig. 6 B), and from this a number of thin-walled sacs, about 1 mm. in diameter, open out. These are called the *infundibula* (fig. 6 C), and their walls are pouched by hemispherical air-cells or alveoli like those in the lobular bronchi. Each lobular bronchus with its atrium and infundibula forms a *lobule* of the lung, and these lobules are separated by connective tissue, and their outlines are evident on the surface of the lung.

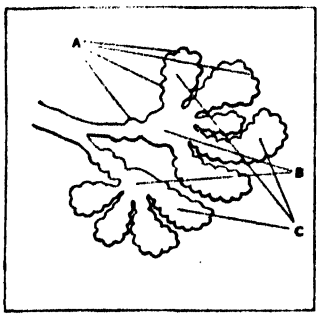

FIG. 6.—DIAGRAM OF TWO LOBULES OF THE LUNG

The muscular tissue, which in the larger tubes was confined to the dorsal part, forms a complete layer in the smaller; but when the lobular bronchi are reached, it stops and the mucous membrane is surrounded by the elastic layer. In the lobular bronchi, too, the lining epithelium gradually changes from the ciliated to the stratified or pavement variety, and this is the only kind found in the infundibula and alveoli. Surrounding each alveolus is a plexus of capillary vessels so rich that the spaces between the capillaries are no wider than the capillaries themselves, and it is here that the exchange of gases takes place between the air and the blood.
